The initiator shall initiate the MU-MIMO BF feedback subphase an MBIFS following the transmission of the EDMG BRP-RX/TX PPDU with the BRP CDOWN field set to 0. In the MU-MIMO BF feedback subphase, the initiator shall transmit a MIMO BF Poll frame to poll each remaining responder to collect MU-MIMO BF feedback from the preceding MU-MIMO BF training subphase. The TA field of each MIMO BF Poll frame shall be set to the BSSID of the initiator and the RA field shall be set to the MAC address of the corresponding responder. Each MIMO BF Poll frame carries the dialog token in the Dialog Token field that identifies the MU-MIMO BF training. In the MIMO Poll Control element of each MIMO BF Poll frame, the SU/MU field shall be set to 1 and the Poll Type field shall be set to 0. A SIFS after receiving a MIMO BF Poll frame for which a remaining responder is the addressed recipient, the responder shall transmit a MIMO BF Feedback frame to the initiator. The RA field of the MIMO BF Feedback frame shall be set to the BSSID of the initiator and the TA field shall be set to the MAC address of the responder. The MIMO BF Feedback frame carries the dialog token in the Dialog Token field that identifies the MU-MIMO BF training. In the MIMO Feedback Control element of the MIMO BF Feedback frame, the SU/MU field shall be set to 1 and the Link Type field shall be set to 0. If the MIMO BF Feedback frame contains MU-MIMO BF feedback, the ComeBack Delay field shall be set to 0. Otherwise, the ComeBack Delay field shall be set to a nonzero value that indicates when the responder is ready with MU-MIMO BF feedback.

If the ComeBack Delay field is 0 and for a 2.16+2.16 GHz or 4.32+4.32 GHz channel, the Channel Aggregation Present subfield of the MIMO FBCK-TYPE field should be set to 1. The Number of TX Sector Combinations Present subfield of the MIMO FBCK-TYPE field shall indicate the number of transmit sector combinations, N_{tsc}.

The EDMG Channel Measurement Feedback element in the MIMO BF Feedback frame shall indicate N_{tsc} transmit sector combinations in the EDMG Sector ID Order field and the BRP CDOWN field, which are obtained through the channel measurement data captured from the MU-MIMO BF training subphase. The Channel Measurement Feedback element in the MIMO BF Feedback frame shall indicate SNRs corresponding to N_{tsc} transmit sector combinations in the SNR field. If the Channel Measurement Requested subfield of the MIMO FBCK-REQ field in the MIMO BF Setup frame received from the initiator in the preceding MU-MIMO BF setup subphase is 1, the Channel Measurement Present subfield of the MIMO FBCK-TYPE field in the MIMO Feedback Control element shall be set to 1 and the Channel Measurement Feedback element shall contain the channel measurements corresponding to N_{tsc} transmit sector combinations in the Channel Measurement field. If the Tap Delay Requested subfield of the MIMO FBCK-REQ field in the MIMO BF Setup frame received from the initiator in the preceding MU-MIMO BF setup subphase is 1, the Tap Delay Present subfield of the MIMO FBCK-TYPE field in the MIMO Feedback Control element shall be set to 1 and the EDMG Channel Measurement Feedback element shall contain tap delays corresponding to the N_{tsc} transmit sector combinations in the Tap Delay field.

If the ComeBack Delay field of the MIMO BF Feedback frame received from the responder is nonzero, the initiator shall send a MIMO BF Poll frame with the SU/MU field set to 1 and the Poll Type field set to 0 to the responder immediately after the responder's comeback delay has elapsed subject to the DMG channel access rules in a DTI. In this case, the responder shall respond with a MIMO BF Feedback frame that contains the MU-MIMO BF feedback.

Each MIMO BF Poll frame and MIMO BF Feedback frame shall be separated by SIFS, except in the case that a MIMO BF Feedback frame includes a ComeBack Delay field set to a nonzero value.

The initiator shall initiate the MU-MIMO BF selection subphase an MBIFS following reception of the MIMO BF Feedback frame from the last remaining responder. In the MU-MIMO BF selection subphase, the initiator shall transmit one or more MIMO BF Selection frames to each responder in the MU group. The

initiator should transmit the minimum number of MIMO BF Selection frames to reach all responders in the MU group. The MIMO BF Selection frames should be sent using the DMG control mode. The TA field of the MIMO BF Selection frame shall be set to the BSSID of the initiator and the RA field shall be set to the broadcast address. Each MIMO BF Selection frame contains the dialog token in the Dialog Token field for identifying the MU-MIMO BF training. In the MIMO Selection Control element of each MIMO BF Selection frame, the MU-MIMO Transmission Configuration Type field shall be set to 0 and the Reciprocal MU-MIMO BF Training Based Transmission Configuration field shall not be present. The EDMG group ID corresponding to the MU group, which is the same as that is used in the MU-MIMO BF setup subphase, shall be indicated in the EDMG Group ID field and the number of MU-MIMO transmission configurations, N_{conf}, shall be indicated in the Number of MU-MIMO Transmission Configurations field.

Which responder(s) in the MU group is associated with each of N_{TX} TX DMG antennas for each of N_{conf} MU-MIMO transmission configurations shall be indicated in the Configuration i Group User Mask for Antenna j subfield (i = 1, 2, …, N_{conf} and j = 1, 2, …, N_{TX}) of the Nonreciprocal MU-MIMO BF Training Based Transmission Configuration field. The TX sector of each of N_{TX} TX DMG antennas and the corresponding RX AWVs or RX DMG antennas of all associated responders used in each of N_{conf} MU-MIMO transmission configurations shall be indicated in the Configuration i User k SISO ID Subset Index/ RX Antenna ID for Antenna j subfields (k = 1, 2, …, $N_{i,j}^{(u)}$, i = 1, 2, …, N_{conf} and j = 1, 2, …, N_{TX}) of the Nonreciprocal MU-MIMO BF Training Based Transmission Configuration field. In more details, if User k in Configuration i participated in the nonreciprocal MU-MIMO BF training, the Configuration i User k SISO ID Subset Index/RX Antenna ID for Antenna j subfield indicates the RX AWV of User k corresponding to TX DMG Antenna j in Configuration i from a receiver's perspective. Otherwise, the Configuration i User k SISO ID Subset Index/RX Antenna ID for Antenna j subfield indicates the RX DMG antenna of User k corresponding to TX DMG Antenna j in Configuration i.

Each MIMO BF Selection frame may include an EDMG Group ID Set element to update the MU group corresponding to the EDMG group ID indicated in the EDMG Group ID field of the MIMO Selection Control element or other MU groups.

The MU-MIMO transmission configuration to be used for MU-MIMO transmission is indicated using either a RTS frame with a control trailer or a DMG CTS-to-self frame with a control trailer at the beginning of a MU-MIMO channel access procedure (see 10.38.12.4.4 (MU-MIMO channel access procedure)).

10.41.10.2.3.5 MIMO phase—reciprocal

The reciprocal MIMO procedure might shorten the MU-MIMO BF training duration. The initiator may initiate a reciprocal MIMO phase procedure if the following conditions are met:

- The Reciprocal MU-MIMO Supported field in initiator's and intended recipients' EDMG Capabilities element equals one, and
- The Antenna Pattern Reciprocity field in the initiator's DMG Capabilities element equals one.

The reciprocal MIMO phase is shown in Figure 10-115 (Reciprocal MIMO phase of MU-MIMO beamforming) and consists of three subphases, namely, an MU-MIMO BF setup subphase, an MU-MIMO BF training subphase and an MU-MIMO selection subphase. Each subphase shall be separated by MBIFS.

Based on the feedback from the SISO phase, in the reciprocal MU-MIMO BF setup subphase the initiator may exclude some responders from the following reciprocal MU-MIMO BF training subphase. This might happen if the multiuser interference the responders are expected to suffer due to MU-MIMO transmission is negligible or if they do not support the reciprocal MU-MIMO BF training subphase. If all of the responders are excluded from the following reciprocal MU-MIMO BF training subphase, this subphase is not present in the reciprocal MIMO phase.

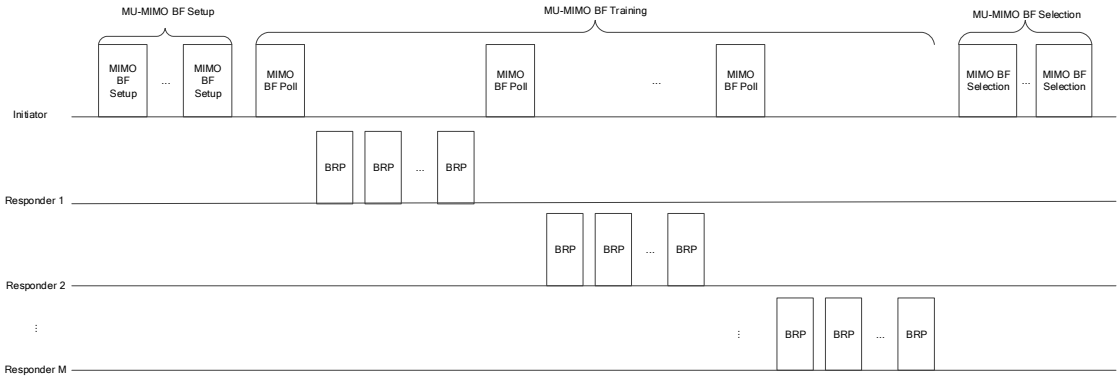

Figure 10-115—Reciprocal MIMO phase of MU-MIMO beamforming

In the MU-MIMO BF setup subphase, the initiator shall transmit one or more MIMO BF Setup frame to each responder in the MU group. The initiator should transmit the minimum number of MIMO BF Setup frames to reach all responders in the MU group. The TA field of each MIMO BF Setup frame shall be set to the BSSID of the initiator and the RA field shall be set to the broadcast address. Each MIMO BF Setup frame shall indicate a unique dialog token in the Dialog Token field for identifying MU-MIMO BF training. In the MIMO Setup Control element of each MIMO BF Setup frame, all the SU/MU, Nonreciprocal/ Reciprocal MIMO Phase and Initiator fields shall be set to 1. The EDMG group ID of the MU group shall be indicated in the EDMG Group ID field and each remaining responder shall be indicated in the Group User Mask field. For channel aggregation, the Channel Aggregation Requested subfield of the MIMO FBCK-REQ field should be set to 1. A responder whose corresponding bit in the Group User Mask field of the MIMO Setup Control element included in the received MIMO BF Setup frame is equal to 0 can ignore the subsequent MU-MIMO BF training subphase.

The initiator shall initiate an MU-MIMO BF training subphase an MBIFS following the transmission of the MIMO BF Setup frame. In the MU-MIMO BF training subphase, the initiator shall transmit a MIMO BF Poll frame to each remaining responder in the MU group. The TA field of each MIMO BF Poll frame shall be set to the BSSID of the initiator and the RA field shall be set to the MAC address of the corresponding responder. Each MIMO BF Poll frame carries the dialog token in the Dialog Token field that identifies the MU-MIMO BF training. In the MIMO Poll Control element (see 9.4.2.259) of each MIMO BF Poll frame, the SU/MU and Poll Type fields shall be set to 1. The Training Duration field shall be set to the maximum duration during which EDMG BRP-RX/TX PPDUs can be transmitted by the polled responder. Additionally, in order to reduce training time, the initiator may reduce the number of TRN subfields used for receive AWV training in the following EDMG BRP-RX/TX PPDUs transmitted by each remaining responder based on the SNRs of transmit sectors collected from each remaining responder in the SISO phase. The L-TX-RX field and the Requested EDMG TRN-Unit M field shall indicate the number of TRN subfields required for receive AWV training in the following EDMG BRP-RX/TX PPDUs to be transmitted by the corresponding responder. The Requested EDMG TRN-Unit P field shall indicate the number of TRN subfields in a TRN-Unit that need to be transmitted with the same AWV as the preamble and Data fields in the following EDMG BRP-RX/TX PPDUs to be transmitted by the corresponding responder.

A SIFS after receiving a MIMO BF Poll frame for which a remaining responder is the addressed recipient, the responder shall transmit one or more EDMG BRP-RX/TX PPDU to the initiator, where the TXVECTOR parameter EDMG_TRN_LEN is larger than zero, and the parameters RX_TRN_PER_TX_TRN, EDMG_TRN_M and EDMG_TRN_P are set to the values of the L-TX-RX field, the Requested EDMG TRN-Unit M field and the Requested EDMG TRN-Unit P field in the corresponding MIMO BF Poll frame received from the initiator, respectively. The TX Antenna Mask field of each EDMG BRP-RX/TX PPDU shall indicate the TX DMG antenna(s) that is being used by the responder to transmit the EDMG BRP-RX/

TX PPDU. The BRP CDOWN field of each EDMG BRP-RX/TX PPDU shall indicate the number of remaining EDMG BRP-RX/TX PPDUs to be transmitted by the responder.

Each MIMO BF Poll frame and each EDMG BRP-RX/TX PPDU shall be separated by SIFS.

The initiator shall initiate the MU-MIMO BF selection subphase an MBIFS following reception of the EDMG BRP-RX/TX PPDU with the BRP CDOWN field equal to 0 from the last responder in the MU group. In the MU-MIMO BF selection subphase, the initiator shall transmit one or more MIMO BF Selection frame to each responder in the MU group. The initiator should transmit the minimum number of MIMO BF Selection frames to reach all responders in the MU group. The TA field of the MIMO BF Selection frame shall be set to the BSSID of the initiator and the RA field shall be set to the broadcast address. Each MIMO BF Selection frame contains the dialog token in the Dialog Token field for identifying the MU-MIMO training. In the MIMO Selection Control element of each MIMO BF Selection frame, the MU-MIMO Transmission Configuration Type field shall be set to 1 and the Nonreciprocal MU-MIMO BF Training Based Transmission Configuration field shall not be present. The EDMG group ID corresponding to the MU group shall be indicated in the EDMG Group ID field and the number of MU-MIMO transmission configurations, N_{conf}, shall be indicated in the Number of MU-MIMO Transmission Configurations field.

Which responder(s) in the MU group is associated with each of N_{TX} TX DMG antennas for each of N_{conf} MU-MIMO transmission configurations shall be indicated in the Configuration *i* Group User Mask for Antenna *j* subfields (i = 1, 2, …, N_{conf} and j = 1, 2, …, N_{TX}) of the Reciprocal MU-MIMO BF Training Based Transmission Configuration field. The RX AWVs or RX DMG antennas of all responders associated with each of N_{TX} TX DMG antennas used in each of N_{conf} MU-MIMO transmission configurations shall be indicated in the Configuration *i* User *k* AWV feedback ID for Antenna *j* subfields, the Configuration *i* User *k* BRP CDOWN for Antenna *j* subfield and the Configuration *i* User *k* RX Antenna ID for Antenna *j* subfields (k = 1,2, …, $N_{i,j}^{(u)}$, i = 1, 2, …, N_{conf} and j = 1, 2, …, N_{TX}) of the Reciprocal MU-MIMO BF Training Based Transmission Configuration field. In more details, if User *k* in Configuration *i* participated in the reciprocal MU-MIMO BF training, the Configuration *i* User *k* AWV feedback ID for Antenna *j* subfield, the Configuration *i* User *k* BRP CDOWN for Antenna *j* subfield and the Configuration *i* User *k* RX Antenna ID for Antenna *j* subfield indicate the RX AWV of User *k* corresponding to TX DMG Antenna *j* in Configuration *i* from a receiver's perspective. Otherwise, the Configuration *i* User *k* AWV feedback ID for Antenna *j* subfield and the Configuration *i* User *k* BRP CDOWN for Antenna *j* subfield are reserved and the Configuration *i* User *k* RX Antenna ID for Antenna *j* subfield indicates the RX DMG antenna of User *k* corresponding to TX DMG Antenna *j* in Configuration *i*.

10.41.10.2.4 Hybrid beamforming for SU-MIMO and MU-MIMO

10.41.10.2.4.1 General

An EDMG STA is hybrid beamforming capable if either (or both) of the Hybrid Beamforming and SU-MIMO Supported subfield or the Hybrid Beamforming and MU-MIMO Supported subfield in the STA's EDMG Capabilities element is equal to 1. A hybrid beamforming capable STA is hybrid beamforming and SU-MIMO capable if the Hybrid Beamforming and SU-MIMO Supported subfield in the STA's EDMG Capability element is equal to 1. A hybrid beamforming capable STA is hybrid beamforming and MU-MIMO capable if the Hybrid Beamforming and MU-MIMO Supported subfield in the STA's EDMG Capability element is equal to 1. A hybrid beamforming capable STA may be hybrid beamforming and SU-MIMO capable, hybrid beamforming and MU-MIMO capable or both. A hybrid beamforming capable STA supports the hybrid beamforming protocol described in this subclause.

Hybrid beamforming is the transmission and reception of multiple spatial streams using a combination of analog beamforming (by determining appropriate AWVs) and digital beamforming (by determining appropriate spatial mapping matrices) between an SU-MIMO capable initiator and an SU-MIMO capable responder or between an MU-MIMO capable initiator and one or more MU-MIMO capable responders. The

spatial mapping matrices are determined based on the DMG antenna configuration selected as a result of the SU-MIMO or MU-MIMO beamforming protocol.

The hybrid beamforming protocol supports digital baseband training and hybrid beamforming information feedback for subsequent hybrid beamforming transmission.

The hybrid beamforming protocol can also be used to support the transmission of a single spatial stream using multiple DMG antennas with a combination of analog beamforming and digital beamforming between an SU-MIMO capable initiator and an SU-MIMO capable responder.

The AWVs of the DMG antennas may be selected using the SU-MIMO beamforming protocol (10.41.10.2.2 (SU-MIMO beamforming)) or MU-MIMO beamforming protocol (10.41.10.2.3 (MU-MIMO beamforming)), which enable the determination of the antenna configuration for the simultaneous transmission of single or multiple spatial streams from an initiator to responder(s) (or vice versa in the case of SU-MIMO).

The relationship between a transmitted signal, $\boldsymbol{x}$, and a received signal, $\boldsymbol{Y}$, in a hybrid beamforming transmission (in a flat channel or single frequency bin) can be represented as follows:

$$\boldsymbol{Y}_{i,j} = \boldsymbol{Q}_{Br,i,j}\ \boldsymbol{H}_{BB,i,j}\boldsymbol{Q}_{Bt,i}\boldsymbol{x}_i + \boldsymbol{Q}_{Br,i,j}\boldsymbol{Q}_{Ar,j}\boldsymbol{n}_{i,j}\ ;\ \boldsymbol{H}_{BB,i,j} = \boldsymbol{Q}_{Ar,j}\boldsymbol{H}_{i,j}\ \boldsymbol{Q}_{At}$$

where

$\boldsymbol{H_{i,j}}$ is the channel between the transmit DMG antennas and receive DMG antennas of the j^{th} STA in an MU-MIMO transmission

$\boldsymbol{n_{i,j}}$ is additive white noise at the receiver of the j^{th} STA in an MU-MIMO transmission

$\boldsymbol{H_{BB,i,j}}$ is the effective baseband channel at the receiver of the j^{th} STA in an MU-MIMO transmission, i.e., the channel observed by the baseband processor of the receiver when including the effect of their DMG antennas at the transmitter and receiver

$\boldsymbol{Q_{At}}$ is the $N_{TX,A} \times N_{TX}$ response of the DMG antennas of the transmitter

$\boldsymbol{Q_{Ar,j}}$ is the $N_{RX,j} \times N_{RX,j,A}$ response of the DMG antennas at the receiver of the j^{th} STA in an MU-MIMO transmission

$\boldsymbol{Q_{Bt,i}}$ is the $N_{TX} \times N_{STS}$ transmit spatial mapping matrix

$\boldsymbol{Q_{Br,i,j}}$ is the $N_{STS,j} \times N_{RX,j}$ receive equalizer at the receiver of the j^{th} STA in an MU-MIMO transmission

$\boldsymbol{x_i}$ is the transmitted SU-MIMO or MU-MIMO signal

$\boldsymbol{i}$ is the subcarrier index; for an EDMG SC mode PPDU transmission, $i = 0$; for an EDMG OFDM mode PPDU transmission, $-N_{SR} \le i \le N_{SR}$

$\boldsymbol{j}$ is index of j^{th} STA in an MU-MIMO transmission; for an SU-MIMO transmission, $j = 0$

In the hybrid beamforming protocol, the transmitter acquires hybrid beamforming information based on feedback from the receiver derived from the channel in the direction between the transmitter and receiver.

The hybrid beamforming protocol comprises the following phases:

— Announcement phase: optional if the configuration has been previously set
— Sounding phase
— Feedback phase

On completion of the hybrid beamforming protocol, a hybrid beamforming transmission may take place.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

For an EDMG SU PPDU to which hybrid beamforming is applied, $\boldsymbol{Q}_{Bt,i}$ is a transmit spatial mapping matrix and is derived from the TXVECTOR parameter EXPANSION_MAT with enumerated type NON_COMPRESSED_SV or CSI_MATRICES. For an EDMG MU PPDU to which hybrid beamforming is applied, $\boldsymbol{Q}_{Bt,i}$ is a transmit spatial mapping matrix and is derived from the TXVECTOR parameter EXPANSION_MAT with enumerated type COMPRESSED_SV. The transmit spatial mapping matrices are implementation dependent.

10.41.10.2.4.2 Announcement phase—general

The hybrid beamforming protocol announcement phase uses an announcement and optional announcement acknowledgment frame exchange to enable the initiator and responder(s) to set up their DMG antenna configurations to the desired transmit and receive antenna sectors and to indicate the start of the hybrid beamforming protocol.

If the initiator and responder are already in the correct configuration and have previously set up their hybrid beamforming protocol information, the announcement phase is optional.

The parameters governing the hybrid beamforming protocol, such as feedback type and the hybrid beamforming protocol feedback parameters, are signaled during the sounding phase.

For more specifics about the announcement phase, see 10.41.10.2.4 (Hybrid beamforming for SU-MIMO and MU-MIMO) for SU-MIMO and MU-MIMO.

10.41.10.2.4.3 Announcement phase for SU-MIMO

For SU-MIMO, the announcement and announcement acknowledgment for the hybrid beamforming protocol may use

— A Grant frame as the announcement frame and a Grant Ack frame as the announcement acknowledgment frame with a control trailer for signaling the transmission configuration to be used or

— An RTS frame as the announcement and a DMG CTS frame as the announcement acknowledgment frame with a control trailer for signaling the transmission configuration to be used.

The procedure is detailed in 10.38.12.4.3 (SU-MIMO channel access procedure).

10.41.10.2.4.4 Announcement phase for MU-MIMO

Prior to the start of hybrid beamforming training with a set of responder STAs within an MU group, the initiator shall

— Indicate the MU group within the EDMG Group ID Set element and communicate the resulting element to the STAs in the BSS (see 10.41.10.2.3 (MU-MIMO beamforming)) and

— Perform MU-MIMO beamforming with the responders of the MU group (see 10.41.10.2.3 (MU-MIMO beamforming)).

For MU-MIMO, the announcement and announcement acknowledgment for the hybrid beamforming protocol may use

— An RTS as the announcement frame and simultaneous DMG CTS frames as the announcement acknowledgment frame with a control trailer for signaling the transmission configuration or

— A DMG CTS-to-self frame as the announcement frame with a control trailer for signaling the transmission configuration.

The procedure is detailed in 10.38.12.4.4 (MU-MIMO channel access procedure).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

10.41.10.2.4.5 Sounding phase

In the sounding phase of the hybrid beamforming training protocol, the initiator (or responder) may send TRN fields to the responder (initiator) to measure the baseband channel. The TRN fields may be sent during the BRP phase (see 10.41.3 (Beam Refinement Protocol (BRP) phase)) or during the beam tracking phase (see 10.41.7 (Beam tracking)). A transmitter (initiator or responder) that desires to sound the baseband channel shall initiate initiator transmit beam refinement (see 10.41.3 (Beam Refinement Protocol (BRP) phase)) or initiator transmit beam tracking (see 10.41.7 (Beam tracking)). For more information about hybrid beamforming sounding with BRP frames, see 10.41.10.2.4 (Hybrid beamforming for SU-MIMO and MU-MIMO). For more information about hybrid beamforming sounding with tracking, see 10.41.10.2.4 (Hybrid beamforming for SU-MIMO and MU-MIMO).

The spatial mapping matrix, Q, for transmission that uses digital beamforming should be computed using the last analog combination decided between a pair of STAs (that is, on the current AWVs used by the STAs).

The transmitter shall use BRP sounding immediately after the hybrid beamforming protocol announcement or when the DMG antenna configuration or the digital beamforming feedback may need to be modified. The transmitter may use BRP or digital baseband beam tracking when DMG antenna configuration and the digital beamforming feedback are unchanged.

NOTE—The transmitter described above is the STA that sends the TRN field and can be the initiator or the responder.

For transmit beam refinement, the BRP frames indicate the TRN configuration and the type of feedback requested, and TRN fields are appended to the BRP frames to enable sounding.

For digital beam tracking, the TRN fields to enable sounding are appended to the initiator frames based on indications in the PHY header. The feedback for the digital beam tracking procedure should be the feedback negotiated in the most recent BRP sounding.

The Digital BF Request field in the EDMG BRP Request element shall be set to 1 to indicate that sounding for digital BF is requested.

For the EDMG SC mode, the DBF FBCK REQ field in the DMG Beam Refinement element shall be set to 0 to indicate MIMO channel measurement feedback, and set to 1 to indicate digital beamforming matrix feedback. For the EDMG OFDM mode, the DBF FBCK REQ field shall always be set to 1 to indicate digital beamforming matrix feedback.

For the EDMG SC mode, the number of taps requested during MIMO channel measurement or digital beamforming matrix feedback shall be set in the Number of Taps Requested field in the DMG Beam Refinement element.

10.41.10.2.4.6 Hybrid beamforming sounding with BRP frame(s)

The hybrid beamforming sounding with BRP frames is performed as follows:

a) **SU-MIMO sounding (for both initiator and responder).** The initiator shall initiate the sounding phase a SIFS following reception of the announcement acknowledgment frame (see 10.41.10.2.4 (Hybrid beamforming for SU-MIMO and MU-MIMO)) from the responder. In the initiator sounding subphase, the initiator shall transmit an EDMG BRP-TX PPDU to the responder. The EDMG BRP-TX PPDU shall include a BRP frame with an EDMG BRP Request element with the Digital BF Request field set to 1 indicating a request for performing digital beamforming, and the Feedback Type field set to 0 for SU transmission. The Nc Index field is reserved. The EDMG BRP-TX PPDU shall use the TX sector combination selected in the announcement phase in the transmission of the TRN subfield. In the EDMG BRP-TX PPDU, the TXVECTOR parameter EDMG_TRN_LEN shall be set to a value greater than 0, the parameter RX_TRN_PER_TX_TRN shall be set to 0, the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

parameter NUM_TX_CHAINS shall be set to the number of TX antennas in the TX sector combination and the parameter EDMG_TRN_M shall be set to values based on the desired configuration. The TX Antenna Mask field within the EDMG BRP-TX PPDU shall indicate the transmit DMG antenna(s) that is being used by the initiator to transmit the EDMG BRP-TX PPDU. The same AWV combination shall be maintained during the transmission of the PPDU, including the TRN field.

If the responder indicates that it is going to use SU-MIMO in the opposite direction (from the responder to the initiator) and requests hybrid beamforming training during the announcement phase, the initiator and responder shall delay sending feedback until after the responder completes the sounding phase. The responder shall initiate the responder sounding subphase a SIFS following the reception of an EDMG BRP-TX PPDU from the initiator. In the responder sounding subphase, the responder shall transmit an EDMG BRP-TX PPDU to the initiator. The EDMG BRP-TX PPDU shall include a BRP frame with an EDMG BRP Request element with the Digital BF Request field set to 1 indicating a request for performing digital beamforming, and the Feedback Type field set to 0 for SU transmission. The Nc Index field is reserved. The EDMG BRP-TX PPDU shall use the TX sector combination selected in the announcement phase in the transmission of the TRN subfield. In the EDMG BRP-TX PPDU, the TXVECTOR parameter EDMG_TRN_LEN shall be set to a value greater than 0, the parameter RX_TRN_PER_TX_TRN shall be set to 0, the parameter NUM_TX_CHAINS shall be set to the number of TX antennas in the TX sector combination and the parameter EDMG_TRN_M shall be set to values based on the desired configuration. The TX Antenna Mask field within the EDMG BRP-TX PPDU shall indicate the transmit DMG antenna(s) that is being used by the responder to transmit the EDMG BRP-TX PPDU. The same AWV combination shall be maintained during the transmission of the PPDU, including the TRN field.

In the case that only the initiator requested sounding, the responder shall not send the EDMG BRP-TX PPDU.

Figure 10-116 (Example of frame exchange sequence using SU-MIMO hybrid beamforming protocol)illustrates an example of a frame exchange sequence using the SU-MIMO hybrid beamforming protocol.

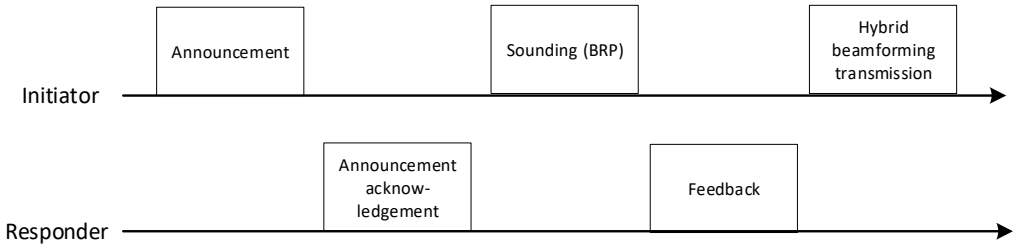

Figure 10-116—Example of frame exchange sequence using SU-MIMO hybrid beamforming protocol

b) **MU-MIMO sounding (for initiator).** The initiator shall initiate the hybrid beamforming sounding subphase a SIFS following the reception of the announcement acknowledgment frame(s) from the responder(s), if required, or immediately following the transmission of the DMG CTS-to-self frame from the initiator. In the hybrid beamforming sounding subphase, the initiator shall transmit an EDMG BRP-TX PPDU to the responders in the MU group. The EDMG BRP-TX PPDU shall include a BRP frame with an EDMG BRP Request element with the Digital BF Request field set to 1 indicating a request for performing digital beamforming, and the Feedback Type field set to 1 for MU transmission. For digital beamforming feedback in the EDMG OFDM mode, the Nc Index field is set to the number of columns, *Nc*, in the compressed beamforming feedback matrix minus 1. The RA field in the BRP frame shall be set to the broadcast address. The EDMG BRP-TX PPDU shall use the TX sector combination selected in the announcement phase in the transmission of the whole TRN subfield. In the EDMG BRP-TX PPDU, the TXVECTOR parameter

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

EDMG_TRN_LEN shall be set to a value greater than 0. The TXVECTOR parameter RX_TRN_PER_TX_TRN shall be set to 0 and the parameter EDMG_TRN_M shall be set to a value based on the desired configuration. The TX Antenna Mask field within the EDMG BRP-TX PPDU shall indicate the TX DMG antenna(s) that is being used by the initiator to transmit the EDMG BRP-TX PPDU.

10.41.10.2.4.7 Hybrid beamforming sounding with tracking

SU-MIMO tracking may take place after the establishment of a hybrid beamforming link. The combination of an announcement with BRP sounding is used to establish the antenna configuration and feedback parameters to perform tracking.

To perform tracking, the initiator shall transmit an EDMG PPDU setting up an EDMG initiator transmit beam tracking (see 10.41.7 (Beam tracking)) to the responder(s). The antenna configuration and feedback parameters used shall be based on the most recent BRP sounding parameters.

10.41.10.2.4.8 Feedback phase

The feedback phase is used by the hybrid beamforming protocol to feed back the hybrid beamforming information to the transmitter for use in a subsequent hybrid beamforming transmission.

The feedback is carried in the MIMO BF Feedback frame and its contents are as follows:

— For the EDMG SC mode, when the BRP frame used during the sounding phase has the DBF FBCK REQ field equal to 1 within the DMG Refinement element, the MIMO BF Feedback frame contains the Digital BF Feedback element carrying the digital beamforming matrix information. When DBF FBCK REQ field equal to 0, the MIMO BF Feedback frame contains the Channel Measurement Feedback element and the EDMG Channel Measurement Feedback element.

— For the EDMG OFDM mode, the MIMO BF Feedback frame contains the Digital BF Feedback element carrying the digital beamforming matrix information.

The feedback may be based on fixed grouping of the subcarriers with *Ng* = 2, 4 or 8 or the feedback may be based on dynamic grouping of the subcarriers in which the distance between the subcarriers may vary based on the characteristics of the channel fed back. In dynamic grouping, the selection of subcarriers that are fed back targets minimization of the reconstruction error at the STA receiving the feedback. These are illustrated in Figure 10-117 (Example of EDMG OFDM mode dynamic feedback).

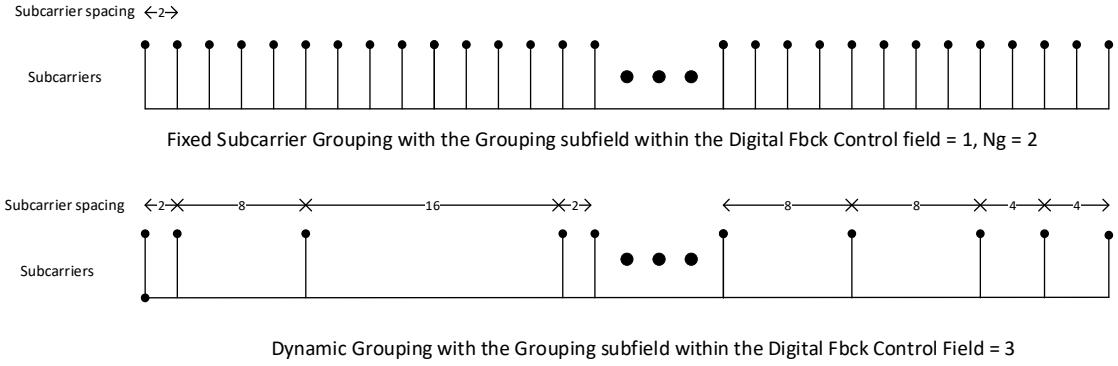

Figure 10-117—Example of EDMG OFDM mode dynamic feedback

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The capabilities governing the subcarrier grouping of an EDMG STA whose feedback is in the EDMG OFDM mode are contained in the Largest Ng Supported field and the Dynamic Grouping Supported field in the Beamforming Capability subelement of a STA's EDMG Capabilities element.

An EDMG STA shall not transmit digital BF feedback with a subcarrier grouping value larger than that in the Largest Ng Supported field indicated by the STA receiving the feedback. An EDMG STA shall not transmit digital BF feedback using dynamic grouping if the STA receiving the feedback indicates that it does not support dynamic grouping.

The SU-MIMO feedback and MU-MIMO feedback are performed as follows:

a) **SU-MIMO feedback.** If hybrid beamforming training is requested from the initiator to the responder only, the responder shall initiate the feedback phase a SIFS following the reception of an EDMG BRP-TX PPDU from the initiator with the BRP CDOWN field equal to 0.

   If hybrid beamforming training is requested from the initiator to the responder and from the responder to the initiator during the announcement phase, the initiator shall commence feedback to the responder a SIFS following the reception of an EDMG BRP-TX PPDU from the initiator with the BRP CDOWN field equal to 0. The responder shall then commence feedback to the initiator a SIFS following the reception of the feedback from the initiator.

   An exemplary procedure is shown in Figure 10-118 (Example of frame exchange sequence using SU-MIMO hybrid beamforming protocol).

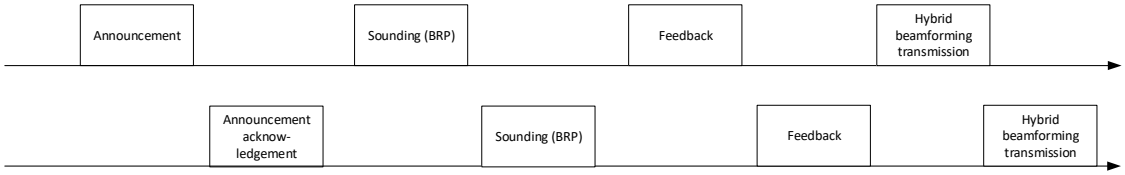

Figure 10-118—Example of frame exchange sequence using SU-MIMO hybrid beamforming protocol

b) **MU-MIMO feedback.** The initiator shall initiate the MU-MIMO beamforming feedback subphase an MBIFS following the transmission of an EDMG BRP-TX PPDU with the BRP CDOWN field set to 0. In the MU-MIMO beamforming feedback subphase, the initiator shall transmit a MIMO BF Poll frame to poll each remaining responder to collect hybrid beamforming MU-MIMO feedback from the preceding MU-MIMO sounding subphase. The TA field of each MIMO BF Poll frame shall be set to the MAC address of the initiator and the RA field shall be set to the MAC address of the corresponding responder. Each MIMO BF Poll frame carries the dialog token in the Dialog Token field that identifies the MU-MIMO BF sounding. In the MIMO Poll Control element of each MIMO BF Poll frame, the SU/MU field shall be set to 1 and the Poll Type field shall be set to 0.

   A SIFS after receiving a MIMO BF Poll frame for which a responder is the addressed recipient, the responder shall transmit a MIMO BF Feedback frame which contains a Digital BF Feedback element to the initiator. The RA field of the MIMO BF Feedback frame shall be set to the MAC address of the initiator and the TA field shall be set to the MAC address of the responder. The MIMO BF Feedback frame carries the dialog token in the Dialog Token field that identifies the MU-MIMO sounding. In the MIMO Feedback Control element of the MIMO BF Feedback frame, the SU/MU field shall be set to 1 and the Link Type field shall be set to 0. If the MIMO BF Feedback frame contains a Digital BF Feedback element, the ComeBack Delay field shall be set to 0. Otherwise, the ComeBack Delay field shall be set to a nonzero value that indicates when the responder is ready with the Digital BF Feedback. If the ComeBack Delay field is 0 and for a 2.16+2.16 GHz or 4.32+4.32 GHz channel, the Channel Aggregation Present subfield of the MIMO FBCK-TYPE field shall be set to 1. If the ComeBack Delay field is a nonzero value, the Channel Aggregation Present subfield of the MIMO FBCK-TYPE field shall be set to 0.

An exemplary procedure is shown in Figure 10-119 (Example of frame exchange sequence using MU-MIMO hybrid beamforming protocol).

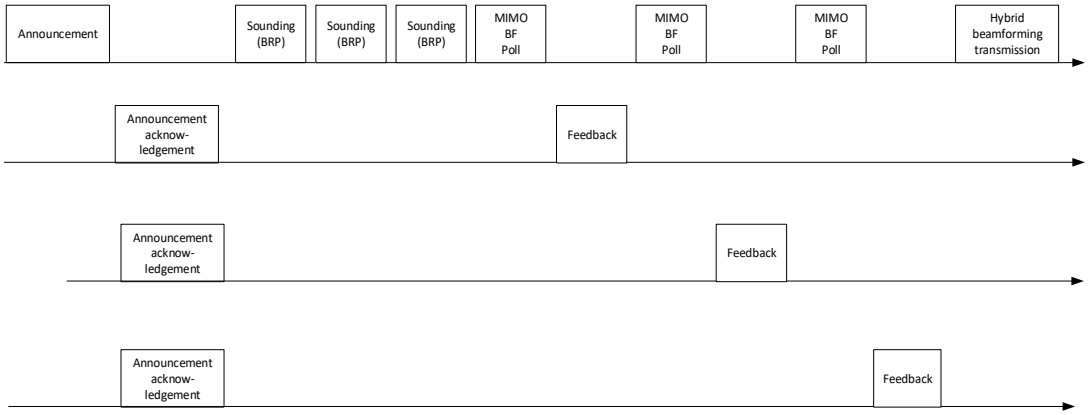

Figure 10-119—Example of frame exchange sequence using MU-MIMO hybrid beamforming protocol

10.41.10.3 Beamforming for asymmetric links

10.41.10.3.1 General

)For the purposes of EDMG operation, an asymmetric link is present between a pair of STAs when in one STA the difference between the maximum receive antenna gain and the quasi-omni receive antenna gain is higher than 15 dB, while for the other STA this difference is at most 15 dB.

NOTE—As specified in 20.9.1 (Beamforming concept), 15 dB is the sensitivity difference between the DMG control mode and the DMG SC mode for a PHY data rate greater than 1 Gb/s. When the difference between the full gain receive antenna setting and the quasi-omni receive antenna setting is higher than 15 dB, a STA might be able to receive a PPDU at full gain using the DMG SC mode at a range higher than in a quasi-antenna receive setting using the DMG control mode when the same antenna setting is used by the STA that transmits the PPDU.

The procedure defined in this subclause enables an initiator and a responder that would otherwise have an asymmetric link if a quasi-omni antenna configuration were to be used for communication between them, to perform beamforming according to the procedure described in this subclause. Following the successful establishment of the beamformed link, all frame exchange sequences between the STAs take place using the established beamformed link. STAs may determine whether to perform asymmetric beamforming according to the "Near-Far" self classification described in 10.38.12.6 ("Near-Far" self classification).

The procedure defined in this subclause requires that the DMG Antenna Reciprocity and Antenna Pattern Reciprocity subfields within the DMG STA Capability Information field of the initiator and responder are both set to 1.

10.41.10.3.2 Scheduling during the BTI

To enable beamforming for asymmetric links, a PCP or AP shall

— In the PPDU containing a DMG Beacon frame transmitted in a BTI through the sector for which the asymmetric beamforming training is considered to be performed, include TRN-R subfields within the TRN field of the PPDU as specified in 10.41.4 (Beamforming in BTI).

— Include an EDMG Extended Schedule element in each DMG Beacon frame that is transmitted in the step above. The EDMG Extended Schedule element shall include at least one allocation that has the Asymmetric Beamforming Training subfield for the allocation set to 1. The duration of this allocation shall be at least

Copyright © 2025 IEEE. All rights reserved.

$N_{STS} \times aSTSTime + MBIFS + aAirPropagationTime + TXTIME(Sector\ Ack)$

where

N_{STS}	is the value of the Number of Space-time Slots subfield in the EDMG Extended Schedule element describing this allocation.
aSTSTime	is the duration a space-time slot defined in 10.41.10.3.3 (Beamforming training allocation in DTI).
TXTIME(*Sector Ack*)	is the transmission time of a Sector Ack frame, assuming there are N_{STS} Sector Ack subfields in the Sector Ack frame.

A PCP or AP shall not include in a DMG Beacon frame an EDMG Extended Schedule element including an allocation that has the Asymmetric Beamforming Training subfield for the allocation equal to 1 without inserting TRN-R subfields in the TRN field of the PPDU containing the DMG Beacon.

A non-PCP and non-AP STA receiving a DMG Beacon frame with appended TRN-R fields and that executes the beamforming procedure described in this subclause shall use the TRN-R fields to perform receive beamforming as specified in 10.41.2 (Sector-level sweep (SLS) phase). The STA may then use one or more of the allocations announced in the EDMG Extended Schedule element that have the Asymmetric Beamforming Training subfield equal to 1 (see 9.4.2.266) to perform the procedure specified in 10.41.10.3.3 (Beamforming training allocation in DTI). The STA should select the asymmetric beamforming allocation which corresponds to the DMG Beacon frame received with the best quality in the BTI. The determination of which DMG Beacon frame was received with the best quality is implementation dependent.

10.41.10.3.3 Beamforming training allocation in DTI

A beamforming training allocation in the DTI is scheduled through the EDMG Extended Schedule element. A beamforming training allocation has the Asymmetric Beamforming Training subfield for the allocation equal to 1. Channel access during a beamforming training allocation is as follows:

— The PCP or AP (i.e., the initiator) shall listen on the combination of sector and DMG antenna that was used for transmission of the DMG Beacon frame describing this allocation during the last BTI. The PCP or AP shall listen for N_{STS} space-time slots for any responder's transmission, where N_{STS} is the value of the Number of Space-time Slots subfield describing the allocation. A space-time slot has a duration of aAirPropagationTime + TXTIME(SSW) + aSIFSTime, where aAirPropagationTime accounts for the propagation delay between the initiator and the responder.

— At the start of the allocation, the responder(s) shall invoke a random backoff procedure to transmit an SSW frame. The random backoff procedure begins at the start of the beamforming training allocation with the responder selecting a backoff count as a random integer drawn from a uniform distribution [0, N_{STS}), i.e., 0 to $N_{STS} - 1$. The responder shall decrement the backoff count by one at the end of each space-time slot, even if the CS function at the responder indicates the medium busy condition for that space-time slot. The responder may transmit the SSW frame only at the start of the space-time slot for which the backoff count is 0 at the beginning of the space-time slot. The responder's transmission is performed in directional mode using a transmit DMG antenna and sector corresponding to the receive DMG antenna and sector trained by the TRN-R subfields received in the last BTI.

— A responder may transmit more than one consecutive SSW frame within one beamforming training allocation, but shall not exceed the maximum number of space-time slots a responder can occupy as given by $2^{Nmax\ STS}$, where *Nmax STS* is the value of the Nmax STS subfield describing the allocation.

— After transmitting the SSW frame(s), the responder switches to directional receive in the sector trained by TRN-R in the last BTI.

— MBIFS after the PCP or AP completes listening for N_{STS} space-time slots, the initiator shall transmit a Sector Ack frame on the same combination of sector and DMG antenna that was used for listening.

The Sector Ack frame contains the information about the STAs that have been identified during the allocation. In case several SSW frames have been received from a STA, the Sector Ack refers to the SSW frame that was received with the best quality. The determination of which frame was received with the best quality is implementation dependent.

— A responder that transmits an SSW frame during a beamforming training allocation, but that does not receive a Sector Ack frame in response, may repeat the attempt to perform asymmetric beamforming training during the next beamforming training allocation.

An example of beamforming training for asymmetric links of three EDMG STAs and an EDMG PCP or EDMG AP is shown in Figure 10-120 (Example of beamforming training for asymmetric links in beamforming training allocation). In the example, the AP or PCP allocates a dedicated SP to perform the asymmetric beamforming training, which consists of sequential listening on each sector, followed by the Sector Ack transmissions by the PCP or AP. STA#1 selects the second (out of four) space-time slot and transmits the SSW frame with a beamforming link determined by the TRN-R appended during the last BTI. STAs #2 and #3 choose the same third space-time slot and transmit SSW frames, which results in a collision. MBIFS after the fourth space-time slot, the AP transmits a Sector Ack frame that includes information about all STAs from which SSW frames were received: STA#1 and either one of STAs #2 or #3 or none of them. If after the reception of the Sector Ack frame a STA cannot find itself in the list of identified STAs, it may retry to perform asymmetric beamforming training during the next beamforming training allocation for this sector. A STA can attempt to receive the Sector Ack frame using either a directional or a quasi-omni antenna pattern.

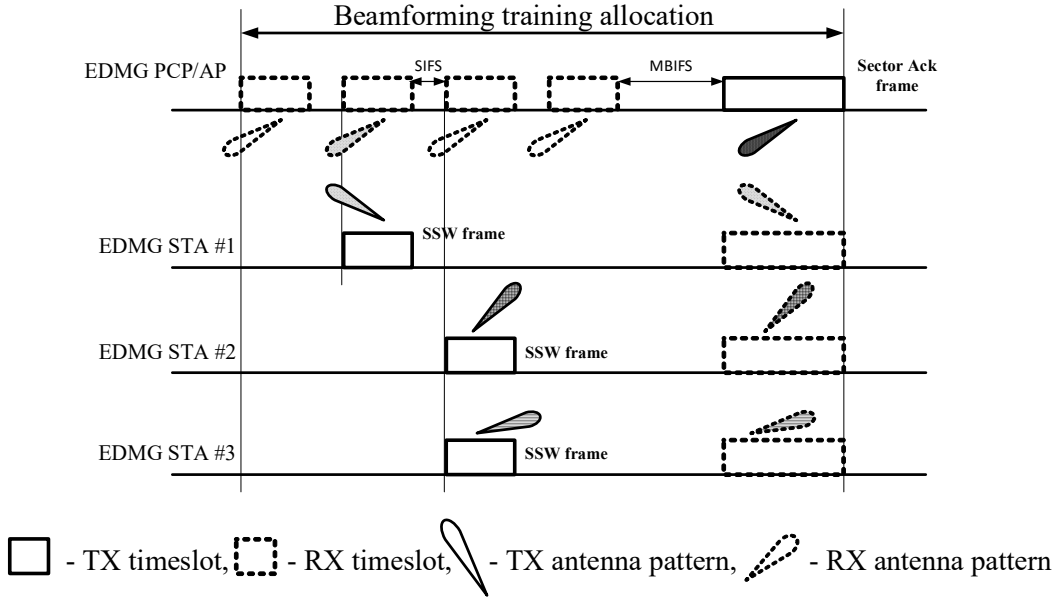

Figure 10-120—Example of beamforming training for asymmetric links in beamforming training allocation

Following the successful completion of the beamforming training, the AP or PCP can schedule directional allocations for data exchange with the non-PCP and non-AP STA (see 10.38.12.3 (Directional allocation)).

10.41.10.4 Group beamforming

An initiator that is an AP or PCP may simultaneously train a group of responder STAs that have antenna pattern reciprocity. This is referred to as group beamforming and, if performed, takes place in the BTI of a beacon interval. In group beamforming, the initiator trains its transmit antennas and sectors while a group of

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

responders train their receive antennas and sectors. A DMG STA supports antenna pattern reciprocity if the value of the Antenna Pattern Reciprocity field in the STA's DMG Capabilities element is 1.

To perform group beamforming, an AP or PCP shall, as specified in 10.41.4 (Beamforming in BTI), include TRN-R subfields within the TRN field of each PPDU containing a DMG Beacon frame transmitted in a BTI. This is done by

— Setting the TXVECTOR parameter EDMG_TRN_LEN to a value greater than 0. The value of this parameter should be based on the maximum number of receive sectors and antennas across all intended responders; and
— Setting the TXVECTOR parameter EDMG_PPDU_TYPE to EDMG-TRN-R.

If the number of TRN-R subfield is smaller than a responder(s)' receive sectors and antennas, the responder(s) may train selected receive sectors and antennas with the available TRN-R subfields and may continue to train the other receive sectors and antennas with a subsequent DMG Beacon frame transmitted by the same transmit sector and with TRN-R subfields appended. Through reception of these TRN-R subfields, responders can determine the initiator's transmit antenna(s) and sector(s) that were received with the best quality and, given antenna pattern reciprocity, the responders can also determine their corresponding transmit antenna(s) and sector(s) with the best quality.

If the responder detects a change in the initiator's best TX antenna and sector, the responder may inform the AP or PCP of the change by transmitting an unsolicited Information Response frame to the AP or PCP containing an EDMG Channel Measurement Feedback element with an updated list of antenna and sector pairs.

10.41.10.5 BRP transmit sector sweep (BRP TXSS)

10.41.10.5.1 General

Beam refinement protocol transmit sector sweep (BRP TXSS) is a procedure that allows EDMG STAs to determine improved antenna configurations for transmission and reception. The procedure is performed with the use of BRP frames, and consists of various phases of transmit sector sweep and receive training.

In BRP TXSS, the STA that initiates the procedure through the transmission of a BRP frame is referred to as the initiator, and the recipient STA of the BRP frame that participates in a BRP TXSS with the initiator is referred to as the responder.

In the BRP TXSS procedure, a BRP frame with acknowledgment is defined as a BRP frame that has the TX-TRN-OK field within the DMG Beam refinement element set to 1.

BRP TXSS may include as many as six phases: setup phase, transmit training phase by the initiator with feedback (referred to as Initiator BRP TXSS), receive training phase of the responder, transmit training phase by the responder with feedback (referred to as Responder BRP TXSS), receive training phase of the initiator, and acknowledgment phase. A BRP TXSS shall include a setup phase, an Initiator BRP TXSS, and an acknowledgment phase. As defined in 10.41.10.5.2 (BRP TXSS configuration), receive training for responder, Responder BRP TXSS, and receive training for initiator are included in a BRP TXSS depending on whether the procedure is a SISO BRP TXSS or a MIMO BRP TXSS and, for a SISO BRP TXSS, on reciprocity characteristics of the initiator and the responder.

An example of BRP TXSS is shown in Figure 10-121 (BRP TXSS when comprising all six phases) for the case when the procedure is comprised of all six phases. In Figure 10-121 (BRP TXSS when comprising all six phases) and in the remainder of 10.41.10.5 (BRP transmit sector sweep (BRP TXSS)):

— N_{init} is the value of the TXSS-PPDUs subfield within the EDMG BRP Request element in the BRP frame sent by the initiator to start the BRP TXSS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— R_{init} is the value of the TXSS-REPEAT subfield within the EDMG BRP Request element in the BRP frame sent by the initiator to start the BRP TXSS.
— N_{resp} is the value of the TXSS-PPDUs subfield within the EDMG BRP Request element in the BRP frame sent by the responder to confirm the procedure.
— Rresp is the value of the TXSS-REPEAT subfield within the EDMG BRP Request element in the BRP frame sent by the responder to confirm the procedure.

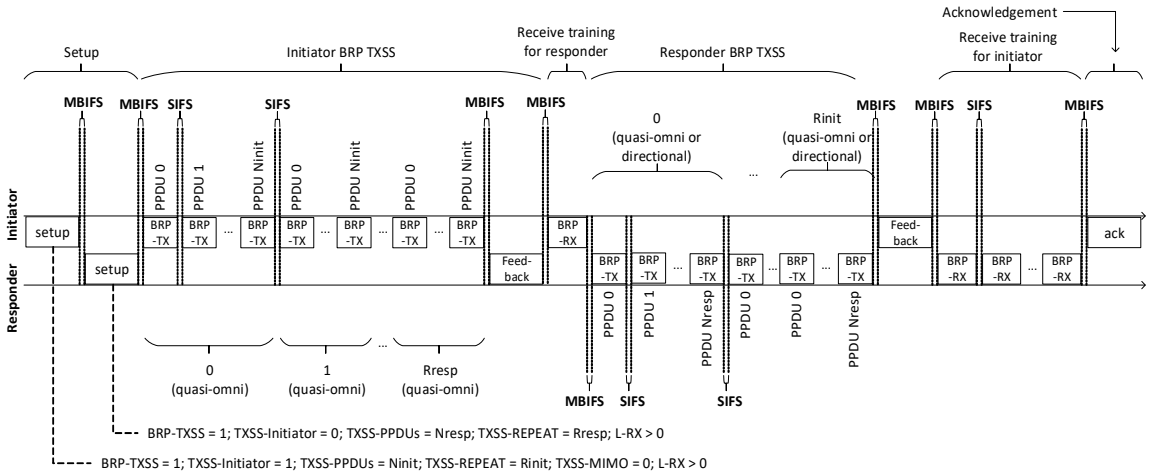

Figure 10-121—BRP TXSS when comprising all six phases

As shown in Figure 10-121 (BRP TXSS when comprising all six phases) and as defined in 10.41.10.5.3 (BRP TXSS execution), the setup phase consists of the transmission of a BRP frame that requests BRP TXSS by the initiator followed by the transmission of a BRP frame that confirms the procedure by the responder. After receiving confirmation of the BRP TXSS request from the responder, the initiator performs an Initiator BRP TXSS. As defined in 10.41.10.5.2 (BRP TXSS configuration), in an Initiator BRP TXSS the initiator transmits N_{init} + 1 EDMG BRP-TX PPDUs consecutively R_{resp} + 1 times, and the same DMG antenna or set of DMG antennas is used by the responder when receiving the TRN field of all N_{init} + 1 EDMG BRP-TX PPDUs within one of the R_{resp} + 1 repetitions. The feedback sent by the responder within the Initiator BRP TXSS consists of a BRP frame with feedback of the measurements it performed during the reception of EDMG BRP-TX PPDUs. If receive training of the responder is included in the procedure, the TRN field of the EDMG BRP-RX PPDU sent immediately after the Initiator BRP TXSS is transmitted by the initiator and received by the responder using antenna configurations determined in the preceding Initiator BRP TXSS. In a Responder BRP TXSS, if present, the responder transmits N_{resp} + 1 EDMG BRP-TX PPDUs consecutively R_{init} + 1 times, and the same DMG antenna or set of DMG antennas is used by the initiator when receiving the TRN field of all N_{resp} +1 EDMG BRP-TX PPDUs within one of the R_{init} +1 repetitions. The feedback sent by the initiator within the Responder BRP TXSS consists of a BRP frame with feedback of the measurements it performed during the reception of EDMG BRP-TX PPDUs transmitted by the responder. If receive training of the initiator is included in the procedure, the TRN field of the one or more EDMG BRP-RX PPDUs sent immediately after the Responder BRP TXSS are transmitted by the responder and received by the initiator using antenna configurations determined in the preceding phases of the procedure. As defined in 10.41.10.5.2 (BRP TXSS configuration), the number of EDMG BRP-RX PPDUs transmitted in the receive training of the initiator depends on reciprocity characteristics of the initiator and the responder. The BRP TXSS is concluded with the transmission of a BRP frame with acknowledgment.

The TRN field of EDMG BRP-TX and EDMG BRP-RX PPDUs sent in a BRP TXSS may be transmitted with different DMG antennas than the ones used in the setup phase. Also, the TRN field of EDMG BRP-TX

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

and EDMG BRP-RX PPDUs used in the procedure may be received with DMG antennas that are not the same ones used in the setup phase.

If both initiator and responder of a BRP TXSS are SU-MIMO capable (as defined in 10.41.10.2.2 (SU-MIMO beamforming)), EDMG BRP-TX PPDUs used in a BRP TXSS may be sent using multiple transmit chains simultaneously. As described in 10.41.10.2.2 (SU-MIMO beamforming), the procedure in this case corresponds to the SISO phase of SU-MIMO beamforming training, and the MIMO phase of SU-MIMO beamforming training shall be performed after completion of the BRP TXSS.

As defined in 28.9.2.2.2 (EDMG BRP PPDU structure), the TRN field in EDMG BRP PPDUs sent as part of BRP TXSS is transmitted over the entire channel bandwidth. Therefore, the BRP TXSS allows for transmit sector sweep over the entire channel bandwidth when the initiator and responder operate on a 4.32 GHz, 6.48 GHz, 8.64 GHz, 2.16+2.16 GHz, or 4.32+4.32 GHz channel.

Similar to as specified in 10.41.6.4.2 (Beam refinement transaction), all the PPDUs in a BRP-TXSS are transmitted with the same TXVECTOR parameters CH_BANDWIDTH and CHANNEL_AGGREGATION values as those of the PPDU that initiated the BRP-TXSS.

10.41.10.5.2 BRP TXSS configuration

10.41.10.5.2.1 General

A SISO BRP TXSS is a BRP TXSS in which EDMG BRP PPDUs used in the procedure are transmitted using a single transmit chain. A MIMO BRP TXSS is a BRP TXSS in which EDMG BRP PPDUs used in the procedure are transmitted using multiple transmit chains.

10.41.10.5.2.2 SISO BRP TXSS configuration—general

BRP frames transmitted in a BRP TXSS with feedback within an Initiator BRP TXSS or a Responder BRP TXSS and with acknowledgment at the end of the procedure shall be transmitted and received with the same DMG antennas and AWVs used in the setup phase. Also, these frames shall not include a TRN field.

All fields except for the TRN field of EDMG BRP-TX and EDMG BRP-RX PPDUs used in SISO BRP TXSS shall be transmitted with the same DMG antenna and AWV used in the setup phase. The TRN field of EDMG BRP-TX and EDMG BRP-RX PPDUs used in SISO BRP TXSS may be transmitted with a different DMG antenna than the one used in the transmission of the remaining fields of the same PPDU.

All fields of EDMG BRP-TX and EDMG BRP-RX PPDUs used in SISO BRP TXSS except for the TRN field shall be received with the same DMG antenna and AWV used in the setup phase. The TRN field of EDMG BRP-TX and EDMG BRP-RX PPDUs used in SISO BRP TXSS may be received with a DMG antenna that is not the same one used in the reception of the remaining fields of the same PPDU.

The Initiator BRP TXSS shall consist of the transmission of N_{init} + 1 EDMG BRP-TX PPDUs consecutively repeated R_{resp} + 1 times by the initiator followed by the transmission of a BRP frame with feedback by the responder. The EDMG BRP-TX PPDUs transmitted in an Initiator BRP TXSS shall be configured as follows:

— The TXVECTOR parameter TRN_RX_PATTERN of the PPDU shall be set to QUASI_OMNI.
— The TXVECTOR of the i^{th} EDMG BRP-TX PPDU within each of the R_{resp} + 1 repetitions, where $1 \leq i \leq N_{init} + 1$, shall have the same value for the parameters EDMG_TRN_LEN, EDMG_TRN_P, EDMG_TRN_M, and EDMG_TRN_N.
— The TRN field of the i^{th} EDMG BRP-TX PPDU within each of the R_{resp} + 1 repetitions, where $1 \leq i \leq N_{init} + 1$, shall be transmitted using the same DMG antenna.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The j^{th} TRN subfield of the k^{th} TRN-Unit of the i^{th} EDMG BRP-TX PPDU within each of the R_{resp} + 1 repetitions, where $1 \le j \le M + 1$, $2 \le k \le L + 1$, and $1 \le i \le N_{init} + 1$, where M and L are the values of the TXVECTOR parameters EDMG_TRN_M and EDMG_TRN_LEN, shall be transmitted using the same AWV.
— The initiator should transmit the TRN field of each of the N_{init} + 1 EDMG BRP-TX PPDUs within one of the R_{resp} + 1 repetitions in an Initiator BRP TXSS using a different DMG antenna.

Similarly, the Responder BRP TXSS, if present, shall consist of the transmission of N_{resp} +1 EDMG BRP-TX PPDUs consecutively repeated R_{init} + 1 times by the responder followed by the transmission of a BRP frame with feedback by the initiator. The EDMG BRP-TX PPDUs transmitted in a Responder BRP TXSS shall be configured as follows:

— The value of the TXVECTOR parameter TRN_RX_PATTERN shall be set according to the Antenna Pattern Reciprocity and the DMG Antenna Reciprocity subfields within the DMG STA Capability Information field of both initiator and responder, as defined in 10.41.10.5.2 (BRP TXSS configuration).
— The TXVECTOR of the i^{th} EDMG BRP-TX PPDU within each of the R_{init} + 1 repetitions, where $1 \le i \le N_{resp} + 1$, shall have the same value for the parameters EDMG_TRN_LEN, EDMG_TRN_P, EDMG_TRN_M, and EDMG_TRN_N.
— The TRN field of the i^{th} EDMG BRP-TX PPDU within each of the R_{init} + 1 repetitions, where $1 \le i \le N_{resp} + 1$, shall be transmitted using the same DMG antenna.
— The j^{th} TRN subfield of the k^{th} TRN-Unit of the i^{th} EDMG BRP-TX PPDU within each of the R_{init} + 1 repetitions, where $1 \le j \le M + 1$, $2 \le k \le L + 1$, and $1 \le i \le N_{resp} + 1$, where M and L are the values of the TXVECTOR parameters EDMG_TRN_M and EDMG_TRN_LEN, respectively, shall be transmitted using the same AWV.
— The responder should transmit the TRN field of each of the N_{resp} + 1 EDMG BRP-TX PPDUs within one of the R_{init} + 1 repetitions in a Responder BRP TXSS using a different DMG antenna.

Receive training of the responder after the Initiator BRP TXSS is mandatory in SISO BRP TXSS, and it consists of the transmission of one EDMG BRP-RX PPDU by the initiator that allows for the responder to determine its receive configuration for the transmit configuration determined in the preceding Initiator BRP TXSS. The TRN field of the EDMG BRP-RX PPDU used for receive training of the responder

— Shall be transmitted with the best AWV identified in the preceding Initiator BRP TXSS.
— Shall be received with the DMG antenna corresponding to the best AWV configuration identified in the preceding Initiator BRP TXSS.
— Shall have a length that shall be equal to the value of the L-RX field in the BRP frame sent by the responder to confirm the procedure plus one.

Receive training of the initiator shall be performed if the value of the L-RX field in the BRP frame sent by the initiator to start the BRP TXSS is greater than 0. If the L-RX field in the BRP frame sent to start the BRP TXSS is equal to 0, receive training of the initiator shall not be performed. Receive training of the initiator consists of the transmission of one or more EDMG BRP-RX PPDUs by the responder that allows for the initiator to determine its receive configuration for the transmit configuration determined in the preceding Responder BRP TXSS or in the preceding receive training of the responder. The TRN field of the EDMG BRP-RX PPDUs used for receive training of the initiator

— Shall be transmitted with the best AWV identified in the preceding Responder BRP TXSS or in the receive training of the responder, as defined in 10.41.10.5.2 (BRP TXSS configuration).
— Shall be received with the DMG antenna corresponding to the best AWV identified in the Responder BRP TXSS or in the Initiator BRP TXSS, or with multiple DMG antennas, as defined in 10.41.10.5.2 (BRP TXSS configuration).
— Shall have a length that shall be equal to the value of the L-RX field in the BRP frame sent by the initiator to start the procedure plus one.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An example of a BRP TXSS is shown in Figure 10-122 (Example of BRP TXSS: responder performs measurements using one DMG antenna) for a scenario in which the initiator and the responder have two DMG antennas, and both the initiator and responder use one DMG antenna when performing measurements. It is assumed in this example that the best AWV configuration identified in the Initiator BRP TXSS was obtained when the initiator used DMG antenna 0 and the responder used DMG antenna 1, and that the best AWV configuration identified in the Responder BRP TXSS was obtained when the responder used DMG antenna 0 and the initiator used DMG antenna 0. If the responder in this example was capable of processing all of its antennas simultaneously, the duration of the BRP TXSS could be shortened as shown in Figure 10-123 (Example of BRP TXSS: responder performs measurements using multiple DMG antennas simultaneously).

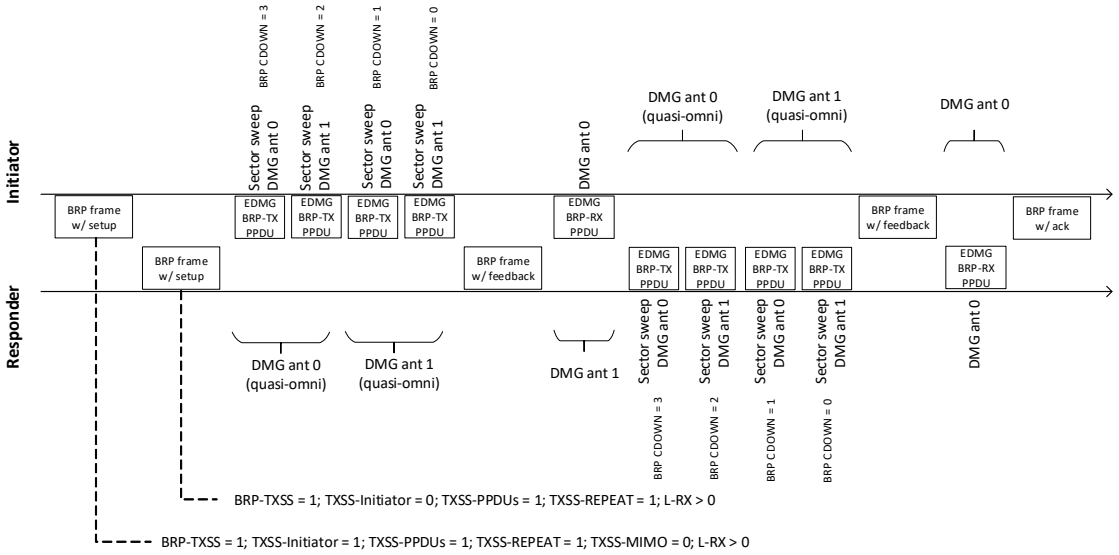

Figure 10-122—Example of BRP TXSS: responder performs measurements using one DMG antenna

The first TRN-Unit in an EDMG BRP PPDU used in a SISO BRP TXSS may be used for the initiator and responder to switch DMG antennas and shall not be processed by the receiver. Therefore, for EDMG BRP-TX and EDMG BRP-RX PPDUs transmitted during SISO BRP TXSS, the value of the TXVECTOR parameter EDMG_TRN_LEN shall be set to $k + 1$, where

— For the EDMG BRP-RX PPDU sent in the receive training for the responder, k is equal to the value of the L-RX field in the BRP frame sent by the responder to confirm the procedure.

— If present, for the one or more EDMG BRP-RX PPDUs sent in the receive training for the initiator, k is equal to the value of the L-RX field in the BRP frame sent by the initiator to start the BRP TXSS.

The TRN subfields that comprise the first TRN-Unit in EDMG BRP-TX PPDUs used as part of a BRP TXSS shall not be included in the TRN subfield and AWV feedback ID indexing procedures described in 28.9.2.2.5 (TRN field definition).

When transmitting an EDMG BRP-TX or an EDMG BRP-RX PPDU as part of a SISO BRP TXSS, an EDMG STA may change the DMG antenna used in the transmission of its TRN field during the first TRN-Unit and shall not change DMG antenna during the remaining TRN-Units.

When receiving an EDMG BRP-TX or an EDMG BRP-RX PPDU as part of SISO BRP TXSS, an EDMG STA may change the DMG antenna used in the reception of the TRN field during the first TRN-Unit and shall not change DMG antenna during the remaining TRN-Units.

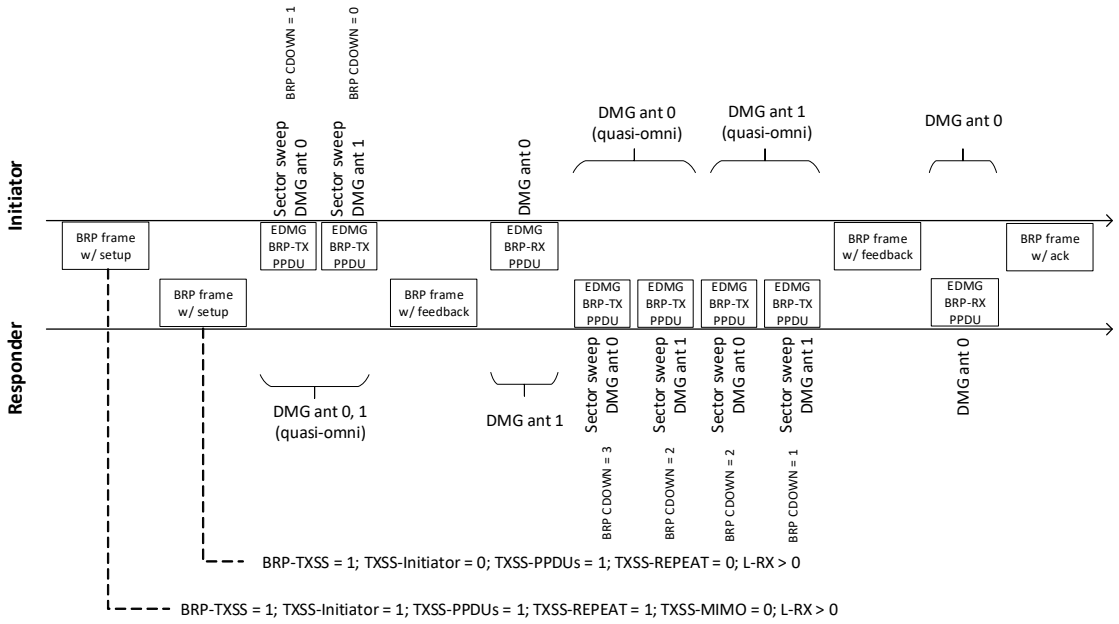

Figure 10-123—Example of BRP TXSS: responder performs measurements using multiple DMG antennas simultaneously

For EDMG BRP-TX PPDUs used in a BRP TXSS, the AWV used in the transmission of the first *P* TRN subfields of each TRN-Unit depends on whether the DMG antenna used in the transmission of an EDMG BRP-TX PPDU changes at the beginning of the TRN field. As defined in 28.9.2.2.5 (TRN field definition), if the TRN field of an EDMG BRP-TX PPDU is transmitted with the same DMG antenna as the remaining fields of the PPDU, the first *P* TRN subfields of each TRN-Unit shall be transmitted using the same AWV as the remaining fields of the PPDU. If the DMG antenna used in the transmission of an EDMG BRP-TX PPDU changes at the beginning of the TRN field, the AWV used in the transmission of the first *P* TRN subfields of each TRN-Unit is selected in an implementation dependent manner and should be the same for all TRN-Units.

10.41.10.5.2.3 SISO BRP TXSS configuration—with reciprocity

A STA, responder or initiator, is antenna pattern reciprocal if the Antenna Pattern Reciprocity subfield in the DMG STA Capability Information field of the STA's DMG Capabilities element is 1. Otherwise, the STA is not antenna pattern reciprocal.

A STA, responder or initiator, is DMG antenna reciprocal if the DMG Antenna Reciprocity subfield in the DMG STA Capability Information field of the STA's DMG Capabilities element is 1. Otherwise, the STA is not DMG antenna reciprocal.

Responder BRP TXSS and receive training for the initiator are included in a SISO BRP TXSS depending on the reciprocity characteristics of the initiator and responder (see 10.41.10.5.2 (BRP TXSS configuration)). Specifically, each of these two phases shall or shall not be included in a SISO BRP TXSS as defined in Table 10-38.

If a SISO BRP TXSS includes receive training for the initiator, the L-RX field in the EDMG BRP Request element or EDMG BRP field within the BRP frame sent by the initiator to start the BRP TXSS shall be set to a value greater than 0. If a SISO BRP TXSS does not include receive training for the initiator, the L-RX field

Table 10-38—Definition of whether Responder BRP TXSS and receive training for initiator are included in a SISO BRP TXSS

("Yes" defines that the phase shall be included, and "No" defines that the phase shall not be included)

Initiator	Responder	Phase: Responder BRP TXSS	Phase: Receive training for the initiator
Antenna pattern reciprocal	Antenna pattern reciprocal	No	No
Antenna pattern reciprocal	DMG antenna reciprocal	Yes	No
Antenna pattern reciprocal	Not antenna pattern reciprocal and not DMG antenna reciprocal	Yes	Yes
DMG antenna reciprocal	Antenna pattern reciprocal	No	Yes
DMG antenna reciprocal	DMG antenna reciprocal	Yes	Yes
DMG antenna reciprocal	Not antenna pattern reciprocal and not DMG antenna reciprocal	Yes	Yes
Not antenna pattern reciprocal and not DMG antenna reciprocal	Antenna pattern reciprocal	No	Yes
Not antenna pattern reciprocal and not DMG antenna reciprocal	DMG antenna reciprocal	Yes	Yes
Not antenna pattern reciprocal and not DMG antenna reciprocal	Not antenna pattern reciprocal and not DMG antenna reciprocal	Yes	Yes

in the EDMG BRP Request element or EDMG BRP field within the BRP frame sent by the initiator to start the BRP TXSS shall be set to 0.

If the initiator is antenna pattern reciprocal and the responder is DMG antenna reciprocal, then

— The TXSS-REPEAT field in the EDMG BRP Request element or EDMG BRP field within the BRP frame sent by the initiator to start the BRP TXSS shall be set to 0.

— The TXVECTOR parameter TRN_RX_PATTERN of EDMG BRP-TX PPDUs used in the Responder BRP TXSS shall be set to DIRECTIONAL.

— The TRN field of the EDMG BRP-TX PPDUs used in the Responder BRP TXSS shall be received with the RX AWV configuration corresponding to the best AWV configuration identified in the Initiator BRP TXSS.

If the initiator is antenna pattern reciprocal and the responder is not antenna pattern reciprocal and is not DMG antenna reciprocal, then

— The TXSS-REPEAT field in the EDMG BRP Request element or EDMG BRP field within the BRP frame sent by the initiator to start the BRP TXSS shall be set to 0.

— The TXVECTOR parameter TRN_RX_PATTERN of EDMG BRP-TX PPDUs used in the Responder BRP TXSS shall be set to QUASI_OMNI.

— The TRN field of the EDMG BRP-TX PPDUs used in the Responder BRP TXSS shall be received with the DMG antenna corresponding to the best AWV configuration identified in the Initiator BRP TXSS.

If the initiator is DMG antenna reciprocal and the SISO BRP TXSS includes a Responder BRP TXSS, then

— The TXSS-REPEAT field in the EDMG BRP Request element or EDMG BRP field within the BRP frame sent by the initiator to start the BRP TXSS shall be set to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The TXVECTOR parameter TRN_RX_PATTERN of EDMG BRP-TX PPDUs used in the Responder BRP TXSS shall be set to QUASI_OMNI.
— The TRN field of the EDMG BRP-TX PPDUs used in the Responder BRP TXSS shall be received with the DMG antenna corresponding to the best AWV configuration identified in the Initiator BRP TXSS.

If the initiator is not antenna pattern reciprocal and is not DMG antenna reciprocal and the SISO BRP TXSS includes a Responder BRP TXSS, then

— The TXSS-REPEAT field in the EDMG BRP Request element or EDMG BRP field within the BRP frame sent by the initiator to start the BRP TXSS may be set to a value greater than 0.
— The TXVECTOR parameter TRN_RX_PATTERN of EDMG BRP-TX PPDUs used in the Responder BRP TXSS shall be set to QUASI_OMNI.

If the responder is DMG antenna reciprocal, then

— The TXSS-PPDUs field in the EDMG BRP Request element or EDMG BRP field within the BRP frame sent by the responder to acknowledge the BRP TXSS request shall be set to 0.
— The TRN field of the EDMG BRP-TX PPDUs used in the Responder BRP TXSS shall be transmitted using the DMG antenna corresponding to the best AWV configuration identified in the Initiator BRP TXSS.

If the responder is not antenna pattern reciprocal and is not DMG antenna reciprocal, the TXSS-PPDUs field in the EDMG BRP Request element or EDMG BRP field within the BRP frame sent by the responder to acknowledge the BRP TXSS request may be set to a value greater than 0.

If the initiator is not antenna pattern reciprocal and is not DMG antenna reciprocal, and the responder is antenna pattern reciprocal, the receive training of the initiator consist of the transmission of $R_{init} + 1$ EDMG BRP-RX PPDUs. For all other cases, the receive training of the initiator consists of the transmission of one EDMG BRP-RX PPDU.

If the initiator is DMG antenna reciprocal, the EDMG BRP-RX PPDU sent in the receive training of the initiator is received using the DMG antenna corresponding to the best AWV configuration identified in the Initiator BRP TXSS.

If the initiator is antenna pattern reciprocal and the responder is not antenna pattern reciprocal and is not DMG antenna reciprocal, the EDMG BRP-RX PPDU sent in the receive training of the initiator is received using the DMG antenna corresponding to the best AWV configuration identified in the Initiator BRP TXSS.

If the initiator is not antenna pattern reciprocal and is not DMG antenna reciprocal, and the responder is not antenna pattern reciprocal, the EDMG BRP-RX PPDU sent in the receive training of the initiator is received by the initiator with the DMG antenna corresponding to the best transmit AWV of the responder as identified in the Responder BRP TXSS.

The AWV configuration used in the transmission of the TRN field of the one or more EDMG BRP-RX PPDUs by the responder corresponds to the best AWV configuration identified in the receive training for the responder for the following cases:

— If the initiator is DMG antenna reciprocal and the responder is antenna pattern reciprocal.
— If the initiator is not antenna pattern reciprocal and is not DMG antenna reciprocal, and the responder is antenna pattern reciprocal.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The AWV configuration used in the transmission of the TRN field of the one or more EDMG BRP-RX PPDUs by the responder corresponds to the best AWV configuration identified in the Responder BRP TXSS for the following cases:

— If the initiator is antenna pattern reciprocal, and the responder is not antenna pattern reciprocal and is not DMG antenna reciprocal.

— If both the initiator and responder are DMG antenna reciprocal.

— If the initiator is DMG antenna reciprocal, and the responder is not antenna pattern reciprocal and is not DMG antenna reciprocal.

— If the initiator is not antenna pattern reciprocal and is not DMG antenna reciprocal, and the responder is DMG antenna reciprocal.

— If both the initiator and the responder are not antenna pattern reciprocal and are not DMG antenna reciprocal.

The examples given in Figure 10-122 (Example of BRP TXSS: responder performs measurements using one DMG antenna) and Figure 10-123 (Example of BRP TXSS: responder performs measurements using multiple DMG antennas simultaneously) correspond to a scenario in which the initiator and responder are not antenna pattern reciprocal and are not DMG antenna reciprocal.

An example BRP TXSS for the case when the initiator is antenna pattern reciprocal, and the responder is not antenna pattern reciprocal and is not DMG antenna reciprocal is shown in Figure 10-124 (Example of BRP TXSS: initiator is antenna pattern reciprocal, and responder is not antenna pattern reciprocal and is not DMG antenna reciprocal).

An example BRP TXSS for the case when the initiator is DMG antenna reciprocal, and the responder is antenna pattern reciprocal is shown in Figure 10-125 (Example of BRP TXSS: initiator is DMG antenna reciprocal, and responder is antenna pattern reciprocal).

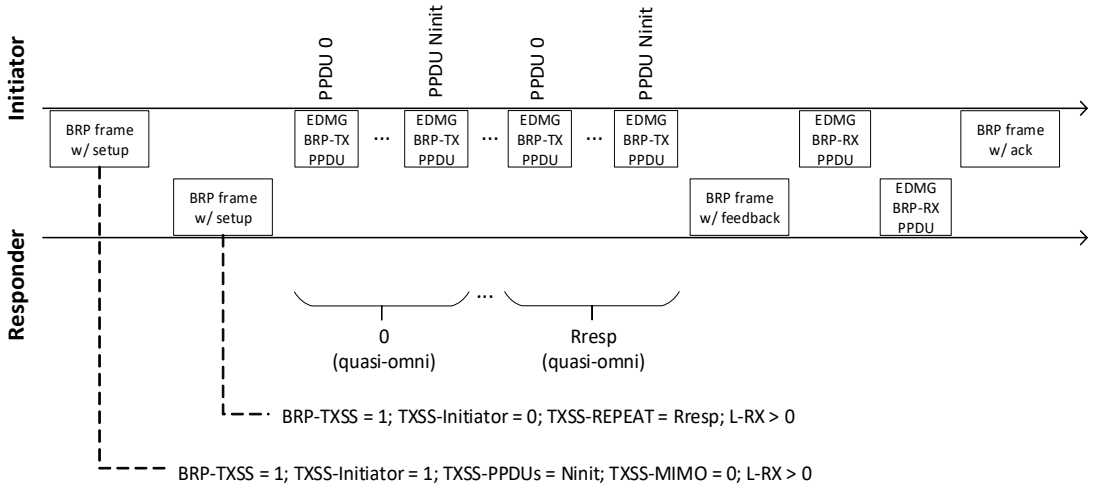

Figure 10-125—Example of BRP TXSS: initiator is DMG antenna reciprocal, and responder is antenna pattern reciprocal

10.41.10.5.2.4 MIMO BRP TXSS configuration

Receive training of the responder and receive training of the initiator shall not be performed in a MIMO BRP TXSS procedure. The L-RX field within the EDMG BRP Request element or EDMG BRP field in the BRP frames transmitted during the setup phase of a MIMO BRP TXSS shall be set to 0.

Responder BRP TXSS is mandatory in MIMO BRP TXSS.

Copyright © 2025 IEEE. All rights reserved.

An example of a MIMO BRP TXSS is shown in Figure 10-126 (Example of MIMO BRP TXSS).

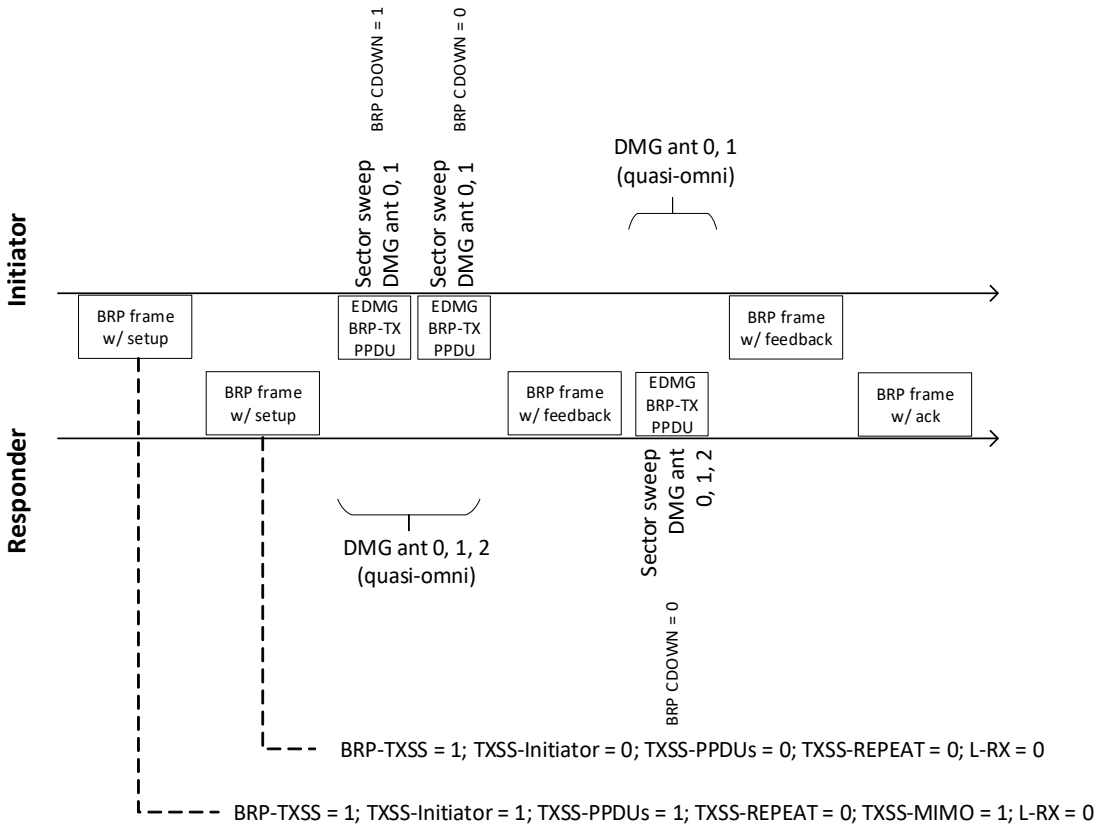

Figure 10-126—Example of MIMO BRP TXSS

BRP frames sent in a MIMO BRP TXSS shall be transmitted by applying spatial expansion and mapping a single space-time stream to all *N* transmit chains to be trained in the procedure. The TRN field of EDMG BRP-TX PPDUs sent in a MIMO BRP TXSS shall consist of *N* orthogonal waveforms, as defined in 28.9.2 (Beam refinement).

BRP frames transmitted in a MIMO BRP TXSS during the setup phase, with feedback within an Initiator BRP TXSS, with feedback within a Responder BRP TXSS, and with acknowledgment at the end of the procedure shall not include a TRN field.

In the setup phase of a MIMO BRP TXSS, if an implementation has not yet determined AWVs to use in some of its transmit chains (for example, if a station has been using a single transmit chain before the setup phase), the AWVs used by such chains should be selected in an implementation dependent manner.

The DMG antennas and AWVs used in the transmission of all fields, except for the TRN field of EDMG BRP-TX PPDUs sent in the Initiator BRP TXSS, the Responder BRP TXSS, and with acknowledgment, shall be the same ones used in the setup phase. The TRN field of EDMG BRP-TX PPDUs sent in a MIMO BRP TXSS may be transmitted with a different set of DMG antennas than the one used in the transmission of the remaining fields of the same PPDU.

Similarly, the DMG antennas and AWVs used in the reception of all fields, except for the TRN field of BRP frames sent in the Initiator BRP TXSS, the Responder BRP TXSS, and with acknowledgment, shall be the same ones used in the setup phase. The TRN field of EDMG BRP-TX PPDUs sent in a MIMO BRP TXSS

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

may be received with a set of DMG antennas that is not the same one used in the reception of the remaining fields of the same PPDU.

The Initiator BRP TXSS shall consist of the transmission of N_{init} + 1 EDMG BRP-TX PPDUs consecutively repeated R_{resp} + 1 times by the initiator followed by the transmission of a BRP frame with feedback by the responder. The EDMG BRP-TX PPDUs transmitted in an Initiator BRP TXSS shall be configured as follows:

— The TXVECTOR parameter TRN_RX_PATTERN of the PPDU shall be set to QUASI_OMNI.
— The TXVECTOR of the i^{th} EDMG BRP-TX PPDU within each of the R_{resp} + 1 repetitions, where $1 \le i \le N_{init}$ + 1, shall have the same value for the parameters EDMG_TRN_LEN, EDMG_TRN_P, EDMG_TRN_M, and EDMG_TRN_N.
— The TRN subfields of the i^{th} EDMG BRP-TX PPDU within each of the R_{resp} + 1 repetitions, where $1 \le i \le N_{init}$+1, shall be transmitted using the same set of DMG antennas and the same AWVs.
— The set of DMG antennas used when transmitting the TRN field of the N_{init} + 1 EDMG BRP-TX PPDUs within one of the R_{resp} + 1 repetitions in an Initiator BRP TXSS should be different.

Similarly, the Responder BRP TXSS shall consist of the transmission of N_{resp} + 1 EDMG BRP-TX PPDUs consecutively repeated R_{init} + 1 times by the responder followed by the transmission of a BRP frame with feedback by the initiator. The EDMG BRP-TX PPDUs transmitted in a Responder BRP TXSS shall be configured as follows:

— The TXVECTOR parameter TRN_RX_PATTERN of the PPDU shall be set to QUASI_OMNI.
— The TXVECTOR of the i^{th} EDMG BRP-TX PPDU within each of the R_{init} + 1 repetitions, where $1 \le i \le N_{resp}$ + 1, shall have the same value for the parameters EDMG_TRN_LEN, EDMG_TRN_P, EDMG_TRN_M, and EDMG_TRN_N.
— The TRN subfields of the i^{th} EDMG BRP-TX PPDU within each of the R_{init} + 1 repetitions, where $1 \le i \le N_{resp}$ + 1, shall be transmitted using the same set of DMG antennas and the same AWVs.
— The set of DMG antennas used when transmitting the TRN field of the N_{resp} + 1 EDMG BRP-TX PPDUs within one of the R_{init} + 1 repetitions in a Responder BRP TXSS should be different.

In both Initiator BRP TXSS and Responder BRP TXSS of a MIMO BRP TXSS, the set of DMG antennas used when receiving the TRN subfields of EDMG BRP-TX PPDUs of different repetitions should be different.

A STA that is part of a MIMO BRP TXSS shall provide feedback for each of the DMG antennas trained in the procedure, as defined in 10.41.10.5.3 (BRP TXSS execution).

The first TRN-Unit in an EDMG BRP PPDU used in a MIMO BRP TXSS may be used for the initiator and responder to switch one or more DMG antennas used and shall not be processed by the receiver. Therefore, for EDMG BRP-TX PPDUs transmitted in a MIMO BRP TXSS, the value of the TXVECTOR parameter EDMG_TRN_LEN shall be set to k + 1, where k is the number of TRN-Units used for transmit training. The TRN subfields that comprise the first TRN-Unit in EDMG BRP-TX PPDUs used as part of a MIMO BRP TXSS shall not be included in the TRN subfield and AWV feedback ID indexing procedures described in 28.9.2.2.5 (TRN field definition).

When transmitting an EDMG BRP-TX PPDU as part of a MIMO BRP TXSS, an EDMG STA may change the set of DMG antennas used in the transmission of its TRN field during the first TRN-Unit and shall not change DMG antennas during the remaining TRN-Units.

When receiving an EDMG BRP-TX PPDU as part of MIMO BRP TXSS, an EDMG STA may change the set of DMG antennas used in the reception of the TRN field during the first TRN-Unit and shall not change DMG antennas during the remaining TRN-Units.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

For EDMG BRP-TX PPDUs used in a MIMO BRP TXSS, the AWVs used in the transmission of the first *P* TRN subfields of each TRN-Unit depends on whether the set of DMG antennas used in the transmission of the EDMG BRP-TX PPDU changes at the beginning of the TRN field. If the TRN field of an EDMG BRP-TX PPDU is transmitted with the same set of DMG antennas as the remaining fields of the PPDU, the first *P* TRN subfields of each TRN-Unit shall be transmitted using the same DMG Antennas and AWVs as the remaining fields of the PPDU. If the set of DMG antennas used in the transmission of an EDMG BRP-TX PPDU changes at the beginning of the TRN field, the AWVs used in the transmission of the first *P* TRN subfields of each TRN-Unit are selected in an implementation dependent manner and should be the same for all TRN-Units.

10.41.10.5.2.5 Configuration of BRP TXSS for 2.16+2.16 GHz and 4.32+4.32 GHz channels

The initiator of a BRP TXSS requests to perform BRP TXSS over a 2.16+2.16 GHz or a 4.32+4.32 GHz channel by sending a BRP frame with setup that has the Channel Aggregation Requested field in the DMG Beam Refinement element set to 1 and with TXVECTOR parameter CHANNEL_AGGREGATION set to AGGREGATED. If the responder accepts the request by sending a BRP frame with setup with the Channel Aggregation Requested field set to 1 and the value of the TXVECTOR parameters CH_BANDWIDTH and CHANNEL_AGGREGATION equal to the value of the RXVECTOR parameters CH_BANDWIDTH and CHANNEL_AGGREGATION of the BRP frame sent by the initiator, all BRP frames sent as part of the BRP TXSS shall have the same TXVECTOR parameters CH_BANDWIDTH and CHANNEL_AGGREGATION.

BRP frames sent in a BRP TXSS performed in a 2.16+2.16 GHz or a 4.32+4.32 GHz channel during the setup phase or with the TXVECTOR parameter EDMG_TRN_LEN greater than 0 shall be sent using the EDMG control mode. BRP frames sent in a BRP TXSS with feedback or with acknowledgment shall be transmitted using an EDMG PPDU or a non-EDMG duplicate PPDU. As defined in 28.3.3.3.2.2 (Definition for EDMG control mode PPDU), the total number of transmit chains, N_{TX}, is an even number, and the first $N_{TX}/2$ transmit chains are used for transmission on the primary channel and the second $N_{TX}/2$ transmit chains are used for transmission on the secondary channel. In the setup phase, if an implementation has not yet determined AWVs to use in the secondary channel, the AWVs used by the $N_{TX}/2$ transmit chains used for transmission on the secondary channel is selected in an implementation dependent manner. If a BRP frame sent in a BRP TXSS performed in a 2.16+2.16 GHz or a 4.32+4.32 GHz includes a TRN field, the TXVECTOR parameter TRN_AGGREGATION shall be set to AggregationTRN.

If the TXSS-MIMO field within the EDMG BRP Request element or EDMG BRP field in a BRP frame with setup sent by the initiator is equal to 0, the BRP TXSS shall be configured as described in 10.41.10.5.2 (BRP TXSS configuration). If the TXSS-MIMO field is equal to 1, the BRP TXSS shall be configured as described in 10.41.10.5.2 (BRP TXSS configuration). In both cases, the values of the TXSS-PPDUs and TXSS-REPEAT fields exchanged during the setup correspond to the number of PPDUs and of repetitions, respectively, in each of the two aggregated channels.

A STA that is part of a BRP TXSS that is performed over a 2.16+2.16 GHz or a 4.32+4.32 GHz channel shall provide feedback for each of the two aggregated channels. BRP frames with feedback in this case shall have the Channel Aggregation Present field within the DMG Beam Refinement element set to 1.

10.41.10.5.3 BRP TXSS execution

A BRP TXSS shall complete within the CBAP or SP in which it was initiated.

The FBCK-REQ subfield in the DMG Beam Refinement element carried within the BRP frame that initiates a BRP TXSS shall be set to 10001 (binary).

To request a BRP TXSS, the initiator sends a BRP frame with both the BRP-TXSS field and the TXSS-INITIATOR field within the EDMG BRP Request element or EDMG BRP field set to 1 and the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

TXSS-PPDUs field set to indicate the number of EDMG BRP-TX PPDUs necessary for the initiator to perform transmit training. To confirm the BRP TXSS execution, the responder shall respond with a BRP frame MBIFS after the reception of the BRP frame sent by the initiator with the BRP-TXSS field within the EDMG BRP Request element or EDMG BRP field set to 1, the TXSS-INITIATOR field set to 0, and the TXSS-REPEAT field set to indicate the number of requested repetitions of the EDMG BRP-TX PPDUs sent by the initiator.

If the procedure includes a Responder BRP TXSS, the TXSS-REPEAT field in the BRP frame sent by the initiator shall be set to indicate the number of requested repetitions of the EDMG BRP-TX PPDUs sent by the responder, and the TXSS-PPDUs field in the BRP frame sent by the responder shall be set to indicate the number of EDMG BRP-TX PPDUs necessary for the responder to perform transmit training. If the procedure does not include a Responder BRP TXSS, the TXSS-REPEAT field in the BRP frame sent by the initiator shall be set to 0 and the TXSS-PPDUs field in the BRP frame sent by the responder shall be set to 0.

The TXSS-MIMO subfield in the EDMG BRP Request element or EDMG BRP field of the BRP frame that initiates the BRP TXSS shall be set to 1 when the procedure is a MIMO BRP TXSS. If the procedure is a SISO BRP TXSS, the TXSS-MIMO subfield shall be set to 0. Both initiator and responder of a BRP TXSS shall be SU-MIMO capable (as defined in 10.41.10.2.2 (SU-MIMO beamforming)) for the TXSS-MIMO subfield to be set to 1.

The initiator shall transmit the first EDMG BRP-TX PPDU MBIFS after the reception of the BRP frame sent by the responder confirming the BRP TXSS execution.

The EDMG BRP-TX PPDUs sent by the initiator in a BRP TXSS procedure shall be separated by SIFS. The responder shall then send a BRP frame to the initiator containing feedback based on measurements it performed during the Initiator BRP TXSS. The BRP frame with feedback transmitted by the responder is separated from the last EDMG BRP-TX PPDU transmitted by the initiator by an MBIFS.

A BRP frame with feedback transmitted in a BRP TXSS may have the EDMG-SHORT-FBCK field set to 0 or 1. If the EDMG-SHORT-FBCK field is 0, the BRP frame shall have the SNR Present subfield within the FBCK-TYPE field set to 1, the Sector ID Order subfield set to 1, the EDMG Extension Flag set to 1 and the EDMG Channel Measurement Present set to 1. The EDMG Sector ID Order field indicates the AWV IDs, TX antennas and RX antennas of sectors that were received in the procedure. If the EDMG-SHORT-FBCK field is 1, the Sector ID/CDOWN/AWV ID subfield indicates the Sector ID of a PPDU received in the sector sweep. For both cases, when the EDMG-SHORT-FBCK field is 0 or 1, the SNR subfields indicate the SNRs with which the BRP PPDUs received through the corresponding sectors were received and the BRP-CDOWN subfields associated with each SISO ID indicate the BRP-CDOWN values within the BRP PPDUs received from the corresponding sector.

In an Initiator BRP TXSS, the BRP CDOWN field within the EDMG BRP Request element or EDMG BRP field in each transmitted EDMG BRP-TX PPDU shall contain the total number of transmissions remaining until the end of the Initiator BRP TXSS, such that the first EDMG BRP-TX PPDU transmitted in the Initiator BRP TXSS has the BRP CDOWN field set to $(N_{init} + 1) \times (R_{resp} + 1) - 1$ and the last PPDU has the BRP CDOWN field set to 0. The use of BRP CDOWN is illustrated in Figure 10-122 (Example of BRP TXSS: responder performs measurements using one DMG antenna) and Figure 10-123 (Example of BRP TXSS: responder performs measurements using multiple DMG antennas simultaneously).

If the BRP TXSS includes receive training of the responder, the initiator shall transmit one EDMG BRP-RX PPDU MBIFS after the reception of the BRP frame sent by the responder with feedback of the Initiator BRP TXSS.

If the procedure includes a Responder BRP TXSS, the responder shall send the first EDMG BRP-TX PPDU MBIFS after the EDMG BRP-RX PPDU sent by the initiator or, if receive training of the responder is not

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

performed, the BRP frame with feedback transmitted by the responder within the Initiator BRP TXSS. The EDMG BRP-TX PPDUs sent by the responder in a BRP TXSS procedure shall be separated by SIFS.

The BRP CDOWN field within the EDMG BRP Request element or EDMG BRP field in each transmitted EDMG BRP-TX PPDU shall contain the total number of transmissions remaining until the end of the Responder BRP TXSS, such that the first EDMG BRP-TX PPDU transmitted in the Responder BRP TXSS has the BRP CDOWN field set to $(N_{resp} + 1) \times (R_{init} + 1) - 1$, and the last PPDU has the BRP CDOWN field set to 0.

If the BRP TXSS includes a Responder BRP TXSS, the initiator shall send a BRP frame to the responder containing feedback based on measurements it performed. The BRP frame with feedback transmitted by the initiator is separated from the last EDMG BRP-TX PPDU transmitted by the responder by an MBIFS.

If the BRP TXSS includes receive training of the initiator, the responder shall transmit the first EDMG BRP-RX PPDU MBIFS after the reception of the BRP frame sent by the initiator with feedback of the Responder BRP TXSS or, if Responder BRP TXSS is not performed, of the EDMG BRP-RX PPDU transmitted by the initiator. The EDMG BRP-RX PPDUs sent by the responder shall be separated by SIFS.

If the BRP TXSS includes receive training of the initiator, the initiator shall transmit a BRP frame with acknowledgment MBIFS after the reception of the last EDMG BRP-RX PPDU transmitted by the responder if it was successfully received. If the BRP TXSS does not include receive training of the initiator, the responder shall transmit a BRP frame with acknowledgment if the last BRP frame sent by the initiator was successfully received.

The responder and initiator of a SISO BRP TXSS shall start using the AWV configurations identified in the procedure immediately after the transmission of the BRP frame with acknowledgment.

If the TXSS-MIMO subfield in the EDMG BRP Request element or EDMG BRP field of the BRP frame that initiated the BRP TXSS was set to 1, the initiator shall start the MIMO phase of SU-MIMO beamforming training an MBIFS following the completion of the BRP TXSS.

10.41.10.6 First path beamforming training

First path beamforming training (FPBT) is a procedure used to determine the best AWV corresponding to the first path. The first path is defined to be the propagation path between TX and RX that is estimated to have the shortest time of flight. In line of sight (LOS) conditions, the first path corresponds to the LOS path. If several AWVs have the same estimated shortest time of flight, the beamforming training shall select among them the first path as the one with best quality. The method a STA uses to determine the first path and the first path with best quality is implementation dependent and beyond the scope of this standard.

Prior to performing the FPBT, the two EDMG STAs are assumed to know their best transmit AWV and receive AWV for data communication. A FPBT shall be completed within the CBAP or SP in which it was initiated. An EDMG STA that has the First Path Beamforming Training Supported subfield in the STA's RSNXE set to 1 is FPBT capable.

An EDMG STA shall not initiate FPBT with a peer EDMG STA that is not FPBT capable.

The FPBT procedure is the same as BRPTXSS procedure (see 10.41.10.5) except for the following differences:

— FPBT shall be performed in SISO configuration defined in 10.41.10.5.2 with any valid combination of TXVECTOR parameter, CH_BANDWIDTH, and CH_AGGREGATION. FPBT shall not be performed in MIMO configuration. All the phases of the BRP-TXSS procedure shall be supported in FPBT. Selection of which phases are used is dependent on the DMG antenna reciprocity and

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

antenna pattern reciprocity properties of the involved EDMG STAs as defined in their DMG STA Capability Information field.

— In the setup phase, the EDMG STA shall transmit a BRP frame with the First Path Beamforming Training subfield set to 1 to request FPBT. An EDMG STA that is FPBT capable, and receives a BRP frame with the First Path Beamforming Training subfield equal to 1, shall set the First Path Beamforming Training subfield to 1 in the BRP frame that it sends in response to the reception of the BRP frame.

— In a BRP transaction (Initiator BRP TXSS, receive training phase of the responder, Responder BRP TXSS, and receive training phase of the initiator) that is part of a first path beamforming training, all transmitted BRP frames shall have the First Path Beamforming Training subfield set to 1 and shall have the FIRST_PATH_TRAINING parameter in the TXVECTOR set to 1. In such a transaction, all TX and RX beamforming training using the TRN field is used to find the AWV of the first path and not the best path. The AWV selected by the FPBT shall not be used for data transmission. It shall be used only in the FTM procedure defined in 11.21.6.4.2.6.

The TRN field of the EDMG BRP-RX PPDU used for the receive training phase of the responder:

— Shall be transmitted with the best first path AWV identified in the preceding Initiator BRP TXSS phase.

— Shall be received with the DMG antenna corresponding to the best first path AWV configuration identified in the preceding Initiator BRP TXSS phase.

— When the receive training phase of the initiator is performed, the TRN field of the EDMG BRP-RX PPDUs used in this phase shall be transmitted with the best first path AWV identified in the preceding Responder BRP TXSS phase or in the receive training of the responder, as defined in 10.41.10.5.2.

10.41.10.7 Dual polarization TRN beamforming training

Dual polarization TRN beamforming training may be used to assist a pair of EDMG STAs to determine if a beamformed link between them uses line-of-sight or non-line-of-sight propagation.

An EDMG STA supports dual polarization TRN beamforming training if the Dual Polarization TRN Supported subfield in the STA’s EDMG Capabilities element is 1.

An EDMG STA may initiate dual polarization TRN beamforming training with a peer EDMG STA if the peer STA

— Supports dual polarization TRN beamforming training and

— Indicates that it is capable of sending channel measurement feedback by setting the Chan-FBCK-CAP subfield to 1 in the last BRP Request field transmitted by the peer STA to the initiating STA.

Dual polarization TRN beamforming shall include at least a setup phase that consists of BRP frame from the initiator followed by a BRP frame from the responder, which is followed by a TRN training phase and the

Copyright © 2025 IEEE. All rights reserved.

responder's channel measurement feedback as shown in Figure 10-127 (Dual polarization TRN beamforming training procedure).

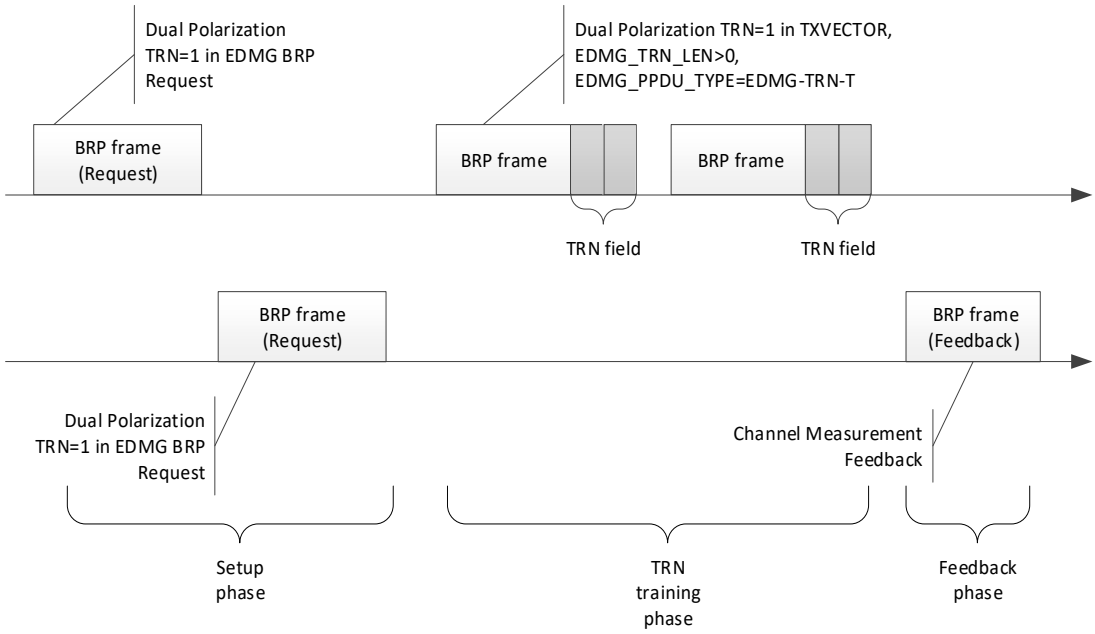

Figure 10-127—Dual polarization TRN beamforming training procedure

In the setup phase, to request dual polarization TRN beamforming training, an initiating STA shall transmit a BRP frame to a responding STA that includes an EDMG BRP Request element with the following field setting:

— Dual PolarizationTraining set to 1
— TXSS-initiator set to 1
— TXSS-Repeat > 0

To conclude the setup phase, the responder shall respond, in a SIFS following the reception of the BRP frame from the initiator, with a BRP frame that contains an EDMG BRP Request element with the following field setting:

— Dual PolarizationTraining set to 1
— TXSS-initiator set to 0

During the dual polarization transmit training phase, the initiator sends PPDUs with TRN subfields within the TRN field switching polarization as described in 28.9.2.2.5 (TRN field definition), with the following TXVECTOR parameter setting:

— DUAL_POL_TRAINING set to 1.
— EDMG_PPDU_TYPE set to either EDMG-TRN-T or EDMG-TRN-R/T.
— EDMG_TRN_LEN set to a value greater than 0.
— EDMG_TRN_N set to either 1 or 3 (for EDMG_TRN_N=1, two consecutive TRN subfields have alternate polarization, e.g., horizontal vertical (HV) or vertical horizontal (VH); for EDMG_TRN_N=3, the polarization changes after two consecutive TRN subfields, e.g., HHVV or VVHH).

In the TRN training phase, when changing polarizations, the initiator shall change the TRN subfields polarizations with a 90 degrees rotation in a clockwise direction. For example for HV, the polarization

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

changes from TRN horizontal polarization direction to vertical polarization direction via a 90 degrees clockwise rotation. As the responder receives the PPDUs in the dual polarization transmit training phase, it measures the signal strength of the dual polarized received TRN subfield as described in 28.9.2.2.5 (TRN field definition). This might require the responder to switch the receive polarization.

In the feedback phase, the responder responds with a BRP frame with the Channel Measurement Feedback element and EDMG Channel Measurement Feedback element that includes the Dual Polarization TRN Measurement field.

The initiator may use the received feedback to estimate if the communication link with the responder is NLOS or LOS.

If, in addition to the TXVECTOR parameters specified above in this subclause, the initiator sets the FIRST_PATH_TRAINING parameter to 1 and the First Path Training field of the EDMG BRP Request element to 1, the responder shall perform the measurement on the first arrival path and respond with a BRP frame with Channel Measurement Feedback element and EDMG Channel Measurement Feedback element with the Dual Polarization TRN field and First Path Training fields in the EDMG BRP Request element set to 1.

10.41.11 TDD beamforming

10.41.11.1 General

The following TDD beamforming procedures are defined in this subclause:

— TDD individual beamforming: a single STA (initiator) transmits a series of TDD SSW frames through its sectors while a target STA (responder) sweeps the receive sectors specified by MLME-SCAN.request or MLME-TDD-BEAM-MEASUREMENT.request primitives. If the responder receives at least one TDD SSW frame, by exchanging additional frames both initiator and responder are made aware of one or more combinations of transmit beam on the initiator side and receive beam on the responder side that enable communication between the two STAs.

— TDD group beamforming: a single STA (initiator) transmits a series of TDD SSW frames through its sectors while two or more target STAs (responders) sweep the receive sectors specified by MLME-SCAN.request or MLME-TDD-BEAM-MEASUREMENT.request primitives at each target STA. For each responder that receives at least one TDD SSW frame, by exchanging additional frames both initiator and responder are made aware of one or more combinations of transmit beam on the initiator side and receive beam on the responder side.

— TDD beam measurement: a single STA (initiator) transmits a series of TDD SSW frames while a single target STA (responder), or alternatively a group of target STAs (responders), sweep their respective receive sectors. The primary difference between TDD beam measurement and other TDD beamforming procedures is that in TDD beam measurement responders transmit an Announce frame with a TDD Route element to the initiator during the procedure only upon request, and additionally, report the measurement results to the SME.

As specified in 11.54.2, unscheduled TDD beamforming is referred to as the TDD beamforming scheduled via the Transmit Period field within a TDD SSW frames. If TDD beamforming is scheduled via the TDD Slot Schedule element, it is referred to as scheduled TDD beamforming.

After the completion of the TDD beamforming procedure, the responder shall send to the initiator Announce frames containing TDD Route element with the results of the TDD beamforming. For unscheduled TDD beamforming, the initiator and responder may perform the authentication and association procedure described in 11.54.3 (Scheduling for association and secure authentication).

All TDD beamforming procedures shall be performed during a TDD SP.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The TDD individual and group beamforming procedures assume antenna reciprocity for both the initiator and responder STAs. A TDD Beamforming frame is a TDD SSW frame, a TDD SSW Feedback frame or a TDD SSW Ack frame.

Figure 10-128 (Example of TDD individual beamforming training) gives an example of the TDD individual beamforming training procedure.

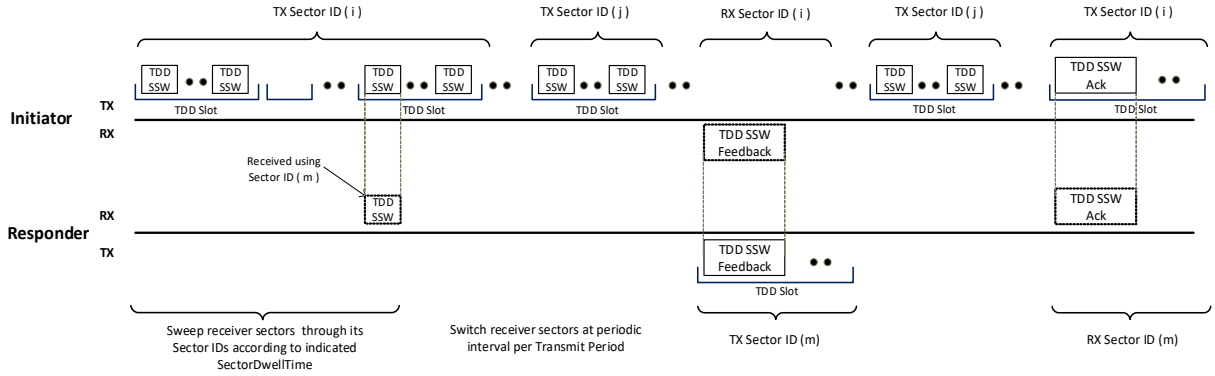

Figure 10-128—Example of TDD individual beamforming training

During TDD individual beamforming training, a STA that has not established a DMG control mode connection with an intended peer switches its antenna configuration through all its receive sectors. In order to establish a DMG control mode connection, an initiator sends multiple TDD SSW frames during its assigned TDD slots. A TDD SSW frame indicates to the responder the TX Sector ID used by the initiator for the transmission of the TDD SSW frame and, in case of unscheduled TDD beamforming, the frame also includes the time offset for which the responder should send its TDD SSW Feedback frame as response and the time offset the responder shall be ready to receive one or more TDD SSW Ack frames sent to increase robustness. The responder sends its TDD SSW Feedback frame with the same sector it received the TDD SSW frame with the best quality. Following the reception of a TDD SSW Feedback frame, the initiator sends a TDD SSW Ack frame that acknowledges the received configuration.

During TDD individual BF training, the TDD SSW frame is sent periodically and is repeated multiple times for each TX Sector ID. The TDD individual BF training sequence continues until the initiator sets the End of Training subfield in the TDD SSW Ack frame to 1. In unscheduled TDD beamforming, the TDD SSW Ack frame includes also a time offset indication in the Initiator Transmit Offset subfield on when the responder obtains the network configuration parameters and time offset indication in the Responder Transmit Offset subfield on when the responder reports the results of the TDD individual BF procedure.

Figure 10-129 (Example of TDD group beamforming training) gives an example of the TDD group beamforming training procedure.

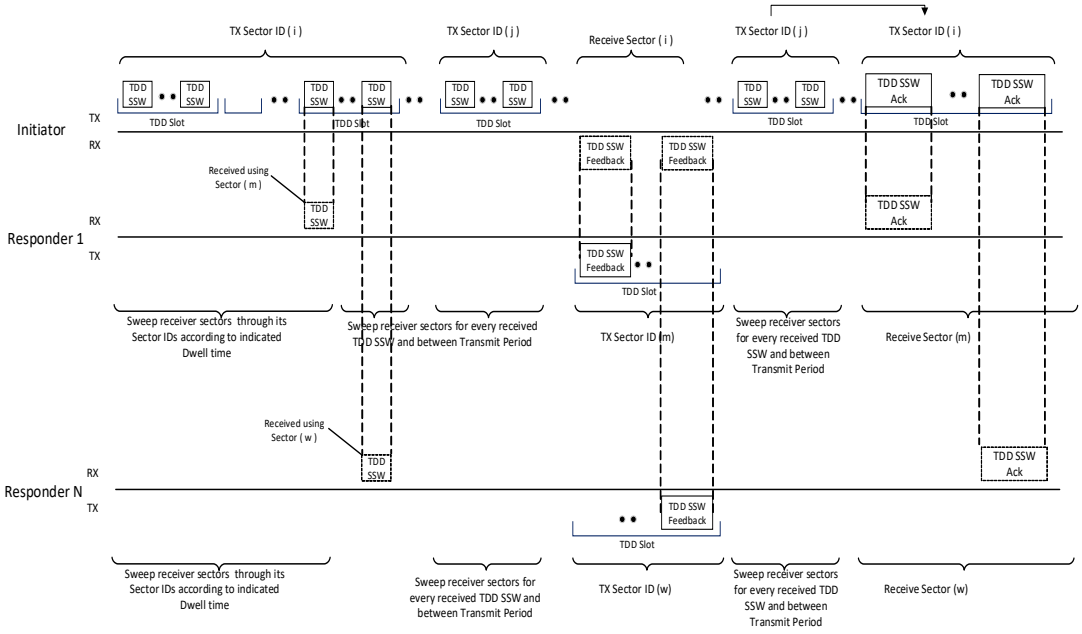

Figure 10-129—Example of TDD group beamforming training

A STA participating in TDD group beamforming training and that has not established a DMG control mode connection with an intended peer switches its antenna configuration through all its receive sectors. In order to establish a DMG control mode connection, an initiator sends multiple TDD SSW frames during its assigned TDD slots. A TDD SSW frame indicates to the responders the TX Sector ID used by the initiator for the transmission of the TDD SSW frames and, in case of unscheduled TDD beamforming, the frame also includes the time offset for which each responder should send its TDD SSW Feedback frame as response and the time offset each responder shall be ready to receive a TDD SSW Ack frame. Each responder sends its TDD SSW Feedback frame with the same sector it received the TDD SSW frame with the best quality. Following the reception of a TDD SSW Feedback frame, the initiator sends a TDD SSW Ack frame to each responder that acknowledges the received configuration.

During the TDD group BF training, the TDD SSW frame is sent periodically and is repeated multiple times for each TX Sector ID. The TDD group BF training sequence for each responder continues until the initiator sets the End of Training subfield in the TDD SSW Ack frame to 1 for the corresponding responder. For unscheduled TDD beamforming, the initiator also indicates in the Initiator Transmit Offset subfield the time offsets on when the corresponding responder obtains the TDD Slot Schedule element for allocated TDD slots for further TDD link access operation and in the Responder Transmit Offset subfield the time offset on when the corresponding responder reports the results of the TDD group BF procedure. The initiator can end a TDD group BF training with the responders simultaneously or individually. This is implementation dependent and beyond the scope of this standard.

10.41.11.2 Initiator operation for TDD individual beamforming

For TDD individual beamforming, the BFType parameter is set to TDD Individual BF in the MLME-TDD-BF-TRAINING.request primitive.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

To initiate TDD individual beamforming with a known responder, the initiator shall send multiple TDD SSW frames with the RA field set to the Responder STA's MAC address as indicated by the PeerSTAAddress parameter of the MLME-TDD-BF-TRAINING.request primitive.

To initiate TDD individual beamforming with an unknown responder, the initiator shall send TDD SSW frames with the RA field set to the broadcast address. The initiator should switch the RA field in a transmitted TDD SSW frame to responder's MAC address after receiving a TDD SSW Feedback frame from the intended responder.

TDD SSW frames that are sent from the same transmit DMG antenna shall have the same TX Antenna ID subfield value. TDD SSW frames that are sent from the same transmit antenna sector shall have the same TX Sector ID, Beamforming Time Unit, Transmit Period, Responder Feedback Offset, Initiator Ack Offset and Number of Requested Feedback subfield values. These frames shall be transmitted with the same transmit power and the PPDUs carrying these frames shall not include TRN fields.

The initiator shall send TDD SSW frames through all the DMG antennas and all the sectors indicated by the TX antenna index and TX sector index values as indicated in the TXAntennaSectorIDList parameter of the MLME-TDD-BF-TRAINING.request primitive. Moreover, for each DMG antenna and for each sector, the initiator shall send TDD SSW frames with the same TX Antenna ID and TX Sector ID subfields values for the number of times indicated in the NumOfTDDSlotPerTXSector parameter multiplied by NumOfSSWPerTDDSlot parameter of the MLME-TDD-BF-TRAINING.request primitive. If the initiator transmits a TDD SSW Ack frame, the initiator shall send as many TDD SSW Ack frames as the number indicated in the NumOfAckPerTDDSlot parameter of the MLME-TDD-BF-TRAINING.request primitive.

The Transmit Period subfield value within TDD SSW frames shall remain the same throughout a TDD beamforming training. If the value of the Transmit Period subfield is nonzero, at the time offset equal to the Transmit Period subfield value the initiator shall transmit a TDD SSW frame of the TDD beamforming training with the same Count Index value.

If the link between the initiator and responder is in the active state (see 11.54 (TDD channel access operation)), and the initiator has sent the responder at least one frame with a TDD Slot Structure element and a TDD Slot Schedule element, then the initiator should use BF TDD slots to send TDD SSW and TDD SSW Ack frames to the responder. In this case, the Transmit Period, Responder Feedback Offset, Initiator Ack Offset, Initiator Transmit Offset and Responder Transmit Offset subfields shall be set to 0.

TDD SSW and TDD SSW Ack frames transmitted in the same TDD slot shall be separated with SBIFS and shall have a strictly increasing Count Index subfield value. The first TDD SSW frame or TDD SSW Ack frame transmitted in a TDD slot shall have the Count Index subfield set to 0. The Responder Feedback Offset subfield shall be equal in all TDD SSW frames transmitted in the same TDD slot. The Initiator Ack Offset subfield shall be equal in all TDD SSW frames transmitted in the same TDD slot. The Initiator Transmit Offset subfield shall be equal in all TDD SSW Ack frames transmitted in the same TDD slot. The Responder Transmit Offset subfield shall be equal in all TDD SSW Ack frames transmitted in the same TDD slot.

To receive a TDD SSW Feedback frame from the responder, the initiator shall set its receive antenna to the same DMG antenna and sector that were indicated, respectively, in the TX Antenna ID and TX Sector ID subfield of the corresponding TDD SSW frame, at the following offset calculated as a spacing from the end of the transmitted TDD SSW frame to the start of the expected transmission of the TDD SSW Feedback frame by the responder:

$$ResponderFeedbackOffset - [(CountIndex + 1) \times \text{TXTIME(TDD SSW)} + (CountIndex \times \text{SBIFS})] \quad (10\text{-}20)$$

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

where

ResponderFeedbackOffset is the value of the Responder Feedback Offset subfield in the TDD SSW frame with the same TX Sector ID within the same TDD slot

CountIndex is the value of the Count Index subfield in the transmitted TDD SSW frame

Figure 10-130 (TDD SSW Feedback frame transmit time for unscheduled TDD individual BF) depicts the timing to transmit the TDD SSW Feedback frame for unscheduled TDD individual BF.

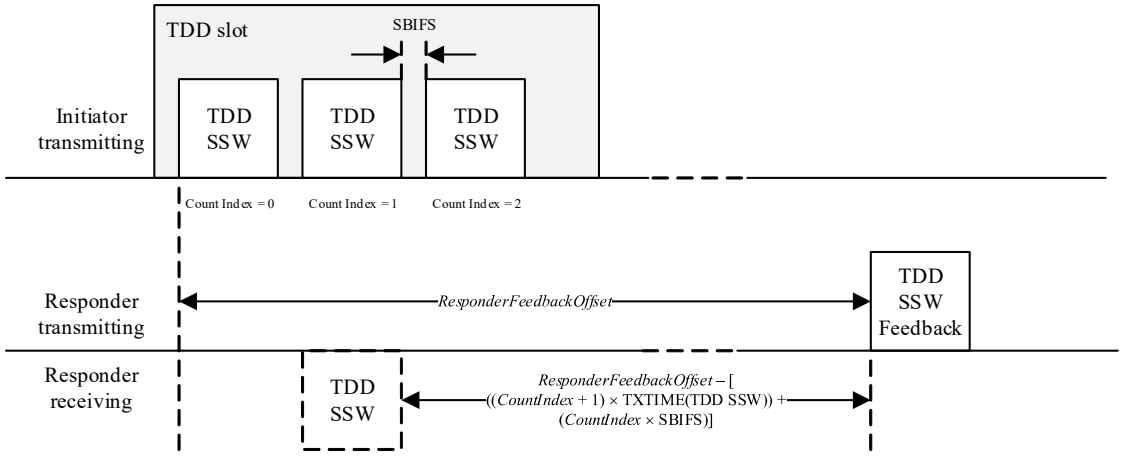

Figure 10-130—TDD SSW Feedback frame transmit time for unscheduled TDD individual BF

If the initiator received a TDD SSW Feedback frame, it shall transmit one or more TDD SSW Ack frames to the responder. To transmit these frames, the initiator shall set its DMG antenna and sector to the Decoded TX Antenna ID and the Decoded TX Sector ID from the last received TDD SSW Feedback frame. The transmission of the first TDD SSW Ack frame shall start at the following offset calculated as a spacing from the end of the transmitted TDD SSW frame to the start of the transmission of the first TDD SSW Ack frame:

$$InitiatorAckOffset - [(CountIndex + 1) \times \text{TXTIME(TDD SSW)} + (CountIndex \times \text{SBIFS})] \quad (10\text{-}21)$$

where

InitiatorAckOffset is the value of the Initiator Ack Offset subfield in the TDD SSW frame with the same TX Sector ID within the same TDD slot

CountIndex is the value of the Count Index subfield in the transmitted TDD SSW frame

The TDD SSW Ack frame shall include in the Decoded TX Sector ID subfield the sector indicated by the responder in the TX Sector ID subfield, in the Decoded TX Antenna ID subfield the sector indicated by the responder in the TX Antenna ID subfield of the TDD SSW Feedback frame last received by the initiator, the measured SNR of the decoded TDD SSW Feedback frame in the SNR Report subfield and, when performing unscheduled TDD beamforming, the time offsets to exchange frames containing TDD Route, TDD Slot Structure and TDD Slot Schedule elements.

For TDD individual BF, an initiator may request the responder to stop its receive sector sweeping by setting the End of Training subfield to 1 in transmitted TDD SSW frames. Upon reception of a TDD SSW Feedback frame with the End of Training subfield equal to 1, the initiator shall send one or more TDD SSW Ack frames to the responder with End of Training subfield set to 1 at the time offset indicated by Equation (10-21) or, alternatively, during assigned BF TDD slots. After sending a TDD SSW Ack frame with End of Training subfield equal to 1, the initiator shall configure its receive and transmit DMG antenna and sector index as indicated, respectively, in the Decoded TX Antenna ID and Decoded TX Sector ID subfields of the TDD SSW Feedback frame received from the responder in which its End of Training

Copyright © 2025 IEEE. All rights reserved.

subfield was set to 1. The initiator shall use this DMG antenna and sector for its subsequent transmissions and receptions with the responder, until another sector is negotiated.

After the initiator has sent the TDD SSW Ack frame with the End of Training subfield set to 1 to the responder, it may transmit a single PPDU other than a TDD Beamforming frame to the responder. To transmit the frame, the initiator shall set its antennas to the Decoded TX Sector ID and the Decoded TX Antenna ID from the last received TDD SSW Feedback frame. The transmission of the frame shall start at the following offset calculated as a spacing from the end of the transmitted TDD SSW Ack frame with the End of Training subfield set to 1 to the start of the expected transmission:

$$InitiatorTransmitOffset - [(CountIndex + 1) \times \text{TXTIME(TDD SSW Ack)} + (CountIndex \times \text{SBIFS})] \quad (10\text{-}22)$$

where

InitiatorTransmitOffset is the value of the Initiator Transmit Offset subfield in the TDD SSW Ack frame with the End of Training subfield set to 1

CountIndex is the value of the Count Index subfield in the transmitted TDD SSW Ack frame with the End of Training subfield set to 1

Subsequent opportunities for the initiator to transmit to the responder are separated by the value of the Transmit Period subfield in the TDD SSW Ack frame with the End of Training subfield set to 1.

After the initiator has sent the last TDD SSW Ack frame with the End of Training subfield set to 1 to the responder, it shall be ready to receive a single PPDU other than a TDD Beamforming frame from the responder by setting its receive DMG antenna and sector to the Decoded TX Antenna ID and the Decoded TX Sector ID from the last received TDD SSW Feedback frame, at the following offset calculated as a spacing from the end of the transmitted TDD SSW Ack frame with the End of Training subfield set to 1 to the start of the expected reception of the frame:

$$ResponderTransmitOffset - [(CountIndex + 1) \times \text{TXTIME(TDD SSW Ack)} + (CountIndex \times \text{SBIFS})] \quad (10\text{-}23)$$

where

ResponderTransmitOffset is the value of the Responder Transmit Offset subfield in the TDD SSW Ack frame with the End of Training subfield equal to 1

CountIndex is the value of the Count Index subfield in the transmitted TDD SSW Ack frame with the End of Training subfield equal to 1

Subsequent opportunities for the responder to transmit to the initiator are separated by the value of the Transmit Period subfield in the TDD SSW Ack frame with the End of Training subfield set to 1.

For the unscheduled TDD beamforming procedure, Equation (10-20) and Equation (10-21) establish transmit opportunities to exchange TDD Beamforming frames, and Equation (10-22) and Equation (10-23) establish transmit opportunities to exchange frames other than TDD Beamforming frames after TDD beamforming training completion with the responder.

In the unscheduled TDD beamforming procedure, upon transmission of the last TDD SSW Ack frame with End of Training subfield equal to 1, the initiator shall transmit an Announce frame to the responder, at the time offset indicated by Equation (10-22). The Announce frame shall include a TDD Slot Structure element. The initiator shall then, at the time offset indicated by Equation (10-23), be ready to receive a frame from the responder. If necessary, the initiator shall transmit additional frames at the periodic transmit opportunities following the time offset indicated by Equation (10-22), and shall be ready to receive additional frames at the periodic opportunities following the offset indicated by Equation (10-23).

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In the scheduled TDD beamforming procedure, the initiator shall send TDD SSW and TDD SSW Ack frames during BF TDD slots assigned to transmit from the initiator to the responder. The exchange of TDD Route elements takes place during Basic or Data TDD slots available to the initiator and to the responder after completion of the TDD beamforming training with the responder.

10.41.11.3 Responder operation for TDD individual beamforming

A responder STA that has is in inactive state (see 11.54 (TDD channel access operation)), or has not yet received a TDD SSW frame, or has not yet acquired the TDD Slot Structure element used by the BSS shall sweep its receiver antenna through all its receive sectors while dwelling on each sector for a time equal to SectorDwellTime as indicated by the MLME-TDD-BF-SCAN.request primitive.

NOTE 1—To increase the likelihood of detecting the initiator's TDD SSW frame, the responder SME can set SectorDwellTime to at least [2 × TXTIME (TDD SSW) + SBIFS].

Figure 10-131 (Responder's receiver sweeping for unscheduled TDD individual BF) gives an example of the responder's receiver sweeping procedure for unscheduled TDD individual BF.

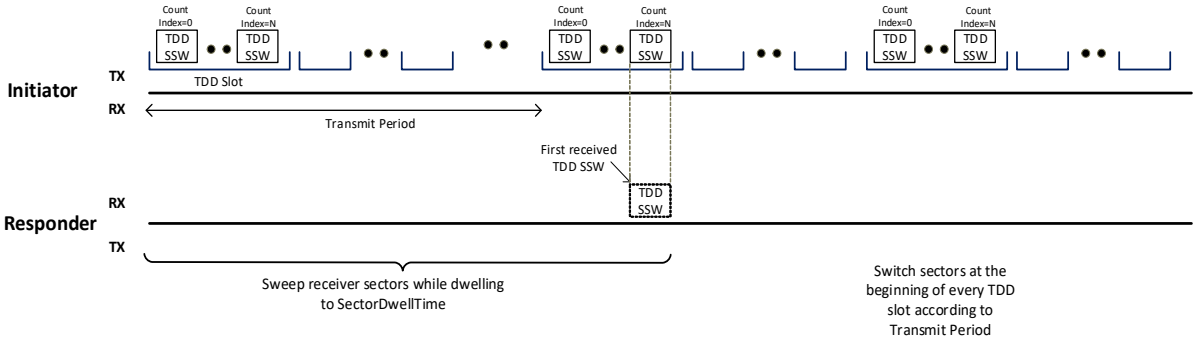

Figure 10-131—Responder's receiver sweeping for unscheduled TDD individual BF

Once the first TDD SSW frame is received, the responder proceeds with the following operation.

Upon reception on a receive sector of a TDD SSW frame with the RA field set to its MAC address or to the broadcast address, a responder shall switch within the TDD slot to its next receive sector to be ready to receive the next TDD SSW frame transmission within SBIFS. The responder shall switch its receive sector at the beginning of every TDD slot used for BF training at the time specified by a nonzero Transmit Period subfield in the received TDD SSW frame. While sweeping through its receive sectors, the responder shall continue decoding all the received TDD SSW frames.

NOTE 2—Switching the receive sectors after reception of each TDD SSW frame increases the number of trained receive sectors at the expense of receive sector measurement quality.

The responder shall transmit a TDD SSW Feedback frame using the DMG antenna and sector from which the responder received the TDD SSW with the best link quality at the time indicated by Equation (10-20) or, alternatively, during an assigned BF TDD slot. The TDD SSW Feedback frame shall include the DMG antenna index and sector index used by the initiator to transmit the TDD SSW frame in the, respectively, Decoded TX Antenna ID and Decoded TX Sector ID subfields, the DMG antenna index and sector index used by the responder to transmit the TDD SSW Feedback frame in the, respectively, TX Antenna ID and TX Sector ID subfields, and the SNR of the TDD SSW frame received with the best quality in the SNR Report subfield. The number of transmitted TDD SSW Feedback frames shall be equal to the value indicated in the Number of Requested Feedback subfield plus one of the received TDD SSW frame. The Feedback Count Index subfield in each transmitted TDD SSW Feedback frame shall contain the index of the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

TDD SSW Feedback frame transmitted in the same TDD slot, with the first TDD SSW Feedback frame having an index equal to 0. Except for the value of the Feedback Count Index subfield, all subfields of TDD SSW Feedback frames transmitted in a TDD slot shall have the same value of the corresponding field transmitted in the first TDD SSW Feedback frame within the TDD slot.

At the time offset indicated by Equation (10-21) of the decoded TDD SSW frame or, alternatively, during an assigned BF TDD slot, the responder shall set its receiver to the same DMG antenna and to the same sector that was indicated in the, respectively, TX Antenna ID and TX Sector ID subfields of the TDD SSW Feedback frame in order to be ready to receive a TDD SSW Ack frame from the initiator.

The responder shall continue sweeping through its receive sectors until successfully receiving and decoding a TDD SSW Ack frame with End of Training subfield equal to 1. Upon the reception of TDD SSW Ack frame with End of Training subfield equal to 1, the responder shall stop its receive sweeping and shall configure its DMG antenna as indicated in the Decoded TX Antenna ID subfield and its sector as indicated in the Decoded TX Sector ID subfield of the TDD SSW Ack frame received from the initiator that has the End of Training subfield equal to 1. The responder shall use this DMG antenna and sector for its subsequent frame exchange sequences with the initiator, until another sector is negotiated.

A responder that transmits a TDD SSW Feedback frame in response to a TDD SSW frame sent with End of Training subfield equal to 1 shall set the End of Training subfield in the TDD SSW Feedback frame to 1.

In the unscheduled TDD beamforming procedure, upon reception of a TDD SSW Ack frame with End of Training subfield equal to 1, the responder shall be ready to receive an Announce frame from the initiator at the time offset indicated by Equation (10-22). The responder shall then, at the time offset indicated by Equation (10-23), transmit an Announce or (Re)Association Request frame that includes a TDD Route element listing the ordered pairs of transmit sectors and decoded receive sectors obtained during the TDD beamforming training with the initiator. If necessary, the responder shall transmit additional frames at the periodic transmit opportunities following the time offset indicated by Equation (10-23), and shall be ready to receive additional frames at the periodic opportunities following the offset indicated by Equation (10-22).

In the scheduled TDD beamforming procedure, the responder shall send TDD SSW Feedback frames during BF TDD slots assigned to transmit from the responder to the initiator. The exchange of TDD Route elements takes place during Basic or Data TDD slots available to the initiator and the responder after completion of the TDD beamforming training.

A STA that has started to sweep its receive DMG antenna configuration in response to a TDD SSW frame with RA field set to the broadcast address and, during the same beamforming process, receives a TDD SSW frames with RA field set to an individual address different from the STA’s MAC address shall stop its receive sweeping and shall configure its DMG antenna to the sector as indicated in the last successful TDD beamforming or TDD sector switch procedure and shall use this sector for its subsequent frame exchanges with the initiator, until another sector is negotiated.

NOTE 3—Switching from group addressed to individual addressed TDD beamforming can be used as method to discover a new STA in vicinity. In this case, other responders remain connected and revert to previously negotiated sectors.

A non-AP and non-PCP responder that has a link in active state with the initiator and that has received a frame with a TDD Slot Structure element and a TDD Slot Schedule element shall sweep its receiver antenna configuration through its received sectors in BF TDD slots. The responder shall resume the sweep from the previous configuration (used in the preceding BF TDD slot, if any) at the beginning of each BF TDD slot regardless of the value of the Transmit Period subfield within a received TDD SSW frame. In this case, the SectorDwellTime should be set to TXTIME(TDD SSW)+SBIFS. Such a responder shall use a BF TDD slot assigned for transmission from the responder to the initiator to trasnsmit a TDD SSW Feedback frame using the best DMG antenna when receiving TDD SSW frames of the current BF TDD sector training. The

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

responder may set the End of Training subfield in the TDD SSW Feedback frame to indicate that it has received enough repetitions from the current transmit sector, so that the initiator may proceed to the next transmit sector. In this case, the initiator shall not set the End of Training subfield in the following TDD SSW Ack frame to 1.

10.41.11.4 Initiator operation for TDD group beamforming

For TDD group beamforming, the BFType parameter is set to TDD group BF in the MLME-TDD-BF-TRAINING.request primitive.

To initiate TDD group beamforming, the initiator shall send multiple TDD SSW frames. For each TDD SSW frame, the RA field shall be set to the broadcast address. The Responder ID subfield of each responder included in a transmitted TDD SSW frame is set to be the value derived from the responder's MAC address following the scheme depicted in Figure 10-132 (Generation of Responder ID subfield). The MAC address of each responder is indicated by the PeerSTAAddress parameter of the MLME-TDD-BF-TRAINING-START.request primitive.

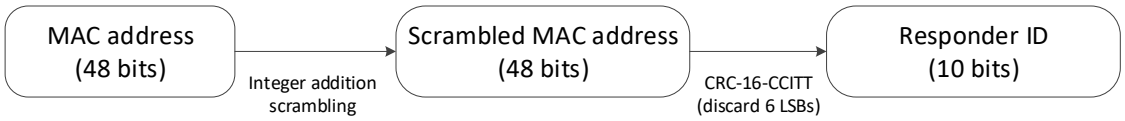

Figure 10-132—Generation of Responder ID subfield

The process starts by using the MAC address of the responder to generate the scrambled MAC address. The MAC address is divided into three words, $word_i$ ($0 \le i \le 2$), of 16 bits each, where $word_0$ is the 16 MSB of the MAC address and $word_2$ is the 16 LSB of the MAC address. For each $word_i$, a $scrambled\_word_i$ is created as follows:

$$scrambled\_word_i = (word_i + scramble\_pattern) \bmod 2^{16}$$

where

$word_i$ is the corresponding 16 bit word from the MAC address

scramble_pattern is $((0x5795 \times seed\_value) \bmod 2^{15})$, where *seed_value* is the value of the Scrambler Initialization field in the L-Header of the PPDU carrying the TDD SSW frame

The scrambled MAC address is generated by the consecutive concatenation of $scrambled\_word_0$, $scrambled\_word_1$, and $scrambled\_word_2$.

Finally, the Responder ID subfield is generated by taking the 10 MSBs of CRC-16-CCITT computed over the scrambled MAC address. The CRC-16 is computed as defined in 20.3.7 (HCS calculation for headers of DMG control mode and DMG SC mode).

TDD SSW frames that are sent from the same transmit DMG antenna shall have the same TX Antenna ID subfield value. TDD SSW frames that are sent from the same transmit sector shall have the same TX Sector ID subfield value. TDD SSW frames shall be transmitted at the same transmit power and shall not include BRP training fields.

An initiator shall send TDD SSW frames through all the DMG antennas and all the sectors indicated by the TX antenna index and TX sector index values contained in the TXAntennaSectorIDList parameter of the MLME-TDD-BF-TRAINING.request primitive. For each DMG antenna and each sector, the initiator shall send TDD SSW frames with the same TX Antenna ID and TX Sector ID subfield values for the number of times indicated in the NumOfTDDSlotPerTXSector parameter multiplied by the NumOfSSWPerTDDSlot

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

parameter of the MLME-TDD-BF-TRAINING.request primitive. If the initiator transmits a TDD SSW Ack frame, the initiator shall send as many TDD SSW Ack frames as the number indicated in the NumOfAckPerTDDSlot parameter of the MLME-TDD-BF-TRAINING.request primitive.

The Transmit Period subfield value within TDD SSW frames shall remain the same throughout a TDD beamforming training. If the value of the Transmit Period subfield is nonzero, at the time offset equal to the Transmit Period subfield value the initiator shall transmit a TDD SSW frame or a TDD SSW Ack frame of the TDD beamforming training with the same Count Index value.

TDD SSW and TDD SSW Ack frames transmitted in the same TDD slot shall be be separated with SBIFS and shall have a strictly increasing Count Index subfield value, with the first transmitted TDD SSW frame or TDD SSW Ack frame in a TDD slot having this subfield equal to 0.

To receive a TDD SSW Feedback frame from the responder, the initiator shall set its receive DMG antenna to the same DMG antenna and sector as was indicated, respectively, in the TX Antenna ID and TX Sector ID subfields of the respective TDD SSW frame, at the following offset from the end of the last transmitted TDD SSW frame:

$$ResponderFeedbackOffset_n - [AckCountIndex \times \text{TXTIME(TDD SSW Ack)} + (CountIndex + 1 - AckCountIndex) \times \text{TXTIME(TDD SSW)} + (CountIndex \times \text{SBIFS})] \quad (10\text{-}24)$$

where

$ResponderFeedbackOffset_n$ is the value of the Responder Feedback Offset subfield in the n^{th} responder's Responder Info subfield of the TDD SSW frame with the same TX Sector ID within the same TDD slot

CountIndex and *AckCountIndex* are, respectively, the values of the Count Index and Ack Count Index subfields in the transmitted TDD SSW frame

In order to avoid collision of TDD SSW Feedback frames, different Responder Feedback Offset subfield values in the Responder Info subfield of the TDD SSW frame should be used for different responders.

Figure 10-133 (TDD SSW Feedback frame transmit time for unscheduled TDD group BF) depicts the calculation of time to transmit a TDD SSW Feedback frame for unscheduled TDD group BF.

If the initiator received a TDD SSW Feedback frame, it shall transmit one or more TDD SSW Ack frames to the responder that sent the TDD SSW Feedback frame. To transmit the frames to this responder the initiator shall set its antennas to the Decoded TX Sector ID and the Decoded TX Antenna ID from the last TDD SSW Feedback frame received from this responder. The transmission of the first TDD SSW Ack frame shall start at the following offset calculated as a spacing from the end of the transmitted TDD SSW frame to the start of the transmission of the first TDD SSW Ack frame to the responder that sent the TDD SSW Feedback frame:

$$InitiatorAckOffset_n - [AckCountIndex \times \text{TXTIME(TDD SSW Ack)} + (CountIndex + 1 - AckCountIndex) \times \text{TXTIME(TDD SSW)} + (Count\ Index \times \text{SBIFS})] \quad (10\text{-}25)$$

where

$InitiatorAckOffset_n$ is the value of the Initiator Ack Offset subfield in the n^{th} responder's Responder Info subfield of the TDD SSW frame with the same TX Sector ID within the same TDD slot

CountIndex and *AckCountIndex* are, respectively, the values of the Count Index and Ack Count Index subfields in the transmitted TDD SSW frame

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

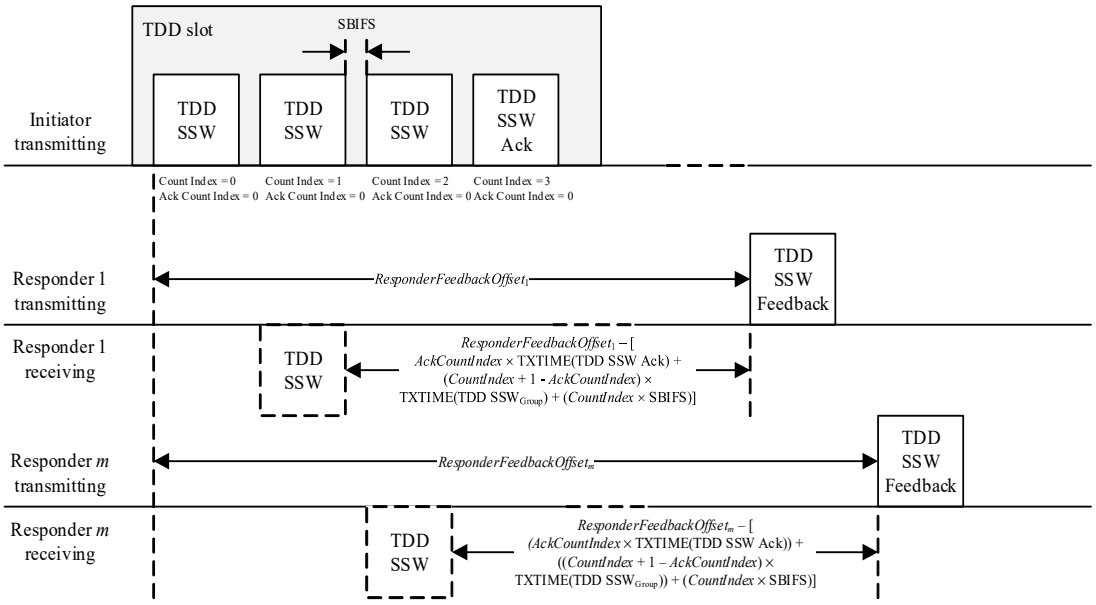

Figure 10-133—TDD SSW Feedback frame transmit time for unscheduled TDD group BF

The TDD SSW Ack frame shall include the DMG antenna and sector used by the responder to transmit the TDD SSW Feedback frame in, respectively, the Decoded TX Antenna ID and Decoded TX Sector ID subfields, the measured SNR of the decoded TDD SSW Feedback frame in the SNR Report subfield and, when performing unscheduled TDD beamforming, time offsets to exchange frames containing TDD Route, TDD Slot Structure, and TDD Slot Schedule elements.

For TDD group BF, an initiator may request one or more responders to stop their receive sector sweeping by setting the End of Training subfield to 1 in the Responder Info subfield corresponding to each responder in a transmitted TDD SSW frame. Upon reception of a TDD SSW Feedback frame with the End of Training subfield equal to 1 from a responder, the initiator shall send one or more TDD SSW Ack frames to the corresponding responder with the End of Training subfield set to 1 at the time offset indicated by Equation (10-25) or, alternatively, at a TDD slot allocated via the TDD Slot Schedule element. The initiator may also set the End of Training subfield in SSW Ack frames to 1 even if the End of Training subfield in a received TDD SSW Feedback frame was not set to 1. After sending a TDD SSW Ack frame with End of Training subfield equal to 1, the initiator shall configure its receive and transmit DMG antenna and sector index as indicated in the Decoded TX Antenna ID and Decoded TX Sector ID subfields of the TDD SSW Feedback frame received from the corresponding responder in which its End of Training subfield was set to 1. The initiator shall use this DMG antenna and sector for its subsequent transmissions and receptions with the corresponding responder, until another sector is negotiated.

The length of a TDD SSW frame shall remain the same during TDD group beamforming. For each target responder that has completed TDD beamforming training, the corresponding Responder Info Valid subfield shall be set to 0 to indicate an invalid Responder Info subfield.

Once the initiator sends a TDD SSW Ack frame with the End of Training subfield equal to 1 to a target responder, it may transmit a single PPDU other than a TDD Beamforming frame to the target responder. To transmit this frame, the initiator shall set its transmit DMG antenna and sector to the Decoded TX Antenna ID and the Decoded TX Sector ID from the TDD SSW Feedback frame last received from the target responder. The transmission of the frame shall start at the following offset calculated as a spacing from the end of the last transmitted SSW Ack frame with the End of Training subfield set to 1 to the start of the expected transmission:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

$$InitiatorTransmitOffset - [(AckCountIndex + 1) \times \text{TXTIME(TDD SSW Ack)} + (CountIndex - AckCountIndex) \times \text{TXTIME(TDD SSW)} + (Count\ Index \times \text{SBIFS})] \quad (10\text{-}26)$$

where

InitiatorTransmitOffset is the value of the Initiator Transmit Offset subfield in the TDD SSW Ack frame with the End of Training subfield set to 1

CountIndex is the value of the Count Index subfield in the received TDD SSW or TDD SSW Ack frame

AckCountIndex is the value of the Ack Count Index subfield in the transmitted TDD SSW Ack frame

Subsequent opportunities for the initiator to transmit to the responder are separated by the value of the Transmit Period subfield in the TDD SSW Ack frame with the End of Training subfield set to 1.

After the initiator has sent the last TDD SSW Ack frame with the End of Training subfield equal to 1 to a target responder, it shall be ready to receive a single PPDU other than a TDD Beamforming frame from the responder, by setting its receive DMG antenna and sector to the Decoded TX Antenna ID and the Decoded TX Sector ID and from the TDD SSW Feedback frame last received from the responder, and at the following offset calculated as a spacing from the end of the transmitted TDD SSW Ack frame with the End of Training subfield set to 1 to the start of the expected reception:

$$ResponderTransmitOffset - [(AckCountIndex + 1) \times \text{TXTIME(TDD SSW Ack)} + (CountIndex - AckCountIndex) \times \text{TXTIME(TDD SSW)} + (Count\ Index \times \text{SBIFS})] \quad (10\text{-}27)$$

where

ResponderTransmitOffset is the value of the Responder Transmit Offset subfield in the TDD SSW Ack frame with the End of Training subfield set to 1

CountIndex is the value of the Count Index subfield in the respective TDD SSW or TDD SSW Ack frame

AckCountIndex is the value of the Ack Count Index subfield in the transmitted TDD SSW Ack frame

Subsequent opportunities for the responder to transmit to the initiator are separated by the value of the Transmit Period subfield in the TDD SSW Ack frame with the End of Training subfield set to 1.

For the unscheduled TDD beamforming procedure, Equation (10-24) and Equation (10-25) establish transmit opportunities to exchange TDD Beamforming frames, and Equation (10-26) and Equation (10-27) establish transmit opportunities to exchange frames other than TDD Beamforming frames after TDD beamforming training completion with the target responder.

In the unscheduled TDD beamforming procedure, upon transmission of the last TDD SSW Ack frame with End of Training subfield equal to 1, the initiator shall follow the same procedure as the initiator in 10.41.11.2 (Initiator operation for TDD individual beamforming) with *InitiatorTransmitOffset* and *ResponderTransmitOffset* parameters given by Equation (10-26) and Equation (10-27) instead of Equation (10-22) and Equation (10-23).

In the scheduled TDD beamforming procedure, the initiator shall send TDD SSW and TDD SSW Ack frames during BF TDD slots assigned to transmit from the initiator to the responder. The exchange of TDD Route elements takes place during nonbeamforming TDD slots available to the initiator and the target responder after completion of the TDD beamforming training with the target responder.

10.41.11.5 Responder operation for TDD group beamforming

A responder STA that is in inactive state (see 11.54 (TDD channel access operation)) or has not yet received a TDD SSW frame or has not yet acquired a TDD Slot Structure element used by the BSS shall sweep its receiver antenna through all its receive sectors while dwelling on each sector for a time equal to SectorDwellTime as indicated by the MLME-TDD-BF-SCAN.request primitive.

NOTE—To increase the likelihood of detecting an initiator's TDD SSW frame, the responder SME can set SectorDwellTime to at least [2 × TXTIME (TDD SSW) + SBIFS].

A responder STA that receives a TDD SSW frame with a Responder ID subfield that matches its ID shall sweep its receiver antenna configuration through its receive sectors between TDD beamforming frames received in a TDD slot and shall switch its receive sectors at the beginning of every TDD slot used for BF training according to the time interval indicated by a nonzero Transmit Period subfield value of the received TDD SSW frame.

Figure 10-134 (Responder's receiver sweeping for TDD group BF) gives an example of the responder's receiver sweeping procedure for TDD group BF.

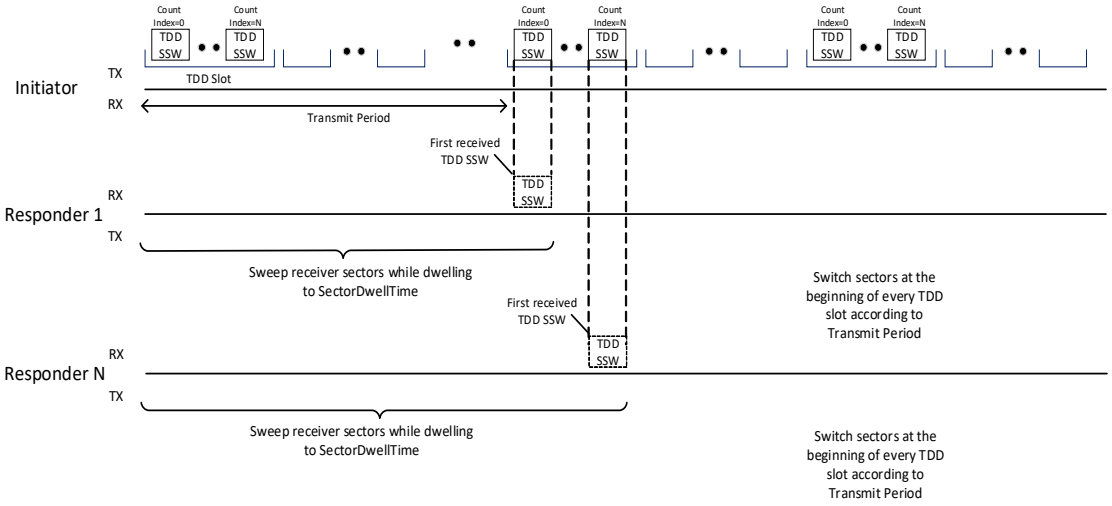

Figure 10-134—Responder's receiver sweeping for TDD group BF

Once the first TDD SSW frame is received, the responder proceeds with the following operation.

Upon reception of one or more TDD SSW frames on a receive sector, the responder may switch, within the TDD slot, to its next receive sector to be ready to receive the next TDD SSW frame transmission within SBIFS. The responder shall switch its receive sector at the beginning of every TDD slot used for BF training at the time specified by the Transmit Period subfield value in the received TDD SSW frame. While sweeping through its receive sectors, the responder shall continue decoding all the received TDD SSW frames.

The responder shall transmit a TDD SSW Feedback frame using the DMG antenna and sector from which the responder received the TDD SSW with the best link quality at the time indicated by Equation (10-24) in case of unscheduled TDD beamforming or, alternatively, at an assigned BF TDD slot. The TDD SSW Feedback frame shall include the DMG antenna and sector index used by the initiator to transmit the TDD SSW frame in, respectively, the Decoded TX Antenna ID and Decoded TX Sector ID subfields, the antenna

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

index and sector index used by the responder to transmit the TDD SSW Feedback frame in, respectively, the TX Antenna ID and TX Sector ID subfields, and the SNR of the TDD SSW frame received with the best quality in the SNR Report subfield.

At the time offset indicated by Equation (10-25) of the decoded TDD SSW frame or, alternatively, at an assigned BF TDD slot, the responder shall set its receiver to the same DMG antenna index and to the same sector that was indicated in, respectively, the TX Antenna ID and TX Sector ID subfields of the TDD SSW Feedback in order to be ready to receive a TDD SSW Ack frame from the initiator.

The responder shall continue sweeping through its receive sectors until successfully receiving and decoding a TDD SSW Ack frame with End of Training subfield equal to 1. Upon the reception of a TDD SSW Ack frame with End of Training subfield equal to 1, the responder shall stop its receive sweeping and shall configure its DMG antenna and sector as indicated in, respectively, the Decoded TX Antenna ID and Decoded TX Sector ID subfields of the TDD SSW Ack frame received from the initiator that has the End of Training subfield equal to 1. The responder shall use this DMG antenna and sector for its subsequent frame exchange sequences with the initiator, until another sector is negotiated.

A responder that transmits a TDD SSW Feedback frame in response to a TDD SSW frame sent with End of Training subfield equal to 1 shall set the End of Training subfield in the TDD SSW Feedback frame to 1.

In the unscheduled TDD beamforming procedure, upon reception of a TDD SSW Ack frame with End of Training subfield equal to 1, the responder, at the time offset indicated by Equation (10-27), shall follow the same procedure as the responder in 10.41.11.3 (Responder operation for TDD individual beamforming) with *InitiatorTransmitOffset* and *ResponderTransmitOffset* parameters given by Equation (10-26) and Equation (10-27) instead of Equation (10-22) and Equation (10-23).

In the scheduled TDD beamforming procedure, the responder shall send TDD SSW Feedback frames during BF TDD slots assigned to transmit from the responder to the initiator. The exchange of TDD Route elements takes place during Basic or Data TDD slots available to the initiator and the responder after completion of the TDD beamforming training.

10.41.11.6 Initiator operation for TDD beam measurement

The initiator operation during a TDD beam measurement is the same as the initiator operation for TDD individual BF, with the following differences:

— TDD beam measurement is started upon receiving an MLME-TDD-BEAM-MEASUREMENT.request primitive with BFRole parameter set to Initiator.
— The Initiator may send an Announce frame to a responder containing a TDD Route element with a TDD Sector Config subelement indicating the RX Sectors ID and RX Antenna ID to be used by the responder in the TDD beam measurement.
— During a TDD beam measurement, the TDD Slot CDOWN field in each transmitted frame shall contain the total number of BF TDD slots remaining until the end of the initiator TDD beam measurement, such that the last TDD SSW frame transmission by the initiator has the TDD Slot CDOWN field equal to 0.
— The initiator may set the Feedback Requested subfield in the TDD Beamforming Information field to 1 to request that the responder(s) send, following the completion of the TDD beam measurement, an Announce frame with a TDD Route element containing the measurement results.
— No TDD SSW Ack frame shall be transmitted.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

10.41.11.7 Responder operation for TDD beam measurement

The responder operation during a TDD beam measurement procedure is the same as the responder operation for TDD individual BF, with the following differences:

— TDD beam measurement is started upon receiving an MLME-TDD-BEAM-MEASUREMENT.request primitive with BFRole parameter set to Responder, or by receiving a TDD SSW frame with the RA field equal to STA's MAC address or the broadcast address, and with the TDD Beam Measurement field set to 1.

— If a TDD Sector Config subelement was received for this TDD beam measurement, the responder shall utilize the RX Sectors ID and RX Antenna ID configurations as indicated in the TDD Sector Config subelement.

— If the Feedback Requested subfield in a TDD SSW frame received by the responder is 0, the responder shall not transmit any frames to the initiator and shall report the measurement results to the SME instead.

— If the Feedback Requested subfield in a TDD SSW frame received by the responder is 1, the responder shall send an Announce frame with a TDD Route element containing the results of the TDD beam measurement on all received sectors. The Announce frame shall be sent in the first TDD slot allocated for transmission from the responder to the initiator.

— TDD beam measurement ends at the end of the TDD slot during which the initiator transmits the last TDD SSW frames with the TDD Slot CDOWN field equal to 0.

10.42 DMG link adaptation

10.42.1 General

A STA may transmit a Link Measurement Request frame to request a STA indicated in the RA field of the frame to respond with a single Link Measurement Report frame or periodic Link Measurement Report frames (9.6.6.5). If the Link Measurement Request frame is sent within a PPDU defined in Clause 20 or Clause 28, the Link Measurement Report frame shall contain the DMG Link Margin element. If the DMG Link Margin element does not include the PPDU Statistics field, nor the LDPC Statistics field and nor the SC/OFDM Statistics field, the requesting STA may use values of the MCS, SNR and Link Margin fields in a received DMG Link Margin element to transmit frames to the STA indicated in the RA field of the Link Measurement Request frame. Otherwise, the requesting STA may use values of the MCS, SNR and Link Margin field(s) in the received PPDU Statistics field to transmit frames to the STA indicated in the RA field of the Link Measurement Request frame.

The Number of Space-Time Streams Reported (NSTS) field in a DMG Link Margin element shall be set to the number of space-time streams received.

If the Link Measurement Request frame is sent within a PPDU defined in Clause 28, the Number of Transmit Chains Reported (NTX) field in the DMG Link Margin element within the Link Measurement Report frame shall be set to the same value indicated in the Extended TPC Configuration subelement within the Link Measurement Request frame. In this case, the requesting STA may use the reported MCS, SNR, and link margin values when transmitting frames to the STA indicated in the RA field of the Link Measurement Request frame using multiple transmit chains.

The requesting STA may aggregate a Link Measurement Request frame in an A-MPDU as defined in Table 9-661 and Table 9-663.

To initiate a periodic link measurement with a peer STA, the requesting STA shall transmit a Link Measurement Request frame to the peer STA that includes the Periodic Report Request subelement. The requesting STA should transmit at least one Management or Data frame (e.g., a QoS Null frame) to the peer

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

STA, preferably requiring acknowledgment, every interval of time indicated by the value of the Report Interval field within the Periodic Report Request subelement to keep the statistics reported in the periodic Link Measurement Report frames transmitted by the peer STA updated.

If the Dialog Token field in the Link Measurement Request frame is nonzero, the responding STA shall perform the measurement on the next frame received from the requesting STA and shall send back a Link Measurement Report frame corresponding to the received frame. If the Link Measurement Request frame includes the Periodic Report Request subelement and the responding STA accepts a periodic link measurement request, at the time indicated by the value of the Report Start Time subfield, the responding STA shall send at least one Link Measurement Report frame including the Periodic Report subelement to the requesting STA for each report interval. The transmission of at least one unsolicited Link Measurement Report frame should be as close as possible to the start of each consecutive report interval subject to channel access rules. The total number of report intervals shall be equal or smaller than the value of the Report Count subfield in the Link Measurement Request frame. If the Link Measurement Request frame includes the Periodic Report Request subelement and the responding STA rejects a periodic link measurement request, the responding STA shall transmit a Link Measurement Report frame and set the Accept/Reject Periodic Report subfield within the Periodic Report Control field of the Periodic Report subelement to 0.

The responding STA may aggregate a Link Measurement Report frame in an A-MPDU as defined in Table 9-661 and Table 9-663.

The DMG STA whose MAC address equals the value of the Link Measurement Request frame RA field shall transmit one or more Link Measurement Report frame addressed to the requesting STA. The RA field of the Link Measurement Report frame shall be equal to the TA field of the Link Measurement Request frame.

If the Dialog Token field in the Link Measurement Report frame is equal to the nonzero Dialog Token field of the Link Measurement Request frame, then the MCS, SNR, and Link Margin fields of the Link Measurement Report frame shall be computed using the measurements of the PPDU that is the next frame received from the requesting STA, or the PPDUs received from the requesting STA within the corresponding report interval and subject to the reset condition rules (see 9.4.2.141.6). The DMG Link Margin element within the Link Measurement Report frame shall include the following:

— The RX Chain Statistics field if the Number of RX Chains Reported (NRX) subfield in the Rate Adaptation Control/Extended TPC field is greater than 0.
— The PPDU Statistics field if the PPDU Statistics Present subfield in the Rate Adaptation Control/ Extended TPC field is 1.
— The LDPC Statistics field if the LDPC Statistics Present subfield in the Rate Adaptation Control/ Extended TPC field is 1.
— The SC/OFDM Statistics field if the SC/OFDM Present subfield in the Rate Adaptation Control/ Extended TPC field is 1.

The DMG Link Margin element should not include the RX Chain Statistics, PPDU Statistics, LDPC Statistics and SC/OFDM Statistics fields if the Number of PPDUs subfield in the Rate Adaptation Control/ Extended TPC field is 0.

NOTE—The MCS, SNR, and link margin values can be carried in either the three similarly named fields in the Link Measurement Report frame, or as part of the PPDU Statistics field in the same frame.

If the Dialog Token field in the Link Measurement Request frame is equal to 0, the responding STA may set the MCS field in the Link Measurement Report frame to the MCS value computed based on any of the received frames from the requesting STA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The SNR field and Link Margin field in the Link Measurement Report frame shall indicate the corresponding measurements based on the reception of the PPDU that was used to generate the MCS feedback contained in the same Link Measurement Report frame. If the Link Measurement Report frame contains measurements of more than one STS, the SNR subfield in the PPDU Statistics field and the Link Margin subfield in the Extended TPC field in the Link Measurement Report frame shall indicate the corresponding measurements based on the reception of the PPDU that was used to generate the MCS feedback contained in the PPDU Statistics field within the same Link Measurement Report frame, or the corresponding measurements of PPDUs received from the requesting STA within the corresponding report interval and subject to the reset condition rules (see 9.4.2.141.6).

The Link Measurement Request and Report frames can be used to obtain link margin information, which can be used to determine appropriate action by the requesting STA (e.g., change MCS or control transmit power or initiate FST).

A STA may send an unsolicited Link Measurement Report frame with the Dialog Token field set to 0.

10.42.2 DMG TPC

A DMG STA that receives a Link Measurement Report frame containing a DMG Link Margin element that indicates increase or decrease transmit power behaves according to the following rules:

— If the STA implements the recommendation indicated in the Activity field of the Link Measurement Report frame that does not include a Rate Adaptation Control/Extended TPC field, it shall send a Link Measurement Report frame containing a DMG Link Adaptation Acknowledgment element. The Activity field of the DMG Link Adaptation Acknowledgment element shall be set to the value of the Activity field in the received DMG Link Margin element.

— If the STA does not implement the recommendation indicated in the Activity field of the Link Measurement Report frame that does not include a Rate Adaptation Control/Extended TPC field, it may send a Link Measurement report containing a DMG Link Adaptation Acknowledgment element. The Activity field of the DMG Link Adaptation Acknowledgment element shall be set to 0.

— A STA shall not send a Link Measurement Report later than 2×aPPDUMaxTime after it acknowledged the reception of the Link Measurement report.

— If the STA implements the recommendation indicated in the Extended Activity field of a Link Measurement Report frame that includes a Rate Adaptation Control/Extended TPC field for one or more STS, it shall send a Link Measurement Report frame containing a DMG Link Adaptation Acknowledgment element. The value of the Number of STS Reported field within the DMG Link Adaptation Acknowledgment element shall be set to the same value of the Number of STS Reported field in the DMG Link Margin element within the Link Measurement Report frame. If the STA implements the recommendation for an STS, the Extended Activity acknowledgment field of the DMG Link Adaptation Acknowledgment element shall be set to the value of the Extended Activity field in the received DMG Link Margin element of the same STS. If the STA does not implement the recommendation for an STS, the Activity field of the DMG Link Adaptation Acknowledgment element shall be set to 0. In addition, the Extended Activity acknowledgment Parameter value shall be set to the actual transmit power change that the STA implements, using the same encoding as the transmit power change request (see 9.4.2.141.8).

A DMG STA shall not include the DMG Link Adaptation Acknowledgment element in a Link Measurement Report frame, unless the frame is being transmitted in response to a Link Measurement Report frame whose Activity field is equal to increase or decrease transmit power.

10.42.3 Fast link adaptation

A STA indicates support for fast link adaptation by setting the Fast Link Adaptation field in the STA's DMG Capabilities element to 1. A STA that does not support fast link adaptation sets the Fast Link Adaptation

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

field in the STA's DMG Capabilities element to 0. A STA that supports fast link adaptation shall not initiate fast link adaptation with a peer STA that does not support fast link adaptation.

A STA that supports fast link adaptation shall support the reverse direction protocol (see 10.29). The STA that transmits a Link Measurement Request frame as part of fast link adaptation shall be the RD initiator and the STA that responds with a Link Measurement Report frame shall be the RD responder. Transmission of Link Measurement Request, Link Measurement Report and the frames defined below shall follow the rules of the reverse direction protocol.

A STA initiates fast link adaptation by transmitting a Link Measurement Request frame that is of subtype Action No Ack and has its Dialog Token field set to 0. The PPDU containing the frame shall have the AGGREGATION parameter in the TXVECTOR set to AGGREGATED, shall not contain any other frame that requires immediate response, and shall have a duration (as determined by the PLME-TXTIME.confirm primitive defined in 6.7.6) that is greater than aMinPPDUDurationForDMGMeasurement.

NOTE—The PPDUs have the AGGREGATION parameter in the TXVECTOR set to AGGREGATED to allow padding of the PSDUs with MPDU delimiters of size 0, therefore meeting the transmission duration requirement.

A STA that supports fast link adaptation and receives a Link Measurement Request frame of subtype Action No Ack, with the Dialog Token field equal to 0 and contained in a PPDU with the AGGREGATION parameter in the RXVECTOR equal to AGGREGATED shall respond with a Link Measurement Report frame in no longer than BRPIFS from the reception of the Link Measurement Request frame. The TPC Report element, DMG Link Margin element and other fields transmitted in the Link Measurement Report frame shall reflect measurements on the PPDU that contained the last received Link Measurement Request frame from the initiating STA.

The STA responding with the Link Measurement Report frame shall keep the IFS not longer than SIFS by transmitting PPDUs that do not contain frames requiring immediate response and that have a duration that is greater than aMinPPDUDurationForDMGMeasurement. All transmitted PPDUs should use the same MCS and the same transmit power.

The transmitted Link Measurement Report frame shall be of subtype Action No Ack, shall be sent using MCS 1, and shall be sent within a PPDU with the AGGREGATION parameter in the TXVECTOR set to AGGREGATED. In addition, the PPDU shall not contain any frame that requires immediate response and shall have a duration that is greater than aMinPPDUDurationForDMGMeasurement.

If at least one of the conditions above for the transmission of the Link Measurement Report frame is not met, the STA may follow the rules in 10.42.1 to respond to the received Link Measurement Request frame.

A STA that supports fast link adaptation and that receives a Link Measurement Report frame should respond with an unsolicited Link Measurement Report frame in no longer than BRPIFS from the reception of the Link Measurement Report frame. The TPC Report element, DMG Link Margin element and other fields transmitted in the unsolicited Link Measurement Report frame shall reflect measurements taken on one or more of the PPDUs received by the STA transmitting the unsolicited Link Measurement Report frame, starting with the received Link Measurement Report frame itself. If the unsolicited Link Measurement Report frame is transmitted longer than SIFS from the reception of the Link Measurement Report frame, the STA transmitting the unsolicited Link Measurement Report frame shall keep the IFS not longer than SIFS by transmitting one or more PPDUs before issuing the unsolicited Link Measurement Report frame.

An example of the fast link adaptation procedure is shown in Figure 10-135 (Example of fast link adaptation procedure).

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

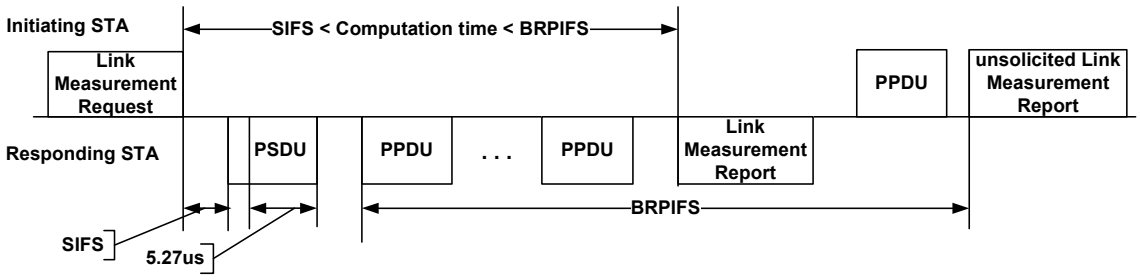

Figure 10-135—Example of fast link adaptation procedure

10.42.4 EDMG spatial stream feedback

An EDMG STA may provide feedback on individual transmitted spatial streams by appending a control trailer (see 10.38.12.5 (Control trailer)) to SSW-Feedback, BlockAck or Ack frames. Spatial stream feedback information may be used for MCS selection or to trigger beamforming between STAs.

To do this, the STA shall set the TXVECTOR parameter SCRAMBLER_INIT_SETTING to CONTROL_TRAILER, shall set the TXVECTOR parameter CT_TYPE to SSW_FEEDBACK in case of transmitting an SSW-Feedback frame, to BLOCK_ACK in case of transmitting a BlockAck frame, or to ACK in case of transmitting an Ack frame. The STA shall set the TXVECTOR parameter STREAM_FBCK to contain the per spatial stream feedback.

The per stream SNR and RSSI information in the control trailer shall be measured by the STA during the reception of the PPDU immediately before the corresponding SSW-Feedback, BlockAck or Ack frame is transmitted.

10.42.5 TDD link maintenance

A STA indicates support for TDD link maintenance by setting the TDD Link Maintenance Statistics field within the STA's DMG Capabilities element to a nonzero value. A STA that supports TDD link maintenance shall not initiate TDD link maintenance, as specified below, with a peer STA that does not support TDD link maintenance.

The SME of the STA that supports TDD link maintenance shall use the PLME-MINPAYLOADSTAT.request primitive to request the PHY to initiate measurement of signal power of received PPDUs and to compute the receiver statistics as described below. Upon receiving a PLME-MINPAYLOADSTAT.request primitive, the PHY shall use the parameter PSDU_MIN_LENGTH of the primitive to start the measurements and shall respond to the MAC with a PLME-MINPAYLOADSTAT.confirm primitive.

A STA that supports TDD link maintenance and that receives a Link Measurement Request frame shall include a DMG Link Margin element in a transmitted Link Measurement Report frame. The STA shall perform the link statistics measurements and set the DMG Link Margin element according to the following rules:

— In the RX Chain Statistics field, the RCPI shall be measured during the reception of the L-STF or EDMG-STF field of the PPDU. The measurement shall be performed on the same bandwidth as the PSDU.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The value of the PPDU Statistics field is computed as follows:
  — For an SC mode PPDU, the SNR per stream is found by computing the SNR of the DMG or EDMG preambles. If EDMG preambles are present, it shall be used to compute the SNR. The measurement shall be on the same bandwidth as the PSDU.
  — For an OFDM mode PPDU, the average SNR per stream is found by computing the SNR per subcarrier in decibels for all the pilot and data subcarriers, and then computing the arithmetic mean of those values. Each SNR value per subcarrier and per stream (before being averaged) corresponds to the SNR of one of the pilot or data subcarrier. The SNR value per subcarrier per stream shall be based on measurement of EDMG-STF and/or EDMG-CEF using the same bandwidth as the PSDU.
— To compute the value of the LDPC Statistics field, the PPDUs used for computing the Average Iterations, Max Iteration, Nonzero Syndromes and Number of LDPC Codewords subfields are those PPDUs that have the payload length greater or equal to PSDU_MIN_LENGTH. All reported LDPC statistics shall be measured over the PSDU of a PPDU.
— To compute the value of the SC/OFDM Statistics field, the PPDUs used for computing the EVM and Number of SC Blocks/OFDM Symbols subfields are those PPDUs that have the payload length greater or equal to PSDU_MIN_LENGTH. The EVM is computed by averaging, in power units, the estimated EVM of SC data symbols or OFDM data subcarriers across PSDUs of PPDUs transmitted with an MCS different from MCS 0. The average is performed per space-time stream. The EVM estimation per SC symbol or OFDM carrier should be as close as possible to the value computed when the estimator has full knowledge of the transmitted signal.

When the following reset condition is met, the statistics specified in 9.4.2.141.4, 9.4.2.141.5, 9.4.2.141.6, and 9.4.2.141.7 shall be reset:

— Any change of modulation (SC or OFDM), MCS, constellation, LDPC mode, GI/CP length, number of space-time streams, or MIMO type, or
— The number of reports sent reaches the value of the Report Count subfield in the Periodic Report Request subelement (see 9.4.2.288.2) associated with this measurement.

To cause the PHY to stop performing measurements over received PPDUs, the SME shall invoke the PLME-MINPAYLOADSTATSTOP.request primitive.

10.42.6 Extended TPC

A DMG STA supports the extended TPC mechanism specified in this subclause if the Extended TPC Rx Supported subfield in the STA's last transmitted DMG Capabilities element is 1. A STA that supports the extended TPC shall support TDD link maintenance as defined in 10.42.5 (TDD link maintenance) and periodic link measurement as defined in 10.42.1 (General).

A STA that has dot11ExtendedTPCActivated set to Rx and that receives a Link Measurement Report frame shall adjust its transmit power according to the values indicated by the Extended TPC field within the DMG Link Margin element carried in the received Link Measurement Report frame. A STA is not required to adjust its transmit power if the value exceeds the STA capabilities.

NOTE 1—A STA that has dot11ExtendedTPCActivated set to Rx sends a Link Measurement Request frame to a peer STA with an Extended Link Measurement element that includes a Periodic Report Request subelement. As such, the STA periodically receives a Link Measurement Report frame that includes the Extended TPC subfield with a transmit power update. The STA uses the received values to update its transmitter power. The peer STA, which responds with a Link Measurement Report frame, continuously evaluates the link based on the information it receives from the STA and computes the transmit power update for the STA.

A STA that has dot11ExtendedTPCActivated set to Tx and that receives s Link Measurement Report frame shall adjust its transmit power. The algorithm to determine the transmit power adjustment is beyond the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

scope of this standard. The STA may use any part of received measurements and any additional information available to the STA.

NOTE 2—A STA that has dot11ExtendedTPCActivated set to Tx sends a Link Measurement Request frame to a peer STA with an Extended Link Measurement element that includes a Periodic Report Request subelement. As such, the STA periodically receives a Link Measurement Report frame that includes at least one of the RX Chain Statistics, PPDU Statistics, LDPC Statistics, or SC/OFDM Statistics fields. The STA uses the received values to update its transmitter power. The STA might also receive an Extended TPC subfield, including a transmit power update. When dot11ExtendedTPCActivated is equal to Tx, the STA is not required to adopt the values in Extended TPC subfield; the STA can use these values as additional information to update its transmitter power.

An AP or PCP that has dot11ExtendedTPCActivated set to Tx or Rx shall have Extended TPC Rx Supported subfield in its DMG Capabilities element set to 1, as well as support the computation and report of the Extended TPC field defined in 9.4.2.141.8.

10.43 Link adaptation using the CMMG link measurement

10.43.1 General

A STA may transmit a Link Measurement Request frame to request a STA indicated in the RA field of the frame to respond with a Link Measurement Report frame (9.6.6.5) in SC transmission. If the Link Measurement Request frame is sent within a PPDU defined in Clause 25, the Link Measurement Report frame shall contain the CMMG Link Margin element. The requesting STA may use values of the MCS, of the SNR, and of the link margin to transmit frames to the STA indicated in the RA field of the Link Measurement Request frame.

The requesting STA may aggregate a Link Measurement Request frame in an A-MPDU as defined in Table 9-661 and Table 9-663.

If the Dialog Token field in the Link Measurement Request frame is nonzero, the responding STA shall perform the measurement on the next frame received from the requesting STA and shall send back a Link Measurement Report frame corresponding to the received frame.

The responding STA may aggregate a Link Measurement Report frame in an A-MPDU as defined in Table 9-661 and Table 9-663.

A CMMG STA with MAC address that is equal to the value of the Link Measurement Request frame RA field shall transmit a Link Measurement Report frame addressed to the requesting STA. The RA field of the Link Measurement Report frame shall be equal to the TA field of the Link Measurement Request frame.

If the Dialog Token field in the Link Measurement Report frame is equal to the nonzero Dialog Token field of the Link Measurement Request frame, the MCS, SNR, and Link Margin fields of the Link Measurement Report frame shall be computed using the measurements of the PPDU that is the subsequent frame following the Link Measurement Request frame.

If the Dialog Token field in the Link Measurement Request frame is equal to 0, the responding STA may set the MCS field in the Link Measurement Report frame to the MCS value computed based on any of the received frames from the requesting STA.

The SNR field and Link Margin field in the Link Measurement Report frame shall indicate the corresponding measurements based on the reception of the PPDU that was used to generate the MCS feedback contained in the same Link Measurement Report frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The Link Measurement Request and Link Measurement Report frames can be used to obtain link margin information, which can be used to determine appropriate action by the requesting STA (e.g., change MCS or control transmit power or initiate FST).

A STA may send an unsolicited Link Measurement Report frame with the Dialog Token field set to 0.

10.43.2 CMMG TPC

A CMMG STA that receives a Link Measurement Report frame containing a CMMG Link Margin element that indicates Increase or Decrease Transmit power behaves according to the following rules:

— If the CMMG STA intends to implement the recommendation indicated in the Activity field of the Link Measurement Report frame, it shall implement the change and send a Link Measurement Report containing a CMMG Link Adaptation Acknowledgment element not later than 2×aPPDUMaxTime after it acknowledged the reception of the Link Measurement Report frame. The Activity field of the CMMG Link Adaptation Acknowledgment element shall be set to the value of the Activity field in the received CMMG Link Margin subelement.

— If the CMMG STA does not implement the recommendation indicated in the Activity field of the Link Measurement Report frame, it may send the Link Measurement report containing a CMMG Link Adaptation Acknowledgment element no later than 2×aPPDUMaxTime after it acknowledges the reception of the Link Measurement Report frame. The Activity field of the CMMG Link Adaptation Acknowledgment element shall be set to 0, indication the STA prefers to not change transmit power.

A CMMG STA shall not include the CMMG Link Adaptation Acknowledgment element in a Link Measurement Report frame unless it is in response to a Link Measurement Report with the Activity field set to increase or decrease transmit power.

10.43.3 CMMG fast link adaptation

A CMMG STA supports fast link adaptation if the Fast Link Adaptation field in the STA's CMMG Capabilities Info field is 1. Otherwise, the STA does not support fast link adaptation. A STA that supports fast link adaptation shall not use fast link adaptation with a peer STA that does not support fast link adaptation.

A STA that supports fast link adaptation shall support the reverse direction protocol (see 10.29).

The STA that transmits a Link Measurement Request frame as part of fast link adaptation shall be the RD initiator, and the STA that responds with a Link Measurement Report frame shall be the RD responder. Transmission of Link Measurement Request frame, Link Measurement Report frame, and the frames defined below shall follow the rules of the reverse direction protocol.

A STA initiates fast link adaptation by transmitting a Link Measurement Request frame that is of subtype Action No Ack and that has the Dialog Token field set to 0. The PPDU containing the frame shall have the AGGREGATION parameter in the TXVECTOR set to AGGREGATED, shall not contain any other frame that requires immediate response, and shall have a duration (as determined by the PLME-TXTIME.confirm primitive defined in 6.7.6) that is greater than 5.27 μs.

NOTE—The PPDUs have the AGGREGATION parameter in the TXVECTOR set to AGGREGATED to allow padding of the PSDUs with MPDU delimiters of size 0, therefore meeting the transmission duration requirement.

A STA that supports fast link adaptation and that receives a Link Measurement Request frame of subtype Action No Ack with the Dialog Token field equal to 0 and contained in a PPDU with the AGGREGATION parameter in the RXVECTOR equal to AGGREGATED shall respond with a Link Measurement Report frame in no longer than BRPIFS from the reception of the Link Measurement Request frame. The TPC Report element, CMMG Link Margin element and other fields transmitted in the Link Measurement Report frame

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

shall reflect measurements on the PPDU that contained the last received Link Measurement Request frame from the initiating STA.

The STA responding with the Link Measurement Report frame shall keep the IFS not longer than a SIFS by transmitting PPDUs that do not contain frames requiring immediate response and that have a duration that is greater than 5.27 μs. All transmitted PPDUs should use the same MCS and the same transmit power.

The transmitted Link Measurement Report frame shall be of subtype Action No Ack, shall be sent using MCS 1, and shall be sent within a PPDU with the AGGREGATION parameter in the TXVECTOR set to AGGREGATED. In addition, the PPDU shall not contain any frame that requires immediate response and shall have a duration that is greater than 5.27 μs.

If at least one of the conditions above for the transmission of the Link Measurement Report frame is not met, the STA may follow the rules in 10.31.1 to respond to the received Link Measurement Request frame.

A STA that supports fast link adaptation and that receives a Link Measurement Report frame should respond with an unsolicited Link Measurement Report frame in no longer than BRPIFS from the reception of the Link Measurement Report frame. The TPC Report element, CMMG Link Margin element, and other fields transmitted in the unsolicited Link Measurement Report frame shall reflect measurements taken on one or more of the PPDUs received by the STA transmitting the unsolicited Link Measurement Report frame, starting with the received Link Measurement Report frame itself. If the unsolicited Link Measurement Report frame is transmitted longer than a SIFS from the reception of the Link Measurement Report frame, the STA transmitting the unsolicited Link Measurement Report frame shall keep the IFS not longer than a SIFS by transmitting one or more PPDUs before issuing the unsolicited Link Measurement Report frame.

10.44 DMG relay operation

10.44.1 General

The DMG relay procedures are specified in 11.34. This subclause specifies the supported types of DMG relay.

DMG relay operation is not supported by an IBSS STA. dot11RelayActivated is false in an IBSS STA.

A source REDS, a destination REDS and an RDS can establish two types of relay operation:

— Link switching (10.44.2): If the direct link between the source REDS and destination REDS is disrupted, the source REDS redirects the transmission of frames addressed to the destination REDS via the RDS. The RDS forwards frames received from the source REDS to the destination REDS and from the destination REDS to the source REDS. Direct communication between the source REDS and destination REDS might resume after the direct link between them is recovered.

— Link cooperation (10.44.3): In this case, the RDS is actively involved in the direct communication between the source REDS and the destination REDS. A frame transmission from the source REDS to the destination REDS is simultaneously repeated by the RDS, which might possibly increase the signal quality received at the destination REDS.

10.44.2 Link switching

10.44.2.1 General

A source REDS that has successfully completed an RLS procedure with a destination REDS for which the value of the Cooperation-Mode subfield within the negotiated Relay Transfer Parameter Set element is 0 may use the selected RDS between the source REDS and destination REDS for the purpose of link switching. This is described in this subclause.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

10.44.2.2 SP request and allocation

The source REDS uses the procedures described in 11.4 to request an SP allocation between itself and the destination REDS.

Upon receiving an ADDTS Request frame for which the source AID and the destination AID fields within the DMG TSPEC element are equal to a pair of a source REDS and a destination REDS, respectively, that have successfully completed the RLS procedure defined in 11.34.2.4, the AP or PCP schedules an SP with the source DMG STA as the source REDS and the destination DMG STA as the destination REDS.

An RDS shall check the value of the source AID and the destination AID fields of each SP allocation within an Extended Schedule element it receives in a DMG Beacon or Announce frame from the AP or PCP. If the value of the source AID and the destination AID fields of an SP allocation correspond to a source REDS and a destination REDS, respectively, that have successfully completed the RLS setup procedure (11.34.2), the RDS shall operate as an RDS during that SP allocation.

10.44.2.3 Usage of RDS

In link switching, an RDS operates either in FD-AF mode or in HD-DF mode. An RDS capable of FD-AF relaying shall be in one of two frame transmission modes:

— *Normal mode*: A pair of source REDS and destination REDS exchange frames via either the direct link or the relay link until this link is determined to become unavailable due to, for example, blockage or channel degradation.

— *Alternation mode*: A source REDS and a destination REDS exchange frames via two separate links, where the use of each link alternates at each link change interval. The link change interval specifies the time instants at which a source REDS is allowed to change the link used for a frame transmission to the destination REDS as specified in 9.4.2.147.

An RDS that supports only HD-DF shall operate in the Normal mode.

The frame transmission mode is indicated in the Relay Transfer Parameter Set element exchanged by the source REDS, destination REDS, and RDS during the RLS procedure. A source REDS or destination REDS may change the transmission mode used in a relay link following successful transmission of RLS Request and RLS Response frames as described in 11.34.2.4.

An RDS shall start to operate as RDS at the start of an SP for which the value of the source AID and destination AID fields for that SP are equal to the source REDS and destination REDS, respectively, for which the RDS has successfully completed the RLS procedure. The RDS can determine the SPs for which it operates as an RDS upon reception of an Extended Schedule element.

10.44.2.4 Relay frame exchange rules

10.44.2.4.1 General

Following the completion of the RLS procedure and SP allocation, each of the source REDS, destination REDS, and RDS have a direct link with one another.

The values of link change interval and data sensing time are indicated within the Relay Transfer Parameter Set transmitted by the source REDS to the destination REDS during the RLS procedure. Either the link change interval period or the first period begins at the start of an SP between the source REDS and the destination REDS, and any transmission by the source REDS, destination REDS, and RDS within a link change interval period shall use the same link that is used at the start of the link change interval period. A

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

new link change interval period starts immediately after another link change interval period, but shall not exceed the end of the SP.

In the normal mode, a source REDS shall use the direct link to initiate frame transmission to the destination REDS at the start of the first SP allocated between the source REDS and destination REDS for a particular TID. At the start of the following SP allocations for that same TID, the source REDS uses the last link in which a frame transmission to the destination REDS via this link was successful. In the alternation mode, the source DMG STA shall alternate the frame transmission to the destination REDS between direct frame transmission to the destination REDS and frame transmission through the RDS. The source REDS shall alternate the link used for a frame transmission at the start of each link change interval.

If a source REDS transmits a frame to the destination REDS via the direct link but does not receive an expected Ack frame or BlockAck frame from the destination REDS during a link change interval period, the source REDS should change the link used for frame transmission at the start of the following link change interval period and use the RDS to forward frames to the destination REDS.

If a source REDS transmits a frame to the destination REDS via the RDS but does not receive an expected Ack frame or BlockAck frame from the RDS during a link change interval period or a first period, the source REDS should change the link used for frame transmission at the start of the following link change interval period or the following first period and transmit frames directly to the destination REDS.

10.44.2.4.2 Additional frame exchange rules for FD-AF RDS

If the source REDS decides to change the link at the start of the following link change interval period and the Normal mode is used, the source REDS shall start its frame transmission after data sensing time from the start of the following link change interval period. If the Alternation mode is used, the source REDS alternates the link used for frame transmission at the start of each link change interval period, and the value of data sensing time is ignored.

In the Normal mode, if the destination REDS does not receive a frame from the source REDS within data sensing time after the start of a link change interval, the destination REDS shall immediately change the link to attempt to receive frames from the source REDS through the RDS. If the More Data subfield in the last frame received from the source REDS is equal to 0, then the destination REDS shall not switch to the link in the next link change interval period even if it does not receive a frame during the data sensing time. An example of frame transfer under Normal mode with FD-AF RDS is illustrated in Figure 10-136 (Example of Normal mode operation with FD-AF relay).

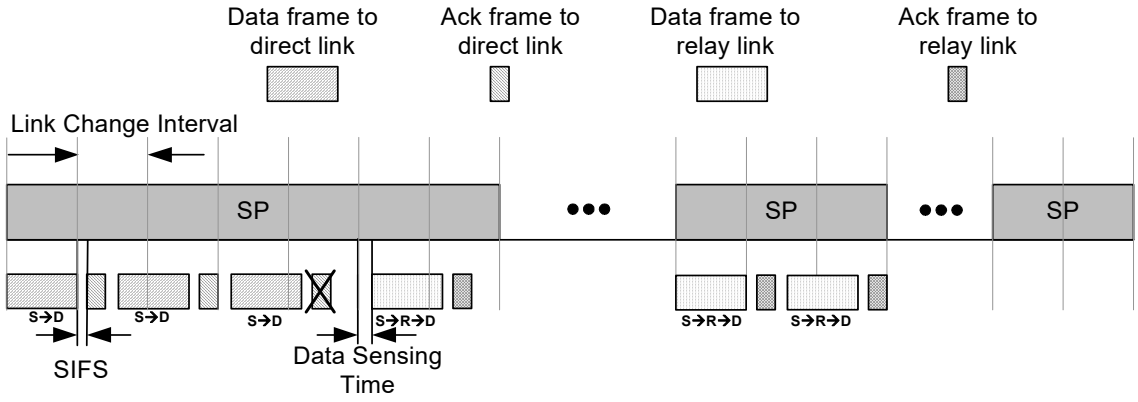

Figure 10-136—Example of Normal mode operation with FD-AF relay

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In the Alternation mode, if the destination REDS receives an out of order frame, the destination REDS shall remain at the current link. If the More Data subfield in the last frame received from the source REDS is equal to 0, then the destination REDS shall not switch links in the next link change interval period. If the source REDS uses either the direct or the relay link and decides to resume alternate frame transmission, the source REDS should transmit a frame to the other link data sensing time after the next link change interval to inform the destination REDS that operation on the other link has been resumed. Note that this is the only situation when data sensing time is used in the Alternation mode.

10.44.2.4.3 Additional frame exchange rules for HD-DF RDS

When the RDS is operating as a HD-DF RDS and the RDS is used in the frame exchange between the source REDS and the destination REDS, the frame exchange is performed in two periods, which are repeated for as long as the RDS is used. In the first period, the source REDS shall transmit a frame to the RDS and then the RDS responds after a SIFS if needed. In the second period, the RDS shall forward the frame received from the source REDS to the destination REDS, and then the destination REDS responds after a SIFS if needed. The duration of the first period and the second period are specified in the last Relay Transfer Parameter Set element transmitted from the source REDS.

The first period and second period are valid only when the source REDS and destination REDS exchange frames via the RDS. The link change interval is valid only when the source REDS and destination REDS exchange frames via the direct link. The first period begins at the end of the link change interval when a change to the relay link occurs. The link change interval begins at the end of the second period when a change to the direct link occurs.

The source REDS may transmit a Relay Ack Request frame to the RDS to determine whether all frames forwarded through the RDS were received by the destination REDS. Upon reception of a Relay Ack Request frame, the RDS shall respond with a Relay Ack Response frame with the Block Ack Starting Sequence Control field set to the same value as in the Relay Ack Request frame and the BlockAck Bitmap field set to indicate which frames have been received by the destination REDS.

If the source REDS decides to change to the relay link at the start of the following link change interval period, the source REDS shall start its frame transmission at the start of the following link change interval period. If the current link is the direct link and the destination REDS does not receive a frame from the source REDS within data sensing time after the start of each link change interval, the destination REDS shall change the link and consider the first period to begin at the start of the link change interval.

If a link change to the direct link occurs, the source REDS shall start to transmit a frame using the direct link at the end of the second period when the link change interval begins. The destination REDS shall switch to the direct link at each first period and listen to the medium toward the source REDS. If the destination REDS receives a frame from the source REDS, the destination REDS shall remain on the direct link and consider the link change interval to begin at the start of the first period. Otherwise, the destination REDS shall change the link at the start of the next second period and attempt to receive frames from the source REDS through the RDS. If the active link is the relay link and the More Data subfield in the last frame received from the RDS is equal to 0, then the destination REDS shall not switch to the direct link even if it does not receive any frame during the second period.

In order to use the block ack mechanism through the RDS, the source REDS shall perform the block ack setup procedure with the RDS using the same TID as was used for the direct communication between the source REDS and the destination REDS. Similarly, the RDS shall perform the block ack setup procedure with the destination REDS before transmitting data using the block ack mechanism. Upon reception of an ADDBA Request frame from the source REDS, the RDS shall send an ADDBA Request frame to the destination REDS with the same content for all corresponding fields as the ADDBA Request frame received from the source REDS, except for Buffer Size field, which contains the buffer size of the RDS. Following the reception of the ADDBA Response frame from the destination REDS, the RDS shall send an ADDBA

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Response frame to the source REDS. The ADDBA Response frame shall have the same content for all corresponding fields as the ADDBA Response frame received from the destination REDS, except for the Buffer Size field, which shall be set to the minimum between the buffer size of the RDS and the destination REDS.

An example of frame transfer with HD-DF RDS is illustrated in Figure 10-137 (Example of operation with HD-DF relay).

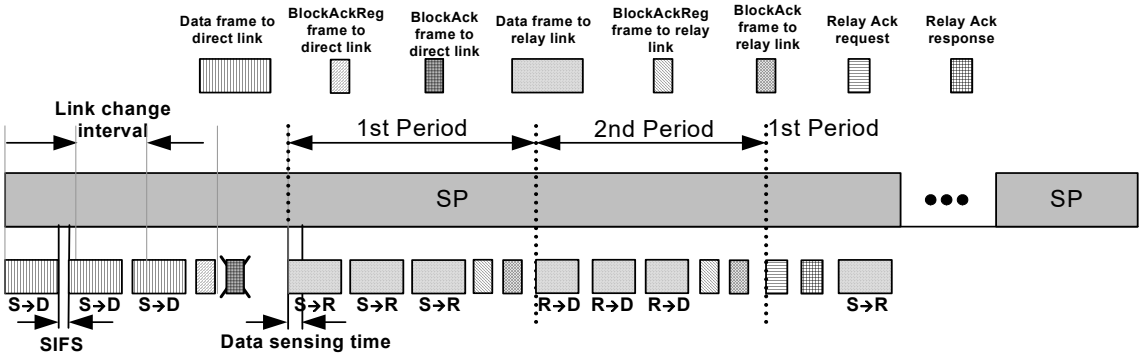

Figure 10-137—Example of operation with HD-DF relay

10.44.2.4.4 Operation of FD-AF RDS

In an SP allocated for relay operation, a FD-AF RDS operates in an amplify-and-forward manner. This means that for each frame detected at the RF in the receive state within an SP in which it operates as a FD-AF RDS, the RDS amplifies the received signal and simultaneously retransmits it via the RF in transmit state.

At the start of the SP where it operates as a FD-AF RDS, the RDS shall initiate an RF antenna module in the receive state directed toward the source REDS and another RF antenna module in transmit state directed toward the destination REDS.

For each frame received at the RDS during the SP, the RDS shall follow the same rules for frame exchange sequences as described in 10.38. This includes switching the state of each RF available to the RDS from receive to transmit, and vice versa, depending upon the frame type and its ack policy.

10.44.2.5 Link monitoring

After a link change, the source REDS might periodically monitor the quality of the previous link. To do that, the source REDS can use the link change mechanism described in 10.44.2.4. If the previous link is the relay link, the source REDS can acquire the channel status by using relay link measurement mechanism as described in 10.44.4. If the previous link is the direct link, the source REDS can acquire the channel status via the link adaptation mechanism defined in 10.41.9. If the channel quality of the previous link is better than the one on the current link, which is an implementation dependent decision, the source REDS may switch to the previous link.

10.44.3 Link cooperation

10.44.3.1 TPA procedure

A source REDS, a destination REDS, and an RDS use the common relay setup procedure defined in 11.34.2 to set up a link cooperation relay. In addition, to establish a link cooperation relay, the source REDS, destination REDS, and RDS shall perform the TPA procedure described in this subclause and shown in Figure 10-138 (TPA mechanism).

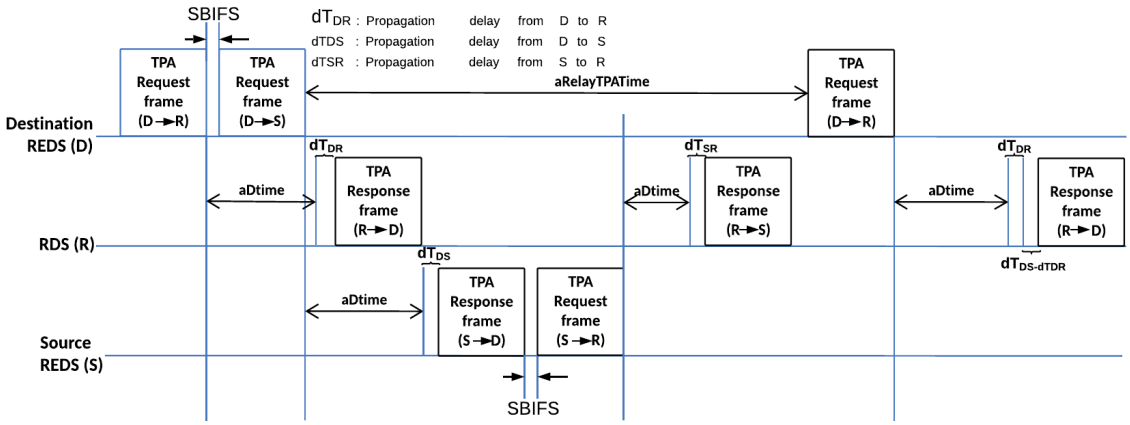

Figure 10-138—TPA mechanism

The TPA procedure is triggered by the destination REDS following the common relay setup procedure with the source REDS and RDS. First, the destination REDS uses the procedures described in 11.4 to request the allocation of an SP to perform TPA, wherein the source of the SP is the destination REDS and the destination of the SP is the source REDS. If the value of a source AID and the destination AID fields of an SP allocation correspond to a destination REDS and a source REDS, respectively, that have successfully completed the RLS setup procedure, a STA that performs as an RDS in that SP allocation shall operate during the allocation as a non-RDS-capable DMG STA.

Within the allocated SP, the destination REDS sends a TPA Request frame to the RDS and sets the Timing Offset field to 0 (see Figure 10-138 (TPA mechanism)). SBIFS following the end of the first TPA Request frame transmission, the destination REDS shall send the second TPA Request frame to the source REDS and set the Timing Offset field to 0. aDtime interval (11.37) following the reception of the first TPA Request frame, the RDS shall transmit a TPA Response frame back to the destination REDS. Upon receiving the TPA Response frame from the RDS, the destination REDS shall estimate the TPA value of the RDS and the time deviation (i.e., $2 \times dT_{DR}$) between the expected Dtime and the actual arrival time of the TPA Response frame. aDtime interval following the reception of the second TPA Request frame, the source REDS shall transmit a TPA Response frame back to the destination REDS. The destination REDS shall repeat the same procedure upon reception of the TPA Response frame received from the source REDS.

SBIFS following the end of the transmission of the TPA Response frame to the destination REDS, the source REDS shall send a TPA Request frame to the RDS and set the Timing Offset field to 0. aDtime interval following the reception of the TPA Request frame, the RDS shall transmit a TPA Response frame back to the source REDS. Upon reception of the TPA Response frame from the RDS, the source REDS shall estimate the TPA value of the RDS and the time deviation (i.e., $2 \times dT_{SR}$) between aDtime and the actual arrival time of the TPA Response frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

At aRelayTPATime (11.37) from the end of the last TPA Request frame transmitted by the destination REDS to the source REDS, the destination REDS shall send a TPA Request frame to the RDS and set the Timing Offset field to $dT_{DS} - dT_{DR}$. Upon reception of the TPA Request frame, the RDS shall transmit a TPA Response frame to the destination REDS at $aDtime + dT_{DR} + (dT_{DS} - dT_{DR})$ from the end of the TPA Request frame. Upon reception of the TPA Response frame, the destination REDS shall estimate the time deviation [i.e., $2 \times dT_{DR} + (dT_{DS} - dT_{DR})$] between aDtime and the actual arrival time of the TPA Response frame. If the destination REDS determines that the estimated deviation is equal to $2 \times dT_{DR} + (dT_{DS} - dT_{DR})$, then the destination REDS considers that the TPA procedure was successful. As the last step of the TPA procedure, the destination REDS shall send a TPA Report frame to the source REDS that includes the information regardless of whether the last TPA procedure succeeded.

If it is not successful, the TPA procedure is repeated until it is successful or upon the decision of the destination REDS to stop performing the TPA procedure. The TPA procedure includes the estimation of the sampling frequency offset (SFO), in order for the source REDS and RDS to adjust their SFOs.

10.44.3.2 Link cooperation data transmission procedure

10.44.3.2.1 General

A source REDS that has successfully completed an RLS procedure with a destination REDS for which the value of the Cooperation-Mode subfield within the negotiated Relay Transfer Parameter Set element is equal to 1 and has successfully completed the TPA procedure shall use the selected RDS between the source REDS and destination REDS for the purpose of link cooperation. This is described in this subclause.

10.44.3.2.2 Cooperative transmission SP request and allocation

If the source REDS receives a TPA Report frame that indicates the successful completion of the TPA procedure with the RDS and the destination REDS, the source REDS uses the procedure in 11.4 to request an SP allocation with the destination REDS. The source REDS might use the SP allocation for communication with the destination REDS with the assistance of the RDS.

10.44.3.2.3 Data transmission rules

As shown in the example of Figure 10-139 (Example of data transmission in SP with link cooperation relay), in the allocated SP the first time interval (T1) and the second time interval (T2) for a cooperative Data frame transfer are determined by the PPDU transmission time at each transmission from the source REDS to the destination REDS within the SP.

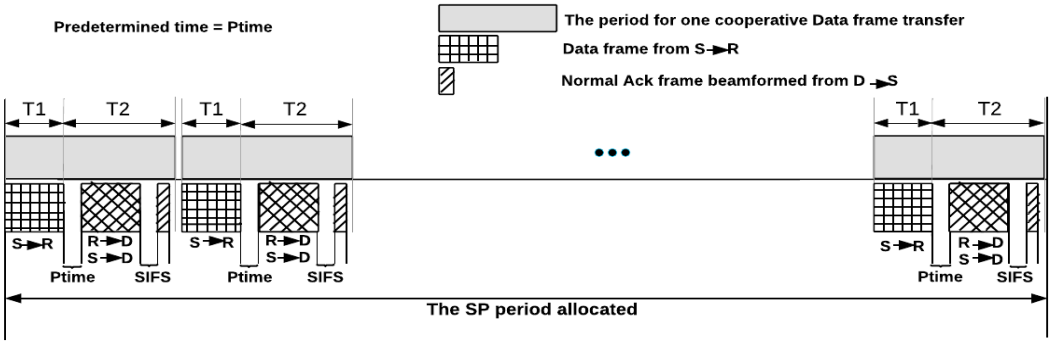

Figure 10-139—Example of data transmission in SP with link cooperation relay

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The data transmission rules are as follows. At the start of each time T1, the source REDS transmits a frame with its transmit antenna pattern directed toward the RDS and with the TA and the RA fields in the MAC header set to the MAC address of the source REDS and destination REDS, respectively. After $Ptime + dT_{SR}$ from the start of T2, the source REDS retransmits the same frame sent to the RDS during the previous time T1 but now with its transmit antenna pattern directed toward the destination REDS. Similarly, after $Ptime + (dT_{DS} - dT_{DR})$ from the start of T2, the RDS retransmits the same frame it received from the source REDS during the previous time T1. So that the destination REDS might take advantage of the improved received signal level from both of these transmissions, the destination REDS should set its receive antenna pattern during T2 such that it simultaneously covers the links toward both the source REDS and the RDS.

10.44.4 Relay link adaptation

When a relay link is used for communication between a source REDS and a destination REDS, the link qualities of the S-R link, the R-D link, and the S-D link might be required.

The source REDS, destination REDS, and RDS use the procedure described in 10.41.9 to request and report the link quality among themselves with the following exception. In the Link Measurement Report frame the RDS transmits to the source REDS, the RDS shall include two Link Margin elements in this order:

— The first Link Margin element shall report the link quality between the source REDS and the RDS.
— The second Link Margin element shall report the link quality between the RDS and the destination REDS.

Upon reception of a Link Measurement Report frame, the source REDS might take several actions including changing the MCS it uses for frame transmission to the RDS and destination REDS.

10.45 S1G BSS operation

10.45.1 Basic S1G BSS functionality

An S1G STA has dot11S1GOptionImplemented equal to true.

An S1G STA that is starting a BSS shall support receiving and transmitting at each of the <S1G-MCS, NSS> tuple values indicated by the Basic S1G-MCS and NSS Set field of the S1G Operation parameter of the MLME-START.request primitive and shall support receiving at each of the <S1G-MCS, NSS> tuple values indicated by the Supported S1G-MCS and NSS Set field of the S1G Capabilities parameter of the MLME-START.request primitive.

An S1G STA declares its channel width capability in the Supported Channel Width subfield of the S1G Capabilities element S1G Capabilities Information field as described in Table 9-351.

An S1G STA that is an S1G AP shall set the Channel Width subfield in the S1G Operation Information field of the S1G Operation element to indicate the BSS operating channel width as defined in Table 10-39, the location of 1 MHz primary channel as defined in Table 9-363 and whether MCS 10 is permitted but not recommended as defined in Table 9-363. Table 10-39 is the only combination allowed in an S1G BSS operation. The Channel Width field in the S1G Operation element not listed in Table 10-39 shall not be declared by an S1G STA that is an S1G AP.

An S1G STA shall determine the channelization based on the Channel Width, Primary Channel Number, and Channel Center Frequency subfields of the S1G Operation Information field (see 23.3.14).

An S1G STA that is a member of an S1G BSS with a 1 MHz, 2 MHz, 4 MHz, 8 MHz, or 16 MHz operating channel width and 1 MHz primary channel width shall not transmit a 1 MHz S1G PPDU that does not use the primary 1 MHz channel of the BSS, except for a 1 MHz S1G PPDU transmission on an off-channel

Copyright © 2025 IEEE. All rights reserved.

Table 10-39—S1G BSS operating channel width

S1G Operation element Primary Channel Width subfield	S1G Operation element BSS Channel Width subfield	BSS primary channel width (MHz)	BSS operating channel width (MHz)
0	1	2	2
0	3	2	4
0	7	2	8
0	15	2	16
1	0	1	1
1	1	1	2
1	3	1	4
1	7	1	8
1	15	1	16

TDLS direct link as constrained by 11.23.6.4.2 or a 1 MHz S1G PPDU transmission by an SST STA as constrained by 10.51.

An S1G STA that is a member of an S1G BSS with a 2 MHz, 4 MHz, 8 MHz, or 16 MHz operating channel width and 2 MHz primary channel width shall not transmit a 1 MHz S1G PPDU in a 1 MHz channel that is not the 1 MHz channel indicated by B5 of the Channel Bandwidth subfield in the S1G Operation element as defined in Table 9-363, except for a 1 MHz S1G PPDU transmission on an off-channel TDLS direct link or a 1 MHz S1G PPDU transmission by an SST STA as constrained by 10.51.

An S1G STA that is a member of an S1G BSS with a 2 MHz, 4 MHz, 8 MHz, or 16 MHz operating channel width shall not transmit a 2 MHz S1G PPDU that does not use the primary 2 MHz channel of the BSS, except for a 2 MHz S1G PPDU transmission either on an off-channel TDLS direct link or a 2 MHz S1G PPDU transmission by an SST STA as constrained by 10.51.

An S1G STA that is a member of an S1G BSS with a 4 MHz, 8 MHz, or 16 MHz operating channel width shall not transmit a 4 MHz S1G PPDU that does not use the primary 4 MHz channel of the BSS, except for a 4 MHz S1G PPDU transmission either on an off-channel TDLS direct link or by an SST STA as constrained by 10.51.

An S1G STA that is a member of an S1G BSS with an 8 MHz or 16 MHz operating channel width shall not transmit an 8 MHz S1G PPDU that does not use the primary 8 MHz channel of the BSS, except for an 8 MHz S1G PPDU transmission either on an off-channel TDLS direct link or by an SST STA as constrained by 10.51.

An S1G STA that is a member of an S1G BSS with a 16 MHz operating channel width shall not transmit a 16 MHz S1G PPDU that does not use the primary 8 MHz channel and the secondary 8 MHz channel of the BSS, except for a 16 MHz S1G PPDU transmission on an off-channel TDLS direct link.

An S1G STA shall not transmit to a second S1G STA using a bandwidth that is not indicated as supported in the Supported Channel Width subfield in the S1G Capabilities element received from that S1G STA.

An S1G STA shall set the BSS BW field in the Frame Control field of the S1G Beacon frame in line with the values defined in Table 10-39 that are included in the S1G Operation element transmitted by the STA.

10.45.2 System information update procedure

The S1G AP shall increase the value (modulo 256) of the Change Sequence field in the next transmitted S1G Beacon frame(s) when a critical update occurs to any of the elements inside the S1G Beacon frame. The following events shall classify as a critical update:

a) Inclusion of an Extended Channel Switch Announcement
b) Modification of the EDCA parameters
c) Modification of the S1G Operation element

An S1G AP can classify other changes in the S1G Beacon frame as critical updates and among these updates can be included those that are described in 11.2.3.14.

The S1G STA shall either be awake to receive the next S1G Beacon frame that is transmitted at a TBTT or shall queue for transmission a Probe Request frame when it receives a Change Sequence field that contains a value that is different from the previously received Change Sequence field. When an S1G STA transmits a Probe Request frame to obtain the updated system information, it may include the Change Sequence element in the Probe Request frame to request a compressed Probe Response frame.

When an S1G AP receives a Probe Request frame that contains a Change Sequence element from an S1G STA associated with the S1G AP, it compares the value of the received Change Sequence field with the value of its current Change Sequence field. If the value of the received Change Sequence field is not equal to the value of the current Change Sequence field, the S1G AP should send a compressed Probe Response frame, which is a Probe Response frame that includes the Change Sequence element and only the elements that need be updated by the STA. Otherwise, the AP shall send a Probe Response frame as defined in 11.1.4.3.4.

10.45.3 S1G BSS channel selection methods

Before an S1G STA starts an S1G BSS, the STA shall perform a minimum of dot11S1GOBSSScanCount OBSS scan operations to search for existing BSSs (see 10.45.5).

If an S1G AP starts an S1G BSS with a 2 MHz primary channel width that occupies some or all channels of any existing BSSs, the S1G AP may select a 2 MHz primary channel of the new S1G BSS that is identical to the 2 MHz primary channel of any one of the existing BSSs.

If an S1G AP selects a 2 MHz primary channel for a new S1G BSS with a 4 MHz, 8 MHz, or 16 MHz operating channel width from among the channels on which no beacons are detected during the OBSS scans, then the selected 2 MHz primary channel meets the following conditions:

— It shall not be identical to the secondary 2 MHz channel of any existing BSSs with a 4 MHz, 8 MHz, or 16 MHz operating channel width.
— It should not overlap with the secondary 4 MHz channel of any existing BSSs with a 16 MHz operating channel width.

An S1G STA that is an S1G AP should not start an S1G BSS with a 2 MHz operating channel width on a channel that is the secondary 2 MHz channel of any existing BSSs with a 4 MHz, 8 MHz, or 16 MHz operating channel width, or is overlapped with the secondary 4 MHz channel of any existing BSSs with a 16 MHz operating channel width.

NOTE—An S1G AP operating an S1G BSS with a 4 MHz, 8 MHz, or 16 MHz operating channel width, on detecting an OBSS whose primary channel is the S1G AP's secondary 2 MHz channel, might switch to 2 MHz BSS operation and/or move to a different channel.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If an S1G AP starts an S1G BSS with a 1 MHz primary channel width that occupies some or all channels of any existing BSSs, the S1G AP may select a 1 MHz primary channel of the new S1G BSS that is identical to the 1 MHz primary channel of any one of the existing BSSs.

If an S1G AP selects a 1 MHz primary channel for a new S1G BSS with a 2 MHz, 4 MHz, 8 MHz, or 16 MHz operating channel width from among the channels on which no beacons are detected during the OBSS scans, then the selected 1 MHz primary channel meets the following conditions:

— It shall not be identical to the secondary 1 MHz channel of any existing BSSs with a 2 MHz, 4 MHz, 8 MHz, or 16 MHz operating channel width.

An S1G STA that is an S1G AP should not start an S1G BSS with a 1 MHz operating channel width on a channel that is the secondary 1 MHz channel of any existing BSSs with a 2 MHz, 4 MHz, 8 MHz, or 16 MHz operating channel width.

When establishing a BSS with a 2 MHz, 4 MHz, 8 MHz, or 16 MHz operating channel width, the S1G AP determines and announces the location of 1 MHz primary channel located at either upper or lower side of the 2 MHz primary channel.

10.45.4 S1G BSS channel switching methods

An S1G AP announces a switch of operating channel by using the Extended Channel Switch Announcement element, Extended Channel Switch Announcement frame or both, following the procedure described in 11.9.

An S1G AP may also announce a switch of operating channel width, a new Country String field (possibly including a new Operating Class table number), new operating classes or new TPC parameters for the BSS that come into effect at the same time as the switch of operating channel.

The New Channel Number field in the Extended Channel Switch Announcement element or Extended Channel Switch Announcement frame identifies the primary channel after the switch. The value of the New Channel Number field is set to the value that dot11CurrentPrimaryChannel (see 23.3.14 (Channelization)) will have after the switch.

10.45.5 Scanning requirements for S1G STA

An OBSS scan operation is a passive or active scan of a set of channels that are potentially affected by S1G BSS operation (see 11.1.4.1 (General)). Each channel in the set may be scanned more than once during a single OBSS scan operation. OBSS scans are performed by S1G STAs that start an S1G BSS.

During an individual scan within an OBSS scan operation, the minimum per-channel scan duration is dot11OBSSScanPassiveDwell TUs (for a passive scan) or dot11OBSSScanActiveDwell TUs (for an active scan). During an OBSS scan operation, each channel in the set is scanned at least once per dot11BSSWidthTriggerScanInterval seconds, and the minimum total scan time (i.e., the sum of the scan durations) per channel within a single OBSS scan operation is dot11OBSSScanPassiveTotalPerChannel TUs (for a passive scan) or dot11OBSSScanActiveTotalPerChannel TUs (for an active scan).

NOTE—The values provided in the previous paragraph are minimum requirements. For some combinations of parameter values the minimum might be exceeded for some parameters in order to meet the minimum value constraints of other parameters.

10.45.6 NAV and RID assertion in an S1G BSS

An S1G STA shall update its NAV as described in 10.3.2.4 using the Duration/ID field value in any frame that does not have an RA matching the STA's MAC address or the Duration field value in NDP CMAC

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

PPDUs of which it is not the recipient STA and that was received in a 1 MHz PPDU in the primary 1 MHz channel or received in a 2 MHz PPDU in the primary 2 MHz channel or received in a 4 MHz PPDU in the primary 4 MHz channel or received in an 8 MHz PPDU in the primary 8 MHz channel or received in a 16 MHz PPDU.

An S1G STA shall update its RID as described in 10.3.2.5 using the RXVECTOR parameters in any frame that was received in a 1 MHz PPDU in the primary 1 MHz channel or received in a 2 MHz PPDU in the primary 2 MHz channel or received in a 4 MHz PPDU in the primary 4 MHz channel or received in an 8 MHz PPDU in the primary 8 MHz channel or received in a 16 MHz PPDU.

NOTE—The PHY layer might filter out a PPDU as described in 23.3.20. If so, frames in the PPDU are not received by the MAC and have no effect on the NAV.

10.45.7 BSS Basic S1G-MCS and NSS set operation

The BSS basic S1G-MCS and NSS set is the set of <S1G-MCS, NSS> tuples that are supported by all S1G STAs that are members of an S1G BSS, where the S1G-MCS values refer to those obtained from the Max S1G-MCS For n SS subfields of the S1G Operation element as defined in 9.4.2.211. It is established by the STA that starts the S1G BSS, indicated by the Basic S1G-MCS and NSS Set field of the S1G Operation element in the MLME-START.request primitive. Other S1G STAs determine the BSS basic S1G-MCS and NSS set from the Basic S1G-MCS and NSS Set field of the S1G Operation element in the BSSDescription derived through the scan mechanism (see 11.1.4.1).

An S1G STA shall not attempt to join (MLME-JOIN.request primitive) a BSS unless it supports (i.e., is able to both transmit and receive using) all the <S1G-MCS, NSS> tuples in the BSS basic S1G-MCS and NSS set.

An S1G STA shall not attempt to (re)associate (MLME-ASSOCIATE.request primitive and MLME-REASSOCIATE.request primitive) with an S1G AP unless the S1G STA supports (i.e., is able to both transmit and receive using) all the <S1G-MCS, NSS> tuples in the Basic S1G-MCS and NSS Set field in the S1G Operation element transmitted by the S1G AP.

The BSS basic S1G-MCS and NSS set is defined by Max S1G-MCS, which indicate the mandatory values and Min S1G-MCS, which indicate the recommended values as defined in 9.4.2.211 and 10.6.14.

An S1G AP that indicates support for sensor STAs does not indicate minimum MCS restrictions.

10.45.8 S1G coexistence with non-IEEE-802.11 systems

This subclause describes the features available in this standard to improve coexistence with other systems operating in bands below 1 GHz, including IEEE Std 802.15.4 and IEEE Std 802.15.4g.

An S1G STA uses energy detection (ED) based CCA with a threshold of –75 dBm per MHz to improve coexistence with other S1G systems. If an S1G STA detects energy above that threshold on its channel, as described in 23.3.18.5, then the following mechanisms might be used to mitigate interference:

— Change of operating channel (11.9)
— Sectorized beamforming (10.52)
— Change the schedule of RAW(s) (10.23.5), TWT SP(s) (10.46), or SST operating channels (10.51)
— Defer transmission for a particular interval (10.60)

10.46 Target wake time (TWT)

10.46.1 TWT overview

Target wake times (TWTs) allow STAs to manage activity in the BSS by scheduling STAs to operate at different times in order to minimize contention and to reduce the required amount of time that a STA utilizing a power management mode needs to be awake. TWTs can be individual TWTs, which are described in 10.46 and 26.8.2, or broadcast TWTs, which are described in 26.8.3.

When performing the TWT operations described in 10.46.1 to 10.46.8, if management frame protection is negotiated and both STAs set the Protected TWT Operations Support field in the RSNXE that they transmit to 1, the STAs shall

— Use individually addressed Protected TWT Setup, Protected TWT Teardown, and Protected TWT Information frames instead of TWT Setup, TWT Teardown, and TWT Information frames, respectively,

— Not transmit BAT, STACK, or TACK frames, and

— Discard any individually addressed TWT Setup, TWT Teardown, TWT Information, BAT, STACK, or TACK frame received from the peer STA, with which management frame protection is negotiated.

STAs that exchange individually addressed Protected TWT Setup, Protected TWT Teardown, or Protected TWT Information frame shall follow the rules defined in 12.6.17.

When management frame protection is not negotiated or the Protected TWT Operations Support field in the RSNXE transmitted by either STA is 0, the STAs shall not use any of the Protected TWT Setup frame, the Protected TWT Teardown frame, and the Protected TWT Information frame.

STAs that request a TWT agreement are called TWT requesting STAs and the STAs that respond to their requests are TWT responding STAs. A TWT requesting STA is assigned specific times to wake and exchange frames with the TWT responding STA. A TWT requesting STA communicates wake scheduling information to its TWT responding STA and the TWT responding STA devises a schedule and delivers TWT values to the TWT requesting STA when a TWT agreement has been established between them. When explicit TWT is employed, a TWT requesting STA wakes and performs a frame exchange and receives the information for the next target wake time for any of the explicit TWT agreements of which the STA is a member, in a response from the TWT responding STA as described in 10.46.3. When implicit TWT is used, the TWT requesting STA calculates the Next TWT by adding a fixed value to the current TWT value as described in 10.46.4. STAs need not be made aware of the TWT values of other STAs. A TWT requesting STA and a TWT responding STA shall set the Negotiation Type subfield to 0 in the TWT element of transmitted frames containing the TWT element, except when the STAs are HE STAs. Additional TWT setup exchanges between HE STAs for individual TWT operation are defined in 26.8.

The maximum number of active TWT agreements between any pair of STAs cannot exceed 8, since the TWT Flow Identifier field of the TWT element comprises 3 bits. TWT responding STAs may protect TWT times with protection mechanisms including, but not limited to NAV-setting frame exchange sequences. TWT responding STAs that are APs may additionally protect TWT times using RAW scheduling. TWT requesting STAs may wake at times other than TWT. An AP that is a TWT requesting STA shall not be in doze state for a duration that exceeds the value of the dot11MaxAwayDuration during a beacon interval or short beacon interval, as defined in 11.2.3.17.

An S1G STA with dot11TWTOptionActivated equal to true and that operates in the role of TWT requesting STA shall set the TWT Requester Support subfield to 1 in all S1G Capabilities elements that it transmits. An S1G STA with dot11TWTOptionActivated equal to true and that operates in the role of TWT responding STA shall set the TWT Responder Support subfield to 1 in all S1G Capabilities elements that it transmits.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA that is not an S1G STA and is not an HE STA and with dot11TWTOptionActivated equal to true and that operates in the role of TWT requesting STA shall set the TWT Requester Support subfield to 1 in all Extended Capabilities elements that it transmits. A STA that is not an S1G STA and is not an HE STA and with dot11TWTOptionActivated equal to true and that operates in the role of TWT responding STA shall set the TWT Responder Support subfield to 1 in all Extended Capabilities elements that it transmits.

If the TWT Responder Support subfield of the S1G Capabilities element, HE Capabilities element, or Extended Capabilities element received from its associated AP is equal to 1, a non-AP STA with dot11TWTOptionActivated equal to true may transmit a TWT element to the AP with a value of Request TWT, Suggest TWT, or Demand TWT in the TWT Setup Command field and with the TWT Request field equal to 1.

An AP with dot11TWTOptionActivated equal to true shall transmit a TWT element to a STA that is associated to the AP and from which it received a frame containing a TWT element that contained a value of Request TWT, Suggest TWT or Demand TWT in the TWT Setup Command field and with the TWT Request field equal to 1, except when the received frame is a (Re)Association Request frame sent by an HE STA, in which case the AP should transmit a TWT element to the STA. The transmitted TWT element shall be included in the frame that is the appropriate response frame to the received frame. The AP shall include a value of Accept TWT, Alternate TWT, Dictate TWT or Reject TWT in the TWT Setup Command field of the response and shall set the TWT Request field to 0. If the AP response's TWT Setup Command field includes anything other than Accept TWT or Reject TWT, the STA should send a new request for a TWT value by sending another frame that contains a TWT element, modifying the parameters of the request to indicate, for example, an acceptance of a proposed alternate TWT or dictated TWT value. If the STA receives a TWT response to a TWT request with the TWT Setup Command field value of Accept TWT, then the STA has successfully completed a TWT setup with that STA for the TWT Flow Identifier indicated in the TWT response and the STA becomes a TWT requesting STA and the STA may enter the doze state until the TSF matches the next TWT value of the STA, provided that the STA has indicated that it is in a power save mode and no other condition requires the STA to remain awake. The AP becomes a TWT responding STA of the TWT requesting STA.

NOTE 1—A TWT responding STA might choose a TWT Flow Identifier for the TWT response that is different from the TWT Flow Identifier of a received TWT request.

NOTE 2—If the frame that contains the TWT element is a (Re)Association Request frame, and the (Re)Association Response frame that is sent in response does not contain a TWT element then the non-AP STA can transmit another TWT request to the associated AP after (re)association.

NOTE 3—A TWT requesting STA might renegotiate the TWT parameters of an existing TWT agreement by sending to the TWT responding STA a TWT request with a Flow Identifier that corresponds to that TWT agreement. The TWT response sent by the TWT responding STA containing the TWT Setup Command field of Accept TWT indicateswhether the newly requested TWT parameters are accepted or whether the previously negotiated TWT parameters are still in place.

The result of an exchange of TWT Setup frames between a TWT requesting STA and a TWT responding STA is defined in Table 10-40.

- "Request TWT" indicates that the requesting STA does not provide a set of TWT parameters for a TWT agreement, leaving the choice of parameters to the responding STA.
- "Suggest TWT" indicates that the requesting STA offers a set of preferred TWT parameters for a TWT agreement but might accept alternative TWT parameters that the responding STA indicates.
- "Demand TWT" indicates that the requesting STA currently accepts only the indicated TWT parameters for a TWT agreement.

For transmissions by a responding STA,

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— "Accept TWT" indicates that the responding STA has initiated a TWT agreement with the given parameters.
— "Alternate TWT" indicates a counter-offer of TWT parameters (although alternative TWT parameters might be accepted as well) without the creation of a TWT agreement.
— "Dictate TWT" indicates that no TWT agreement is created, but one is likely to be accepted only if the requesting STA transmits a new TWT setup request with the indicated TWT parameters (i.e., no other TWT parameters will be accepted).

For transmissions by a responding STA as part of a negotiation for a new TWT agreement, "Reject TWT" indicates that the negotiation has ended in failure to create a new TWT agreement.

Table 10-40—TWT setup exchange command interpretation

TWT Setup Command field in an initiating frame	TWT Setup Command field value in a response frame	TWT condition after the completion of the exchange
Request TWT, Suggest TWT, or Demand TWT	No frame transmitted	No new individual TWT agreement exists with the TWT flow identifier corresponding to the TWT flow identifier in the initiating frame. No new individual TWT agreement exists.
Demand TWT	Accept TWT	An individual TWT agreement exists that uses the TWT parameters identified in the initiating frame. The TWT parameters in the response frame match the TWT parameters of the initiating frame.
Suggest TWT or Request TWT	Accept TWT	An individual TWT agreement exists and uses the TWT parameters identified in the response frame.
Demand TWT or Suggest TWT	Alternate TWT	No individual TWT agreement exists with the associated TWT flow identifier. The responder is offering an alternative set of parameters to those indicated in the initiating frame. The requesting STA can send a new request with any set of TWT parameters, and the responder might create an individual TWT agreement using those parameters.
Demand TWT or Suggest TWT	Dictate TWT	No individual TWT agreement exists with the associated TWT flow identifier. The responder STA offers an alternative set of parameters to those indicated in the initiating frame. The responder STA indicates that it is not willing to accept any other TWT parameters from the requesting STA at this time. The requesting STA can send a new request, but will receive an Accept TWT only if it uses the dictated TWT parameters.
Request TWT, Suggest TWT, or Demand TWT	Reject TWT	No individual TWT agreement exists with the associated TWT flow identifier. The responding STA will not create any new individual TWT agreement with the requester at this time.
NOTE 1—Negotiation Type subfield of the TWT element contained in these frames is equal to 0. NOTE 2—The initiating frame is a TWT request, and the response frame is a TWT response.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The receipt of a TWT command value of Suggest TWT implies that the STA sending the command will consider accepting a proposed TWT that differs from the value found in the TWT field of the element. The receipt of a TWT command value of Demand TWT implies that the STA sending the command will not consider accepting a proposed TWT that differs from the value found in the TWT field of the element. The receipt of a TWT command value of Alternate TWT implies that the STA sending the command will consider accepting a proposed TWT that differs from the value found in the TWT field of the element. The receipt of a TWT command value of Dictate TWT implies that the STA sending the command will not consider accepting a proposed TWT that differs from the value found in the TWT field of the element.

The MAC addresses of the TWT requesting STA and the TWT responding STA and the TWT Flow Identifier indicated in the TWT Response of a successful TWT setup between those two STAs uniquely identifies a TWT agreement. A MAC variable AdjustedMinimumTWTWakeDuration is defined for each TWT of each TWT agreement and has a value equal to Nominal Minimum TWT Wake Duration minus the elapsed time from the scheduled start of the TWT SP to the actual start of the SP, where the scheduled and actual start times of the TWT SP are determined after any necessary TSF adjustment. Because the value of the AdjustedMinimumTWTWakeDuration depends on the actual TWT SP start time, it is computed for each TWT SP once the TWT SP begins.

The TWT Wake Interval of a TWT agreement is the value calculated as shown in 9.4.2.198 from the TWT Wake Interval Mantissa and TWT Wake Interval Exponent of the TWT response that successfully completed the TWT agreement.

An AP may transmit a TWT element in an individually addressed TWT Setup frame with a value of Request TWT, Suggest TWT or Demand TWT in the TWT Command field and with the TWT Request field equal to 1 to an associated non-AP STA if the TWT Responder Support subfield in the S1G Capabilities element received from the STA is equal to 1. An AP may transmit TWT Setup frames to more than one of its associated non-AP STAs.

A non-AP STA with dot11TWTOptionActivated equal to true shall transmit a frame containing a TWT element to the AP with which it is associated and from which it received an individually addressed frame containing a TWT element that contained a value of Request TWT, Suggest TWT or Demand TWT in the TWT Command field and with the TWT Request field equal to 1. The transmitted TWT element shall be included in the frame that is the appropriate response frame to the received frame. The non-AP STA shall include a value of Accept TWT, Alternate TWT, Dictate TWT or Reject TWT in the TWT Command field of the response and shall set the TWT Request field to 0. If the non-AP STA response's TWT Command field includes anything other than Accept TWT or Reject TWT, the AP should send a new request for a TWT value by sending another frame that contains a TWT element, modifying the parameters of the request to indicate, for example an acceptance of a proposed alternate TWT or dictated TWT value. If the AP receives a TWT response to a TWT request with the TWT Command value of Accept TWT from an associated non-AP STA, then the AP has successfully completed a TWT setup with that STA for the TWT Flow Identifier indicated in the TWT response and the AP becomes a TWT requesting STA with respect to that STA.

A non-AP STA shall not transmit a frame containing a TWT element as a response to a group addressed frame with the TWT Request field equal to 1 that is transmitted by its associated AP.

If the NDP Paging field was not present in the TWT response corresponding to a TWT agreement, the TWT requesting STA shall be in the awake state following each TWT start time associated with each TWT agreement for the AdjustedMinimumTWTWakeDuration associated with that TWT agreement even if no PS-Poll frame, NDP PS-Poll frame, or U-APSD trigger frame has been transmitted by the STA or until it has received an EOSP field equal to 1 from the TWT responding STA, whichever occurs first. If the NDP Paging field was present in the TWT response, the TWT requesting STA shall follow the operational rules defined in 10.46.6.

If the Implicit bit is equal to 1 in the TWT response for a TWT agreement, the TWT associated with that TWT agreement is an implicit TWT and the TWT SP associated with that TWT is an implicit TWT SP. A TWT SP that is not an implicit TWT is an explicit TWT SP.

A TWT requesting STA that is a non-AP STA should transmit frames only within TWT SPs.

A TWT requesting STA that transmits a frame during a TWT SP is not granted any special medium access privileges, nor is there any guarantee that the TWT responding STA assigned the TWT SP to only one TWT requesting STA.

A single pair of STAs can create multiple TWT agreements. Each unique TWT agreement is identified by a TWT Flow Identifier and the MAC addresses of the TWT requesting STA and TWT responding STA. There are no explicit restrictions on the class of traffic (i.e., EDCA Access Category) that can be transmitted within any specific TWT SP when multiple TWT agreements have been set up by a single TWT requesting STA.

NOTE 4—The maximum number of TWTs for a single pair of STAs is 8.

A TWT requesting STA that is a non-AP STA may wake to receive Beacons that are transmitted outside of a TWT SP. A TWT requesting STA that is an AP generates S1G Beacon frames as described in 11.1.3 and operates in power save mode as described in 11.2.3.17.

A TWT responding STA should include a Pentapartial Timestamp field or a Tetrapartial Timestamp field or a Timestamp field in at least one frame transmitted to a TWT requesting STA during a TWT SP for that STA.

NOTE 5—When dot11TWTOptionActivated is true, a TWT responding STA might use the TWT Wake Interval in determining the lifetime of frames that it buffers for an TWT requesting STA.

The Flow Type field in the TWT response that successfully set up a TWT agreement indicates the type of interaction between the TWT requesting STA and the TWT responding STA within each TWT SP for that TWT agreement. Flow Type field equal to 0 indicates an announced TWT. The TWT responding STA of an announced TWT agreement shall not transmit a frame to the TWT requesting STA within a TWT SP until it has received a PS-Poll frame or APSD trigger frame (see 11.2.3.5) from the TWT requesting STA. Flow Type field equal to 1 indicates an unannounced TWT. The TWT responding STA of an unannounced TWT agreement may transmit a frame to the TWT requesting STA within a TWT SP before it has received a frame from the TWT requesting STA.

NOTE 6—A TWT requesting STA that is an AP does not send PS-Poll frames, but it can send APSD trigger frames.

A TWT requesting STA that is negotiating SST operation indicates which single channel it desires to use as a temporary primary channel during a TWT SP by setting a single bit to 1 within the TWT Channel field of the TWT element, according to the mapping described for that field. A TWT responding STA that is negotiating SST operation indicates which single channel the TWT requesting STA is permitted to use as a temporary primary channel during a TWT SP by setting a single bit to 1 within the TWT Channel field of the TWT element, according to the mapping described for that field. In an S1G BSS, during a TWT SP that was negotiated as part of SST operation, access to a channel that is not the primary channel of the BSS shall be performed according to the procedure described in 10.51.

In an HE BSS, during a trigger-enabled TWT SP, access to a channel that is not the primary channel of the BSS shall be performed according to the procedure described in 26.8.7.

If a STA has received a TWT Constraint Parameters element from another STA, it should not initiate a new TWT agreement or join a broadcast TWT schedule with that STA if the total number of TWT sessions/

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

schedules between the two STAs would exceed the value of the Max TWT Sessions field in the TWT Constraint Parameters element.

If a STA has received a TWT Constraint Parameters element from another STA and includes the Target Wake Time field in a TWT element transmitted to initiate a new TWT agreement with that STA, then it should set the Target Wake Time field to an integer multiple of $n + 1$ TUs [i.e., (Target Wake Time) mod $(n + 1) = 0$] where n is the value from the Starting Target Wake Time Alignment field of the most recent TWT Constraint Parameters element received from that STA.

10.46.2 TWT acknowledgment procedure

STAs need to be able to predict the duration of response transmissions for Duration field calculations and in addition, TWT requesting STAs might need TWT start times delivered in response frames. This subclause contains rules for TWT acknowledgments that allow both objectives to be satisfied at once by requiring specific responses to be transmitted in specific circumstances and by specifying the use of frames that provide both acknowledgment and next TWT information.

A TWT responding STA shall transmit a STACK frame in response to a frame received from a TWT requesting STA that has the value NORMAL_RESPONSE in the RXVECTOR parameter RESPONSE_INDICATION and that is not an A-MPDU and not an S-MPDU. A TWT responding STA shall transmit a TACK frame in response to a frame received from a TWT requesting STA that has the value NORMAL_RESPONSE in the RXVECTOR parameter RESPONSE_INDICATION and that is an S-MPDU unless the S-MPDU contains a BlockAckReq frame, in which case the response frame is a BAT frame. A TWT responding STA shall transmit a BAT frame in response to a frame received from a TWT requesting STA that has the value NORMAL_RESPONSE in the RXVECTOR parameter RESPONSE_INDICATION and that is an A-MPDU.

A TWT requesting STA with the transmitted TWT Responder Support subfield in the S1G Capabilities element equal to 1 shall transmit a STACK frame in response to a frame received from a TWT responding STA that has the value NORMAL_RESPONSE in the RXVECTOR parameter RESPONSE_INDICATION and that is not an A-MPDU and not an S-MPDU. A TWT requesting STA with the transmitted TWT Responder Support subfield in the S1G Capabilities element equal to 1 shall transmit a TACK frame in response to a frame received from a TWT responding STA that has the value NORMAL_RESPONSE in the RXVECTOR parameter RESPONSE_INDICATION and that is an S-MPDU unless the S-MPDU contains a BlockAckReq frame, in which case the response frame is a BAT frame. A TWT requesting STA with the transmitted TWT Responder Support subfield in the S1G Capabilities element equal to 1 shall transmit a BAT frame in response to a frame received from a TWT responding STA that has the value NORMAL_RESPONSE in the RXVECTOR parameter RESPONSE_INDICATION and that is an A-MPDU.

A TWT requesting STA that transmits a frame containing a Pentapartial Timestamp field shall set the field to all 0s. A TWT requesting STA that transmits a frame containing a Tetrapartial Timestamp field shall set the field to all 0s. A TWT requesting STA that transmits a frame containing a Next TWT Info field shall set the field to all 0s. A TWT requesting STA that transmits a frame containing a Change Sequence field shall set the field to all 0s.

A TWT requesting STA with the transmitted TWT Responder Support subfield in the S1G Capabilities element equal to 0 that receives a frame that requires an immediate response shall transmit an appropriate response is determined in 10.3.2.17.

If the intended recipient of a STACK or BAT frame is an AP, then the A1 field of the frame shall be set to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If a TWT responding STA or a TWT requesting STA receives a frame within a TWT SP that has a value other than NORMAL_RESPONSE in the RXVECTOR parameter RESPONSE_INDICATION, the appropriate response is as determined in 10.3.2.17.

10.46.3 Explicit TWT operation

Each TWT SP start value for an explicit TWT is transmitted by the TWT responding STA to the TWT requesting STA in the Next TWT Info/Suspend Duration field of a frame that can contain the field as described in this subclause. The TWT responding STA for an explicit TWT may provide TWT SP start times that are related to one another in a periodic or aperiodic manner.

During an explicit TWT SP, if a TWT responding STA receives a frame from a TWT requesting STA that permits a BAT frame, TACK frame or STACK frame to be sent in response, then the TWT responding STA shall respond with a frame that includes a Next TWT Info/Suspend Duration field either if it is required to do so according to 10.46.2, or if it has not already transmitted a nonzero Next TWT Info/Suspend Duration field to the STA within this TWT SP. If the TWT responding STA has already transmitted a nonzero Next TWT Info/Suspend Duration field to the STA within this TWT SP, and is not otherwise required to respond with a BAT frame, TACK frame or STACK frame, the TWT responding STA may respond to the STA with a frame that contains a Next TWT Info/Suspend Duration field. When present in the response frame, the Next TWT Info/Suspend Duration field may contain the value of the TSF timer corresponding to the next scheduled TWT SP for the STA that is the intended recipient of the frame or may contain the value 0 to indicate that the Next TWT is not currently available for this TWT.

A TWT requesting STA awake for an explicit TWT SP shall not transmit a PS-Poll frame with the Poll Type subfield equal to any value other than 2.

A TWT requesting STA that is awake for an explicit TWT SP shall not enter doze state until it has received a nonzero Next TWT Info/Suspend Duration field from the TWT responding STA and has either been in the awake state for a duration of at least Nominal Minimum TWT Wake Duration from the TWT SP start time as identified by the TWT responding STA or has received an EOSP field equal to 1 from the TWT responding STA. If more than one nonzero Next TWT Info/Suspend Duration field is received from the TWT responding STA during a TWT SP, the receiving STA shall discard all but the most recently received value. If no nonzero Next TWT Info/Suspend Duration field is received from the TWT responding STA during the TWT SP, then following the end of the TWT SP when not otherwise prohibited from transmitting, the TWT requesting STA may transmit a frame that is addressed to the TWT responding STA as a means to solicit a response frame that contains a Next TWT value. Examples of frames that solicit a Next TWT Info/Suspend Duration field include

— A TWT Information frame with the TWT Flow Identifier subfield equal to the TWT Flow Identifier corresponding to the TWT agreement for which a Next TWT value is requested and with the Next TWT Size subfield equal to 0, soliciting a STACK frame response.
— An A-MPDU containing a TWT Information frame with the TWT Flow Identifier subfield equal to the TWT Flow Identifier corresponding to the TWT agreement for which a Next TWT value is requested and with the Next TWT Size subfield set to 0, soliciting a BAT frame response.
— An S-MPDU containing a TWT Information frame with the TWT Flow Identifier subfield equal to the TWT Flow Identifier corresponding to the TWT agreement for which a Next TWT value is requested and with the Next TWT Size subfield equal to 0, soliciting a TACK frame response.

A TWT requesting STA that transmits a PPDU containing a TWT Information frame receives a response frame that can include a Next TWT field, as indicated above, and therefore, is not required to set the value of the Next TWT Request subfield to 1 to solicit the response of a TWT Information frame that includes a Next TWT field.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

During an explicit TWT SP, a TWT responding STA that has transmitted a frame containing a Next TWT subfield equal to 0 shall queue for transmission at least one frame to the same recipient containing the nonzero Next TWT corresponding to the TWT Flow Identifier indicated in the frame with the Next TWT subfield equal to 0.

If a TWT requesting STA has transmitted a frame soliciting a response that contains a Next TWT value and the STA is in a Power Save mode, the STA shall remain in the awake state following the transmission until it receives a response from the TWT responding STA that contains a nonzero Next TWT value. The TWT responding STA shall assume that the TWT requesting STA is in the doze state if the TWT requesting STA is in a Power Save mode, the TWT SP has ended and the TWT responding STA has not received a frame from the TWT requesting STA that solicits a response that contains a nonzero Next TWT value. If a TWT responding STA receives a TWT Information frame from a TWT requesting STA with the Next TWT Request subfield equal to 1, then the TWT responding STA shall queue for transmission a TWT Information frame that contains a nonzero Next TWT value corresponding to the TWT Flow Identifier of the received TWT Information frame and shall assume that the TWT requesting STA is in the awake state until the TWT responding STA has transmitted the frame containing the nonzero Next TWT value.

A TWT responding STA may include a nonzero Next TWT value in any TACK frame or STACK frame or BAT frame that is transmitted as a response to a TWT requesting STA.

The TWT responding STA shall include the initial TWT SP start time for an explicit TWT agreement in the Target Wake Time field of the TWT element, which contains a value of Accept TWT in the TWT Setup Command field, a value of 0 in the Implicit bit and the TWT Flow Identifier value corresponding to that TWT agreement in the TWT Flow Identifier subfield.

10.46.4 Implicit TWT operation

The TWT values for an implicit TWT are periodic. A TWT requesting STA operating with an implicit TWT agreement shall determine the next TWT SP start time by adding the value of TWT Wake Interval associated with this TWT agreement to the value of the start time of the current TWT SP. A TWT requesting STA operating with an implicit TWT agreement with a TWT flow identifier that matches the TWT flow identifier of a received TWT Information frame from its TWT responding STA shall replace its next TWT SP start time value with the value from the Next TWT subfield of the TWT Information frame.

The TWT responding STA shall include the start time for a series of TWT SPs corresponding to a single TWT Flow Identifier of an Implicit TWT agreement in the Target Wake Time field of the TWT element which contains a value of Accept TWT in the TWT Setup Command field and the TWT Flow Identifier value corresponding to that TWT agreement in the TWT Flow Identifier subfield. The start time of the TWT SP series indicates the beginning time of the first TWT SP in the series. Subsequent TWT SPs start times are determined by adding the value of TWT Wake Interval to the current TWT SP start time.

A TWT requesting STA awake for an implicit TWT SP may transition to the doze state after a duration AdjustedMinimumTWTWakeDuration has elapsed from the TWT SP start time as identified by the TWT requesting STA or after receiving an EOSP field equal to 1 from the TWT responding STA, whichever occurs first.

A TWT responding STA that receives a frame from a TWT requesting STA with which it has established an implicit TWT agreement may respond to the STA with a frame that contains a Next TWT Info/Suspend Duration field (e.g., BAT frame, TACK frame, STACK frame). A TWT requesting STA that is awake for an implicit TWT SP and receives a frame with a Next TWT Info/Suspend Duration field from its TWT responding STA shall use the received Next TWT Info/Suspend Duration field value as the start of the next TWT, instead of the TWT value calculated by adding the value of TWT Wake Interval associated with the TWT SP to the current TWT. Subsequent TWT start times associated with the same TWT agreement are calculated based on the next TWT that was sent by the TWT responding STA.

10.46.5 TWT grouping

An AP may include an S1G STA as a member of a TWT group if the STA indicated TWT requester support and indicated support for TWT grouping in the S1G Capabilities Information field in the S1G Capabilities element in its (Re)Association Request frame and may signal TWT times to that STA using the TWT Group Assignment field of the TWT element.

An AP shall not include a non-S1G STA within a TWT group.

When dot11TWTGroupingSupport is true, the AP may assign a TWT group ID to a TWT requesting STA when the TWT Grouping Support subfield is equal to 1 within the S1G Capabilities element received from that STA. The AP indicates the TWT value to the TWT requesting STA that supports TWT grouping by transmitting to the STA an individually addressed frame containing a TWT element, which includes

— The value of the assigned group ID in the TWT Group ID subfield.
— The lower 48 bits of a TSF value in the Zero Offset of Group subfield to indicate the TWT value corresponding to the first member of the TWT group that is identified by the TWT group ID.
— A TWT unit value in the TWT Unit subfield (9.4.2.198).
— A positive offset value indicated in the TWT Offset subfield (9.4.2.198). The allowed values in the TWT Unit subfield are given in Table 9-349.

The intended recipient of the frame containing the TWT element calculates its TWT from the TWT Group Assignment field by multiplying the TWT Unit interpretation value with the value indicated in the TWT Offset subfield and adding the result to the value in the Zero Offset of Group field corresponding to the TWT Group ID subfield in the TWT Group Assignment field of the TWT element.

10.46.6 NDP paging setup

This subclause defines a protocol for power saving at a STA by using the TWT protocol to set up scheduled wakeup intervals and by defining efficient signaling for the presence of BUs and synchronization.

A frame including a TWT element with the NDP Paging field present is referred to as NDP paging request or NDP paging response as clarified later. A STA sending an NDP paging request is referred to as NDP paging requester. A STA sending an NDP paging response in a response to an NDP paging request is referred to as NDP paging responder.

A STA requests an NDP Paging TWT by sending an NDP paging request. A non-S1G STA shall not transmit NDP Paging frames.

The setup procedure follows the protocol described in 10.46.1, unless otherwise described in this subclause.

A non-AP STA sending an NDP paging request shall set the P-ID field of the NDP paging request to one of the partial AIDs assigned to it by the intended receiver of the NDP paging request (see 10.21).

An AP sending an NDP paging request to a non-AP STA should set the P-ID field of the NDP paging request to the partial BSSID.

A SIFS after receiving an NDP paging request, the recipient STA shall respond with an NDP paging response with the NDP Paging fields set as follows:

— The P-ID subfield should be set to the same value as the P-ID subfield of the NDP paging request.
— The Max NDP Paging Period subfield shall be set to any value that is less than or equal to the Max NDP Paging Period subfield of the NDP paging request.
— The Action subfield shall be set to one of the values in Table 9-350.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The Partial TSF Offset subfield and Min Sleep Duration subfield are reserved.

The NDP paging setup is successful if the TWT Setup Command subfield of the Request Type field in the NDP paging response is equal to 4 (Accept TWT), otherwise the setup is considered as failed.

A STA that has sent an NDP paging response with the TWT Setup Command field equal to 4 (Accept TWT) shall schedule an NDP Paging frame as the first frame for transmission at the TWTs indicated by the NDP paging response, if any of the following conditions is satisfied:

— There are BUs for the requesting STA.
— No NDP Paging frame was sent in the *N* consecutive preceding TWT(s), where *N* is equal to the value of the Max NDP Paging Period subfield in the NDP paging response.

Otherwise the STA shall not schedule an NDP Paging frame.

The AP shall schedule an NDP Paging frame if there are critical updates to the S1G Beacon frame as defined in 10.45.2 and 11.2.3.14. An AP may additionally send an NDP Paging frame at any of the TWTs indicated by the NDP paging response.

If the NDP Paging frame is sent by the AP to the NDP paging requester then this frame shall precede any frame that is sent by the AP to it during its indicated TWT SP and shall have the Direction field equal to 1.

If any frame is sent by a non-AP STA to an NDP paging requester during its indicated TWT SP then the first frame sent shall be an NDP Paging frame with the Direction field equal to 0.

The P-ID field of an NDP Paging frame shall be set to the same value as the P-ID field in the NDP paging response. The P-ID field shall be set to 0 to indicate the presence of group addressed BUs.

NOTE—When a group AID is assigned to the corresponding group address as described in 10.54, then the P-ID field can be set to the partial AID that corresponds to the group AID as defined in 10.21.

If the Direction field of the NDP Paging frame is equal to 1, the subfields of the APDI field of the NDP Paging frame shall be set as follows:

— The PTSF subfield is set to TSF[Partial TSF Offset + 4 : Partial TSF Offset + 11], where TSF is the 8-octet value of the TSF timer and Partial TSF Offset is the value of the Partial TSF Offset field in the NDP paging request.
— The Check Beacon Flag subfield shall be set to the LSB of the Change Sequence field in the most recently transmitted S1G Beacon frame or of the Check Beacon field in the most recently transmitted TIM frame, if any was sent before the NDP Paging frame.

If the Direction field of the NDP Paging frame is equal to 0, the Partial AID field of NDP Paging frame indicates the partial AID of the STA transmitting the NDP Paging frame.

If no NDP Paging frame is received during the TWT, the TWT requester STA may transition to doze state at the end of the Nominal Minimum TWT Wake Duration for the TWT. If an NDP Paging frame is received, the TWT requester STA may transition to doze state immediately after receiving the NDP Paging frame, unless Min Sleep Duration field was equal to 0 and Action subfield equal to 1 in the NDP paging response that successfully completed the NDP paging setup, in which case the STA shall be in active mode.

Upon reception of an NDP Paging frame with the P-ID field matching the value of the P-ID field in the NDP paging response, the NDP paging requester shall behave as follows:

— If the Action subfield of the NDP paging response is 0:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

  - If the NDP paging requester is a non-AP STA, it shall send a (NDP) PS-Poll frame or uplink trigger frame addressed to the NDP paging responder, after either SIFS or using EDCA within Nominal Minimum TWT Wake Duration.
  - If the NDP paging requester is an AP, it shall send an NDP CTS frame to self with the duration field equal to 0 after either SIFS or using EDCA within Nominal Minimum TWT Wake Duration.
- If the Action subfield of the NDP paging response is 1, the STA shall be in the awake state starting at a time indicated by the Min Sleep Duration field after the end of reception of the NDP Paging frame, and it shall remain in the awake state until a frame is received from the NDP paging responder with the EOSP subfield equal to 1.
- If the Action subfield of the NDP paging response is 2, the STA shall be in the awake state at the first TBTT that occurs after a time indicated by the Min Sleep Duration field in the NDP paging response after the end of reception of the NDP Paging frame to receive the S1G Beacon frame.
- If the Action subfield of the NDP paging response is 3, the STA shall be in the awake state at the first DTIM beacon that happens after a time indicated by the Min Sleep Duration field in the NDP paging response after the end of reception of the NDP Paging frame to receive the DTIM beacon.
- If the Action subfield of the NDP paging response is 4, the STA shall be in the awake state starting at a time T after the end of reception of the NDP Paging frame and it shall remain in the awake state until a frame is received from the NDP paging responder with the EOSP subfield equal to 1. The value of T is in units of SIFS and is equal to the value of the Min Sleep Duration field of the NDP paging request plus the value of the ASD subfield in the APDI field of the NDP Paging frame.

If the NDP paging requester is an AP, values 2–7 of the Action subfield are reserved.

A non-AP STA that has set up NDP Paging and receives an NDP Paging frame with Direction field equal to 1 and the Check Beacon Flag subfield value different from the LSB of the most recently received Change Sequence value shall either be awake to receive the next S1G Beacon frame that is transmitted at a TBTT or TSBTT or shall queue for transmission a Probe Request frame to obtain the updated system information as described in 10.45.2.

10.46.7 TWT Sleep setup

A Responder PM Mode bit in the Control field of the TWT response equal to 1 indicates that the Responder STA may be in doze state outside the indicated TWT SP.

10.46.8 TWT teardown

Either STA that is a party to an established TWT agreement may delete the TWT agreement by successfully transmitting a TWT Teardown frame. The TWT Flow Identifier field of the TWT Teardown frame shall be set to the value of the TWT Flow Identifier field of the TWT element of the frame that successfully concluded the setup of the TWT agreement that is the subject of the teardown request.

When a TWT Teardown frame is successfully transmitted or received, the TWT agreement corresponding to the TWT Flow Identifier field, TWT requesting STA MAC address and TWT responding STA MAC address of the TWT Teardown frame shall be deleted.

10.46.9 TWT parameter ranges

A STA that supports receiving two TWT elements in a TWT Setup frame sets the TWT Parameters Range Support field to 1 in the Extended Capabilities elements that it transmits.

A TWT requesting STA may send a TWT request that contains two TWT elements to a TWT responding STA if it has received an Extended Capabilities element from the TWT responding STA with the TWT

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Parameters Range Support field equal to 1. The TWT requesting STA shall either set the TWT Setup Command fields of the two TWT elements to Suggest TWT or set the TWT Setup Command fields of the two TWT elements to Demand TWT.

A TWT responding STA may send a TWT response that contains two TWT elements to a TWT requesting STA if it has received an Extended Capabilities element from the TWT requesting STA with the TWT Parameters Range Support field equal to 1. The TWT responding STA shall either set the TWT Setup Command fields of the two TWT elements to Alternate TWT or set the TWT Setup Command fields of the two TWT elements to Dictate TWT.

If a STA sends a TWT request or a TWT response with two TWT elements:

— It shall set the TWT Flow Identifier field or the Broadcast TWT ID field of the two TWT elements to the same value.

— For a TWT parameter of the proposed TWT agreement that is carried in the Target Wake Time field or Nominal Minimum TWT Wake Duration field, and for the TWT wake interval parameter, the STA may indicate either a single value or a range of values. For other TWT parameters, the STA shall indicate a single value. To indicate a single value for a parameter, the STA sets the value of that parameter to be the same in each TWT element. To indicate a range of values for a parameter, the STA sets the value of that parameter differently in each TWT element. The range indicated for a parameter is the range that starts with the lower value and includes all values up to the higher value, irrespective of their order in the TWT elements, except for the TWT Wake Interval Mantissa and the TWT Wake Interval Exponent fields. The range indicated for the TWT wake interval begins with the lower value of the two TWT wake interval values and ends with the higher value of the two TWT wake interval values, where the TWT wake interval is determined from the TWT Wake Interval Mantissa and TWT Wake Interval Exponent fields as specified in 9.4.2.198.

If a TWT requesting STA sent a TWT request that contains two TWT elements to a TWT responding STA, the TWT responding STA shall set each TWT parameter of the TWT response to a value selected from the range of values provided in the TWT request, if the TWT Setup Command field of the TWT response is Accept TWT and the parameter included a range in the corresponding TWT request.

If a TWT responding STA sent a TWT response that contains two TWT elements to a TWT requesting STA with a TWT Setup Command field value of Dictate TWT, that response implies that a TWT agreement is likely to be accepted only if the requesting STA transmits a new TWT request with the TWT parameters set to a value selected from the range of values provided in the TWT response. If a TWT responding STA sent a TWT response that contains two TWT elements to a TWT requesting STA with a TWT Setup Command field value of Alternate TWT, that response implies a counter-offer of TWT parameters by the TWT responding STA, which can be indicated in the form of a range of values (although alternative TWT parameters might be accepted as well).

10.47 Non-TIM operation

10.47.1 Resource protection for S1G STAs in non-TIM mode

10.47.1.1 General

Resource protection for S1G STAs in non-TIM mode allows an AP to protect specific times for participating S1G STAs in non-TIM mode from medium access by S1G STAs in TIM mode. The objective of this procedure is to minimize contention between S1G STAs in non-TIM mode and S1G STAs in TIM mode and thus reduce power consumption of S1G STAs in non-TIM mode caused by medium contention with S1G STAs in TIM mode. For this purpose, an AP may set up RAW(s) for S1G STAs in non-TIM mode and then indicate to S1G STAs in TIM mode RAW information during which no S1G STA in TIM mode is allowed

to contend. The RAW(s) are used for protecting either TWT(s) scheduled by the AP or specific interval(s) for S1G STAs in non-TIM mode.

When an AP schedules TWT(s) for S1G STAs in non-TIM mode, the AP may set up RAW(s) to protect the TWT(s) for S1G STAs in non-TIM mode. The AP may schedule more than one TWT for S1G STAs in non-TIM mode so that it can set up a RAW which covers the interval summing up the duration indicated by the corresponding Nominal Minimum TWT Wake Duration field assigned to each S1G STA in non-TIM mode in a sequence.

An AP is a TWT-protection capable AP if it sets both dot11RAWOperationActivated and dot11TWTOptionActivated to true.

An S1G STA in non-TIM mode with dot11TWTOptionActivated equal to true may request for the TWT protection for a TWT-protection capable AP when it sets up a TWT agreement with the AP. In the TWT setup procedure specified in 10.46.1, an S1G STA in non-TIM mode transmits a TWT element in a (Re)Association Request frame or a TWT Setup frame to the AP, and the S1G STA in non-TIM mode may request for a TWT protection by setting the TWT Protection subfield in the Request Type field of the TWT element (9.4.2.198) to 1. If the protection is not required by the S1G STA in non-TIM mode, the TWT Protection subfield shall be set to 0.

When a TWT-protection capable AP receives a TWT element from an S1G STA in non-TIM mode with the TWT Protection subfield equal to 1 during the TWT setup procedure, it is recommended that the AP allocates RAW(s) to protect the TWT SPs corresponding to the particular TWT Flow Identifier.

When a TWT-protection capable AP receives a TWT element from an S1G STA in non-TIM mode during the TWT setup procedure and if the AP can guarantee to protect the scheduled TWT(s) for the S1G STA in non-TIM mode by allocating RAW(s), it shall set the TWT Protection subfield in the TWT element included in the (Re)Association Response frame or a TWT Setup frame that is transmitted to the STA during the TWT setup procedure to 1. If the AP cannot guarantee to protect the scheduled TWT(s) by allocating RAW(s), it shall set the TWT Protection subfield in the TWT response to 0.

After a TWT-protection capable AP has successfully completed the TWT setup as described in 10.46.1 and if the AP has set the TWT Protection subfield in the TWT element to 1 during the TWT setup procedure with the STA, the AP shall set up RAW(s) that covers at least the duration indicated by the Nominal Minimum TWT Wake Duration field (9.4.2.198) assigned to the S1G STA in non-TIM mode. If the AP has set the TWT Protection subfield to 0, the AP may set up RAW(s) that covers at least the duration indicated by the Nominal Minimum TWT Wake Duration field.

To protect contention for medium access for an S1G STA in non-TIM mode, an AP with dot11RAWOperationActivated equal to true may schedule TWTs within a RAW that is not assigned to any S1G STA in TIM mode. When the AP is polled by TWT STAs that were not scheduled during the RAW duration, the AP may reschedule their awake/doze cycle as described in 10.47.2.

The AP uses either generic RAW(s) or non-TIM RAW(s) for protecting S1G STAs in non-TIM mode:

— In a generic RAW, medium access is only allowed to a group of STAs indicated by the RAW Group field as specified in 10.23.5.4.

In a non-TIM RAW, the RAW Group field is not present and medium access is only allowed to S1G STAs in non-TIM mode that are scheduled within the duration calculated from the RAW Slot Definition field as specified in 10.23.5.1.

10.47.1.2 Resource protection for S1G STAs in non-TIM mode using periodic RAW (PRAW) operation

In resource protection for S1G STAs in non-TIM mode specified in 10.47.1, PRAW, which is specified in 10.23.5.8 can be used to indicate to S1G STAs in TIM mode information related to periodically scheduled RAWs during which no S1G STAs in TIM mode are allowed to contend.

An example of a basic operation of a PRAW allocation is shown in Figure 10-140 (Example of PRAW operation). In this figure, PRAW is allocated at every short beacon interval, but the allocation of the PRAW is indicated at every DTIM beacon. STA1 is an S1G STA in TIM mode that is not included in the PRAW allocation and STA2 is an S1G STA in non-TIM mode for which the AP has scheduled TWT and is included in the PRAW allocation. When STA1 listens to the Beacon frame, it can identify the allowed user group, start time, duration, and the periodicity of the allocated PRAW. As STA1 is not included in the allowed user group of the PRAW, STA1 will not access the channel during the allocated PRAW, which is indicated in the S1G Beacon frame that is transmitted every short beacon interval. And, STA2 wakes up at its scheduled TWT, which is within the PRAW, and send its uplink data if it has a Data frame to send.

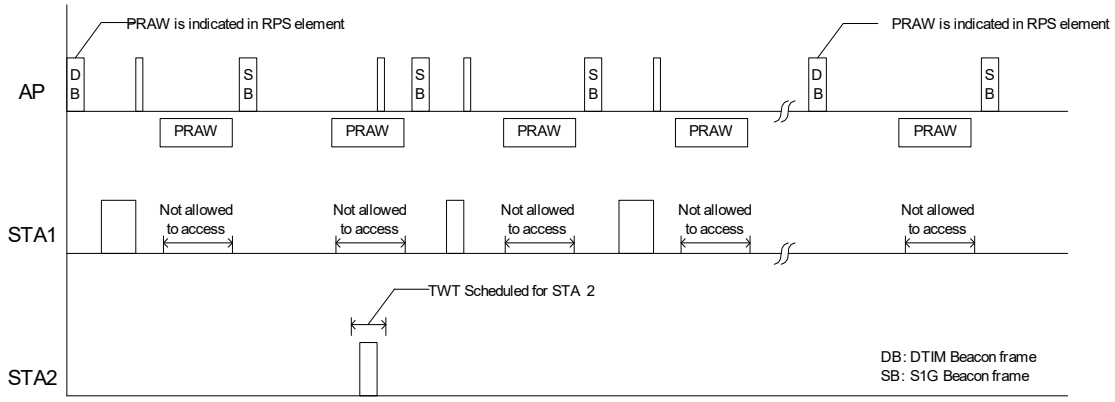

Figure 10-140—Example of PRAW operation

10.47.2 Rescheduling of awake/doze cycle

This subclause defines a procedure for the S1G AP to reschedule the awake/doze cycle of an S1G STA in Non-TIM Mode.

An S1G STA in non-TIM mode that transmits a PS-Poll frame may set the Poll Type subfield of the Frame Control field to

- 0 if it requests to the AP delivery of DL BUs but without a request for rescheduling of the awake/doze cycle.
- 1 if it solicits information regarding the change sequence of the Beacon and the partial timestamp.
- 2 if it is not a TWT STA and requests to the AP delivery of the DL BUs and resynchronizing to the next TBTT.
- 2 if it is a TWT requester STA that transmits the frame to the TWT responder AP within the negotiated TWT SP to request delivery of DL BUs and information for the next TWT.
- 3 if it requests to the AP to reschedule its doze/wake cycle to another service period.

Upon receiving an NDP PS-Poll frame, trigger frame or PS-Poll frame with the Poll Type subfield equal to 0 sent by an S1G STA, the S1G AP responds as described in 11.2.3.6.

NOTE—The S1G STA can be an S1G STA in TIM mode or an S1G STA in non-TIM mode.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Upon receiving a PS-Poll frame with the Poll Type subfield not equal to 0 sent by an S1G STA in non-TIM mode, the AP responds with different frames depending on the value of the Poll Type subfield in the Frame Control field of the PS-Poll frame that elicited the response as follows:

- If the Poll Type subfield is equal to 1 then the AP with dot11PollTACKResponseImplemented equal to true shall respond with a TACK frame that does not contain the Next TWT Info/Suspend Duration field. An S1G STA shall not send a PS-Poll frame with the Poll Type subfield equal to 1 to an AP unless the TACK Support as PS-Poll Response field of the S1G Capabilities element received from that AP is equal to 1.
- If the Poll Type subfield is equal to 2 and is sent by a TWT requester STA within the negotiated TWT SP then the AP responds with a TACK frame as described in 10.46. A TWT requester STA shall not send a PS-Poll frame with the Poll Type subfield equal to 2 to an AP unless the TWT Responder Support field of the S1G Capabilities element received from that AP is equal to 1.
- If the Poll Type subfield is equal to 2 and is either sent by a STA that is not a TWT requester STA or is sent by a TWT requester STA not within the negotiated TWT SP then the AP shall either respond with the DL BU or with an NDP Ack frame. The NDP Ack frame may include a wakeup timer value (i.e., its Idle Indication field is equal to 1), which expires at the next TBTT.
  - The AP may also respond with a control response frame that includes a Duration field that indicates a wakeup timer (i.e., an NDP Ack or NDP PS-Poll-Ack frame with Idle Indication field equal to 1) if it receives a trigger or NDP PS-Poll frame from an S1G STA in non-TIM mode, which satisfies the criteria above.
  - The S1G STA in non-TIM mode may resynchronize to the S1G Beacon frame with the help of the wakeup timer.
- If the Poll Type subfield is equal to 3, then the AP may respond with an NDP Ack frame that includes a wakeup timer as described in 11.2.3.6:
  - If the STA has requested time slot protection and the AP is UL-Sync capable, then the AP shall protect the TXOP duration following the expiration of the wakeup timer as described in 10.48.
  - A UL-Sync capable AP may also respond with a control response frame that includes a Duration field that indicates a wakeup timer (i.e., an NDP Ack or NDP PS-Poll-Ack frame with Idle Indication field equal to 1) if it receives a trigger or NDP PS-Poll frame from an S1G STA in non-TIM mode that satisfies the criteria above.

The S1G AP shall set More Data field to 1 in the responding control frame if there is a BU buffered for the non-TIM S1G STA. If the non-TIM S1G STA receives a responding control frame in which the Idle Indication field is equal to 1 and the Duration field is a nonzero value, there is no frame transmission for the STA in the indicated duration in which the S1G STA may enter the doze state. After an amount of time that is equal to the value in the Duration field, it shall be in the awake state.

An S1G AP may set the wakeup timer (Duration field) as the duration to a TBTT in the responding control frame (either NDP Ack frame or NDP PS-Poll-Ack frame) and treat the S1G STA in non-TIM mode as an S1G STA in TIM mode starting from the TBTT if the bit corresponding to the S1G STA in non-TIM mode in the traffic indication virtual bitmap is equal to 1 and the STA has indicated support for temporary PS mode switch by setting the Temporary PS Mode Switch subfield to 1 in the S1G Capabilities element it transmitted to the AP. After the amount of time that is equal to the Duration field value in the responding control frame from the S1G AP, the non-TIM S1G STA shall transition to awake state to receive a Beacon frame. Upon receiving the Beacon frame, the S1G STA in non-TIM mode infers from the TIM element indicating that there is BU for it that it is treated as an S1G STA in TIM mode and operates as an S1G STA in TIM mode from then on, setting dot11NonTIMModeActivated to false and switching to TIM mode (see 11.2.3.2). The S1G STA returns to the S1G STA in non-TIM mode operation mode by setting dot11NonTIMModeActivated to true if the S1G AP indicates that there is no more data buffered for the S1G STA and the S1G STA indicates to the S1G AP that there is no more data to transmit. The S1G AP treats the S1G STA as an S1G STA in non-TIM mode if the STA indicates that there is no more data to transmit and the S1G AP indicates that there is no more data buffered for the STA.

10.48 Sync frame operation

This subclause describes a sync frame transmission procedure for uplink traffic, which minimizes the time for medium synchronization for a STA that is changing from doze state to awake state in order to transmit. The sync frame is a frame that solicits a Data frame as an immediate response, if any is available, from the receiving STA.

When performing the Sync frame operation described in this subclause, if management frame protection is negotiated and both STAs set the Extended S1G Action Protection field in the RSNXE that they transmit to 1, the STAs shall:

— use individually addressed Protected Sync Control frames instead of Sync Control frames and
— discard any individually addressed Sync Control frames received from the peer STA, with which management frame protection is negotiated.

STAs that exchange individually addressed Protected Sync Control frames shall follow the rules defined in 12.6.17.

When management frame protection is not negotiated or the Extended S1G Action Protection field in the RSNXE transmitted by either STA is 0, the STAs shall not use the Protected Sync Control frame.

If dot11S1GUplinkSyncOptionImplemented is true, an AP shall set the Uplink Sync Capable field in the S1G Capabilities element to 1. If dot11S1GUplinkSyncOptionImplemented is false, the AP shall set the Uplink Sync Capable field in the S1G Capabilities element to 0.

An AP is a UL-Sync (Uplink Sync) capable AP if it sets the Uplink Sync Capable field to 1.

A STA may request a UL-Sync capable AP to transmit a sync frame at the slot boundary of the STA in a RAW or at the target wake time of the STA.

A STA may request for a sync frame transmission to the UL-Sync capable AP either during association by sending a (Re)Association Request frame in which the Uplink Sync Capable field in the S1G Capabilities element is equal to 1 or at any time by sending a Sync Control frame (an Action frame of category S1G) in which the Uplink Sync Request field in the Sync Control field is equal to 1.

A STA may request the UL-Sync capable AP to stop the sync frame transmission at any time by sending a Sync Control frame in which the Uplink Sync Request field in the Sync Control field is equal to 0.

When a STA is requesting for a sync frame transmission, a STA may also request an AP to protect a RAW slot in a RAW defined in the Slot Duration field (9.4.2.190) or a duration at a TWT defined in the Nominal Minimum TWT Wake Duration field (9.4.2.198), or by setting the Time Slot Protection Request field in the Sync Control field to 1. A STA may also request an AP protection for a TXOP duration after the expiration of a wakeup timer as described in 10.47.2. The time slot protection is not requested if the Time Slot Protection Request field is equal to 0. When an AP receives a Sync Control frame from a STA with the Time Slot Protection Request field equal to 1, the AP shall protect a time slot that is assigned for the STA in a RAW, or a duration that is assigned for the STA at a TWT, or a TXOP duration after the expiration of a wakeup timer of the STA with NAV-setting frame exchange sequences. Note that NAV-setting frame exchange sequences refer to any frame that can set NAV to other third-party stations, and an AP has the flexibility to choose any NAV-setting frame exchange sequences for protection.

For a STA that requested for a sync frame transmission, the UL-Sync capable AP shall schedule a sync frame at the slot boundary of the STA in the RAW if the Time Slot Protection Request field is equal to 1 or the Cross Slot Boundary field is equal to 1, or at the TWT of the STA, or at the expiration of the wakeup timer, as the next frame for transmission according to the medium access rules specified in Clause 10.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the medium is busy at the slot boundary of a STA in the RAW or at the TWT of the STA, or at the expiration of the wakeup timer, or if the UL-Sync capable AP determines that the remaining time in the RAW slot or the TWT SP, or the TXOP duration to be too short to transmit a sync frame, the UL-Sync capable AP shall cancel the scheduled sync frame transmission. When the STA is changing from doze state to awake state in order to transmit, the STA shall follow the rules defined in 11.2.3.2.

The UL-Sync capable AP should use an NDP CTS frame as a sync frame. The AP may use any NAV-setting frame as a sync frame provided that the frame solicits a Data frame as an immediate response from the receiving STA (e.g., a reverse direction grant).

When a STA receives an NDP CTS frame with the RA/Partial BSSID field equal to the S1G partial AID of the STA from the UL-Sync capable AP with which the STA is associated, the STA shall transmit a Data frame to the AP a SIFS after the reception of the NDP CTS frame if the STA has a Data frame to transmit to the AP and has requested the AP for a sync frame transmission. When a STA receives an NDP CTS frame with the RA/Partial BSSID field not equal to the S1G partial AID of the STA, the STA shall follow the NAV setting rules defined in 10.3.2.4.

After transmitting the sync frame, the AP shall wait for an AckTimeout interval (as defined in 10.3.2.11), starting at the PHY-TXEND.confirm primitive. If a PHY-RXEARLYSIG.indication or PHY-RXSTART.indication primitive does not occur during the AckTimeout interval, the AP may transmit a CF-End frame or an NDP CF-End frame to reset the NAV provided that the remaining duration is long enough to transmit this frame.

For a STA requesting for a sync frame transmission with the Time Slot Protection Request field set to 0, the AP should not send a sync frame at each slot boundary within a RAW period if the Cross-Slot Boundary field is equal to 0.

Figure 10-141 (Example of uplink sync frame transmission procedure in RAW) illustrates an example of the uplink sync frame transmission procedure in a RAW. STA1 is allocated Slot1 in the RAW and STA2 is allocated Slot3 in the RAW. Both STA1 and STA2 have requested the UL-Sync capable AP to transmit a sync frame at the slot boundary. At the slot boundary of Slot1, the medium is idle and thus the AP transmits a sync frame at the slot boundary. However, at the slot boundary of Slot3, the medium is busy and thus the AP cancels the scheduled sync frame transmission for STA2.

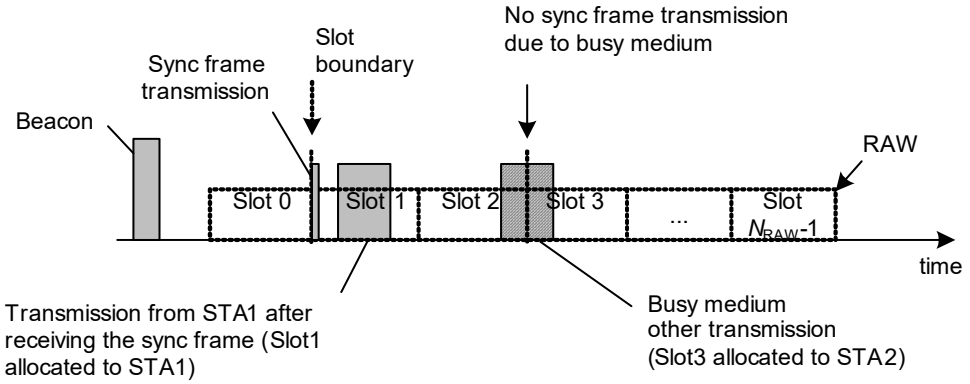

Figure 10-141—Example of uplink sync frame transmission procedure in RAW

10.49 Bidirectional TXOP

10.49.1 Overview

Bidirectional TXOP (BDT) allows an S1G AP and a non-AP S1G STA to exchange a sequence of uplink and downlink PPDUs separated by SIFS. This operation combines both uplink and downlink channel access into a continuous frame exchange sequence between a pair of S1G STAs. S1G STAs that participate in BDT use information that is present in the Frame Control field, SIGNAL field and NDP CMAC PPDUs to signal an undergoing BDT as described in 10.49.2. The objective of this operation is to minimize the number of contention-based channel accesses, improve channel efficiency by reducing the number of frame exchange sequences, and reduce S1G STA power consumption by shortening awake state times.

An S1G STA with dot11BDTImplemented equal to true shall set the BDT Capable field in the S1G Capabilities element to 1. An S1G STA with dot11BDTImplemented equal to false shall set the BDT Capable field in the S1G Capabilities element to 0. An S1G STA shall not use the BDT procedure to transmit frames to another S1G STA whose BDT Capable field is equal to 0.

10.49.2 Rules for BDT

Throughout this subclause, an S1G STA signals a Response Indication of Long Response by setting the TXVECTOR parameter RESPONSE_INDICATION to Long Response for non-NDPs and by setting the Idle Indication field to 1 and the Duration field to 0 for NDP (PS-Poll-)Ack frames. The S1G STA signals a Response Indication of No Response by setting the TXVECTOR parameter RESPONSE_INDICATION to No Response for non-NDPs or by setting the Idle Indication field to 0 and the Duration field to 0 for NDP (PS-Poll-)Ack frames. The S1G STA signals a Response Indication of Normal Response by setting the TXVECTOR parameter RESPONSE_INDICATION to Normal Response for non-NDPs.

An S1G AP may initiate a BDT exchange with an NDP PS-Poll-Ack frame that is sent as a response to an NDP PS-Poll frame. A non-AP S1G STA shall not initiate a BDT exchange with a PS-Poll frame unless it is a PS-Poll+BDT frame with the More Data field equal to 1. A BDT exchange consists of one or more BDT sequences.

A BDT sequence comprises the following:

a) The transmission of one PPDU that is either an NDP PS-Poll-Ack frame or satisfies the following conditions:
   1) Contains a Response Indication of Long Response
   2) Follows the same rule as the initial frame for TXOP as defined in 10.23.2 if the PPDU is the first frame sent by the BDT Initiator during this TXOP
   3) Contains a Duration/ID field that sets the NAV
   4) Contains no HT Control field with the RDG/More PPDU subfield equal to 1.

   An S1G STA that transmits this PPDU is known as a BDT Initiator.
b) The transmission of one or more PPDUs (BDT response burst) by the S1G STA addressed in the PPDUs transmitted by the BDT Initiator, separated by SIFS. Only the last (or only) PPDU of the BDT response burst may contain any MPDU requiring an immediate response. All the other PPDUs in the BDT response burst (if there are any) except the last one shall indicate “No Response” in the response indication field. The S1G STA that transmits the BDT response burst is known as the BDT Responder.
c) The transmission of one PPDU by the BDT Initiator containing an immediate response (the BDT Initiator final PPDU), if so required by the last PPDU of the BDT response burst.

NOTE 1—A BDT Initiator can include multiple BDT sequences, separated by SIFS, within a single TXOP.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 2—A BDT sequence cannot be started with a PPDU that can not signal a Response Indication, e.g., an NDP PS-Poll frame.

NOTE 3—A BDT sequence can be started with a PS-Poll+BDT frame.

The total duration of the BDT Initiator PPDUs shall not exceed the TXOP limit as described in 10.23.2.9. The BDT responder PPDU transmission(s) and any expected responses shall fit entirely within the remaining TXOP or SP duration, as indicated in the Duration/ID field of the latest MPDU transmitted by the BDT initiator. The PPDUs may carry Data frames of any TID. A BDT exchange is subject to TXOP duration limits for the current AC.

A BDT Responder sending a BDT response burst containing an immediate response to an eliciting PPDU that had the More Data field equal to 1 shall set the Response Indication to Long Response for the last PPDU in the BDT response burst.

A BDT Responder sending a BDT response burst containing an immediate response to an eliciting PPDU that had the More Data field equal to 0 shall not set the Response Indication of the last PPDU of the BDT response burst to Long Response.

A non-AP STA shall remain in the awake state until the end of the current TXOP when one of the following conditions is met:

— It is the intended receiver of a frame with More Data field equal to 1 that is sent by the AP.
— It is a BDT Initiator of a BDT sequence within a single TXOP.

A non-AP STA may transition to the doze state if it is the intended receiver of a frame with More Data field equal to 0, which is sent by the AP.

Upon receiving a PS-Poll+BDT frame with the More Data field equal to 0, in order to respond with immediate Data frames an S1G AP may use the RTS/CTS scheme to send buffered data until it transmits a frame with the More Data field equal to 0 or until the duration of the exchange, including the initial PS-Poll+BDT frame reaches the TXOP limit whichever comes first.

Figure 10-142 (Example of BDT frame exchange exchange) illustrates an example of BDT signaling. STA A initiates the BDT exchange by setting the Response Indication to Long Response in the PS-Poll+BDT frame and in the preamble of two PV0 PPDUs to allow STA B to transmit its BUs. At the end, STA B sends

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

a PPDU with the Response Indication 2 (Normal Response) and STA A terminates the BDT exchange by sending a PPDU with the Response Indication equal to 0 (No response).

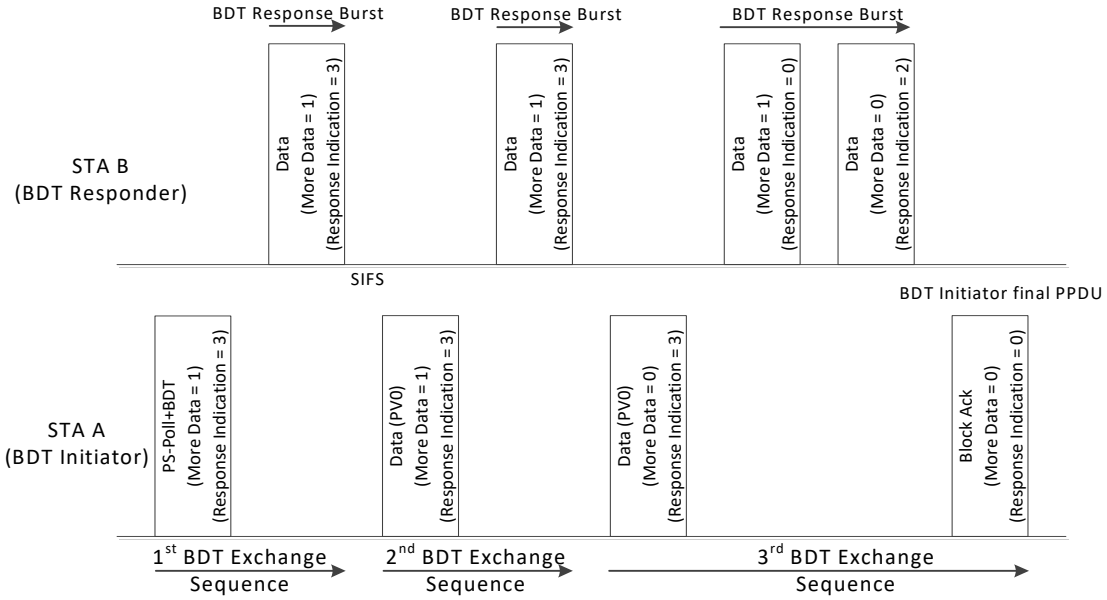

Figure 10-142—Example of BDT frame exchange exchange

NOTE 4—For error recovery, a BDT initiator can transmit the next frame when the CS mechanism (see 10.3.2.1) indicates that medium is idle at TxPIFS slot boundary (defined in 10.3.7).

10.50 Page slicing

An S1G STA with dot11PageSlicingImplemented equal to true shall set the Page Slicing Support field in the S1G Capabilities element to 1. An S1G STA with dot11PageSlicingImplemented equal to false shall set the Page Slicing Support field in the S1G Capabilities element to 0.

If an S1G STA supports the page slicing mechanism as defined in this subclause, then it shall set dot11PageSlicingImplemented to true. Otherwise, an S1G STA that does not support the page slicing mechanism or a non-S1G STA shall set dot11PageSlicingImplemented to false.

The TIM element indicates downlink buffered data for all STAs in the BSS. However, in an S1G BSS with a large number of associated STAs corresponding to a single TIM and page, a single TIM element indicating the downlink buffered data for all STAs in the page can be quite large. To reduce the size of the element needed to communicate buffered data status to power save S1G STAs, an S1G AP may send one portion of a page in the TIM element virtual bitmap of each Beacon frame if dot11PageSlicingActivated is true as described in this subclause.

The traffic-indication virtual bitmap in a TIM includes a subset of the blocks from a single page. This subset of blocks is called a page slice and the size of the subset is indicated in the Page Slice Length subfield of the Page Slice element (9.4.2.191). The case of 4 TIMs and their 4 assigned page slices is depicted in

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Figure 10-143 (Page slicing with Page Slice element with 4 TIMs). All page slices corresponding to a single Page Slice element shall have equal size except for the last page slice.

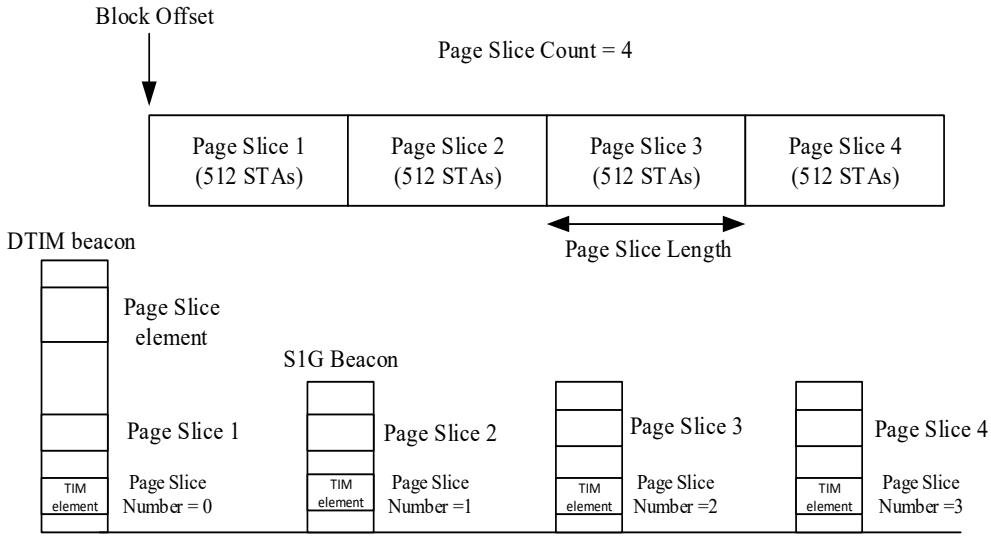

Figure 10-143—Page slicing with Page Slice element with 4 TIMs

If a TIM element contains a Bitmap Control field, an S1G STA shall examine the Traffic Indicator field, irrespective of the Page Slice Number and Page Index fields.

An S1G STA for which dot11PageSlicingImplemented is true shall process all received TIM elements that include a Page Slice Number field that matches its page slice number and a Page Index field that matches its page index, and it shall follow the rules of 11.2.3.7 if the partial virtual bitmap of any of the processed TIM elements included the value of 1 in the position corresponding to any of its AIDs.

An AP that has dot11PageSlicingActivated equal to true shall not include the bit in the partial virtual bitmap that corresponds to the AID of the S1G STA with dot11PageSlicingImplemented equal to false within a TIM element that has a value for the Page Slice Number field that is in the range 0 to 30. An AP that has dot11PageSlicingActivated equal to false shall not transmit a TIM element that has a value for the Page Slice Number field that is in the range 0 to 30.

If an AP meets the following conditions:

— Its dot11PageSlicingActivated is true.
— Has at least one associated non-AP STA from which it has received an S1G Capabilities element with the Page Slicing Support field equal to 0 within a page.

then the AP shall

— Include in all the S1G Beacons a TIM element with Page Index subfield equal to the corresponding page index and Page Slice Number field equal to 31, if there is buffered traffic for at least one of the STA(s).
— Set the bits in the virtual bitmap of that TIM for those STAs, according to the rules described in 11.2.3.6.

An AP with dot11PageSlicingActivated equal to true and that has at least one associated STA with dot11PageSlicingActivated equal to true and whose AID is contained in

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The final block (32nd block) of a page, and has indicated a Page Slice Count equal to 0 and a Page Slice Length field greater than 1 in the Page Slice Control field of the Page Slice element shall include in the last S1G Beacon frame that precedes the next scheduled DTIM beacon, a TIM element with Page Index subfield equal to the page index specified in the previously transmitted Page Slice element. The TIM element shall have the Page Slice Number field equal to 31 for the indicated page, if there is buffered traffic for at least one of the STA(s) that support page slicing and belong in the final block of the page.
— Any block of a page, and has indicated a Page Slice Count equal to 0 and a Page Slice Length field equal to 1 in the Page Slice Control field of the Page Slice element shall include in the only S1G Beacon frame that precedes the next scheduled DTIM beacon, a TIM element with Page Index subfield equal to the page index specified in the previously transmitted Page Slice element. The TIM element shall have the Page Slice Number field equal to 31 for the indicated page, if there is buffered traffic for at least one of the STA(s) that support page slicing and belong in any block of the page.

The setting of the bits in the virtual bitmap of that TIM for STAs that do not support page slicing follows the rules described in 11.2.3.6.

For each page from which an AP with a value of false for dot11PageSlicingActivated has assigned at least one AID corresponding to STA(s) for which there is buffered traffic, the AP shall include in all the S1G Beacons a TIM element for that page with Page Slice Number field equal to 31 and shall set the bits in the virtual bitmap of that TIM for all the STAs indicated by the Page Index subfield, according to the rules described in 11.2.3.6.

An AP with dot11PageSlicingActiviated equal to true may include more than one TIM representing different page slices within a Beacon frame. An AP with dot11PageSlicingActiviated equal to true shall not transmit a Page Slice element in any frame other than a Beacon frame that has DTIM count equal to 0. Each page slice corresponding to a TIM, except the last TIM, shall have a size that is equal to the Page Slice Length subfield indicated in the Page Slice element. However, the length of the page slice may vary over multiple page periods. The page period is the number of beacon intervals between successive beacons that carry the Page Slice element for the associated page. Transmission of page slices of a page can span multiple DTIM periods. The AP shall transmit the first page slice in the N-th Beacon frame after the DTIM beacon in which the Page Slice element appears, where N is equal to the TIM offset subfield. Subsequent page slices indicated in the Page Slice element appear sequentially in the following beacons, e.g., the second slice appears in (N+1)th Beacon frame after the DTIM beacon that contained the Page Slice element. A value of zero for TIM offset corresponds to the DTIM beacon. The TIMs can be flexibly scheduled for page slices of different pages over beacon intervals. Figure 10-143 (Page slicing with Page Slice element with 4 TIMs) is an illustration with 4 page slices, which appear in the DTIM beacon and the three following Beacons when the TIM Offset subfield of the Page Slice element is equal to 0.

The page period is the number of beacon intervals between successive beacons that carry the Page Slice element for the associated page. Transmission of page slices of a page can span multiple DTIM periods.

The Page slice element indicates assignment of STAs in page slices corresponding to their assigned TIMs. STAs within the assigned page slice transition to awake state at a corresponding TIM sequentially to receive buffered data from AP. In order to transition to awake state at the appropriate TBTT to receive the Page Slice element, a STA may compute the page slice assignment to the TIMs using the length of the Page Bitmap field and the value in the Page Slice Length and Page Slice Count subfields of the Page Slice element. The length of the page slice that appears in each TIM, except for the last TIM identified by a Page Slice element, is indicated in the Page Slice Length subfield. The last TIM includes the blocks indicated by the bits of the Page Bitmap field that have not appeared in previous TIMs.

An S1G STA with dot11PageSlicingActivated equal to true wakes up to receive a DTIM beacon that contains the Page Slice element for its associated page slice from the AP. The STAs check the DTIM beacon

comprising of the Page Bitmap field and the Block Bitmap fields in the Page Slice element and TIM, respectively. The Page Bitmap field in the Page Slice element provides an early indication of buffered data for all blocks in the assigned page slices. If a bit in the Page Bitmap field of the Page Slice element is equal to 0, it indicates that there is no buffered data for STAs with AIDs located in the block corresponding to that bit. These STAs may return to doze state immediately when there is no buffered group addressed data or after receiving buffered broadcast/group data as indicated in the DTIM beacon. If the block bit in the Page Bitmap field is equal to 1, then it indicates that there is buffered data at the AP for at least one of the STAs with AIDs in that block.

For STAs that have their AIDs that correspond to a block for which the bit in the Page Bitmap field of the Page Slice element is equal to 1, they compute the length of the page slice and the corresponding TIM to transition to awake state. If they are not assigned in page slice 1 that is allocated to DTIM slice, then these STAs may return to doze state immediately or after receiving buffered broadcast/group data as indicated in the DTIM beacon till their scheduled TIM.

At the assigned page slice, the STAs decode the page slice in order to determine whether there is buffered data available at the AP.

When dot11PageSlicingActivated is true, an S1G AP may use the Listen Interval field and Page Slice element information in determining the lifetime of frames that it buffers for an S1G STA in TIM mode that supports page slicing.

10.51 Subchannel selective transmission (SST)

10.51.1 SST overview

S1G STAs that are associated with an S1G AP transmit and receive on the channel or channels that are indicated by the AP as the enabled operating channels for the BSS.

An SST BSS is an S1G BSS for which the following conditions are satisfied:

a) The BSS operating channel width indicated in the Channel Width field of the S1G Operation Information element transmitted by the AP is less than or equal to 2 MHz.
b) The SST AP indicates that it enables SST operation by including the SST Operation element in the (Re)Association Response frame sent to the non-AP STA.

In an S1G BSS that is not an SST BSS, the enabled operating channels are indicated in the most recently received S1G Operation element transmitted by the AP. In an S1G SST BSS, the enabled operating channels are indicated in the most recently received SST Operation element transmitted by the AP.

An SST AP is an S1G AP with dot11SelectiveSubchannelTransmissionPermitted equal to true. During aperiodic SST operation, an SST AP indicates the set of enabled SST operating channels in an SST Operation element. During aperiodic SST operation, an SST AP indicates the subset of SST channels that SST STAs are allowed to access during a beacon interval or short beacon interval (see 11.1.3.10.2) in the SST element that is transmitted in the S1G Beacon frame that initiates that interval and/or in the Channel Indication subfield of RPS elements that include SST STAs in the RAW group. During periodic SST operation, an SST AP indicates the set of enabled SST operating channels in an SST Operation element and indicates the subset of SST channels that SST STAs are allowed to access during a beacon interval or short beacon interval in an RPS element with the Periodic RAW Indication subfield equal to 1.

An SST STA is an S1G STA that is associated with an SST AP and chooses a subset of the operating channels enabled for SST operation on which to operate in the BSS, when SST operating channels are activated by the AP as indicated in the SST element, the SST operation element, or the RPS element.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

SST STAs operating in an SST BSS are allowed to transmit on an SST channel during a beacon interval or short beacon interval only if the channel is permitted for SST use as indicated by the SST AP in an SST element included in the S1G Beacon frame that initiates that interval or as indicated by an RPS element in the case of periodic SST operation.

10.51.2 Aperiodic SST operation

An SST AP that sets up an SST BSS shall include the SST Operation element in (Re)Association Response frames sent during association. An S1G AP may include the SST Operation element in S1G Beacon frames. The SST AP indicates the set of enabled SST operating channels, the offset of the primary channel, and the channel width unit in the SST Operation element as described in 9.4.2.213. The set of enabled SST operating channels may include channels that are not in use by the BSS as specified by the SST Enabled Channel bitmap of the element. The SST AP that sets up an SST BSS shall choose the subset of allowed SST operating channels from the subset of enabled SST operating channels indicated in the SST Operation element. The set of enabled SST operating channels indicated by the AP is not static. The S1G AP may include the RPS element in S1G Beacon frames to signal additional channels allowed for SST operation within specific RAWs. The channels that are allowed for SST operation in the RPS element can be different from the channels allowed for SST operation in the SST element.

At each TBTT or TSBTT, an SST AP may send S1G Beacon frames on more than one channel from the set of enabled operating channels for the BSS either in parallel or in series or a combination of the two. A STA transmitting parallel S1G Beacons shall use either the value S1G_DUP_1M or the value S1G_DUP_2M for the TXVECTOR parameter FORMAT of the PHY-TXSTART.request primitive for the transmission. An example of Beacons sent in parallel is when one Beacon frame is transmitted with a value of S1G_DUP_2M for the TXVECTOR parameter FORMAT and a value of CBW8 for the TXVECTOR parameter CH_ BANDWIDTH in a BSS with an operating width of 8 MHz. An example of Beacons sent in series is when several different Beacons are transmitted in sequence, each with a value of S1G for the TXVECTOR parameter FORMAT and a value of CBW2 for the TXVECTOR parameter CH_ BANDWIDTH and each transmitted on a different 2 MHz subchannel in a BSS with an 8 MHz operating width. When beacons are transmitted in series, all of the beacons may be queued for transmission at TBTT or TSBTT, but only one Beacon frame is transmitted at a time. SIFS or later after any Beacon frame in the series is transmitted, another Beacon frame may be transmitted in the series, provided that normal medium access rules for the channel of transmission of the Beacon frame have been satisfied.

NOTE—When a series of S1G Beacon frames is transmitted, the AP can use the channel activity schedule of the SST element in those beacons to describe when UL transmissions are permitted by SST STAs in order to protect the beacon sequence and to avoid attempts to communicate with the AP during the beacon transmission sequence. RAW, CTS-to-self and other NAV-setting mechanisms can also be employed for this purpose.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An SST AP shall include an SST element in the S1G Beacon frame that immediately precedes a beacon interval or short beacon interval when it allows SST operation within that interval (see Figure 10-144 (Selective Subchannel Transmission channel transmission permission allocation for SST element)).

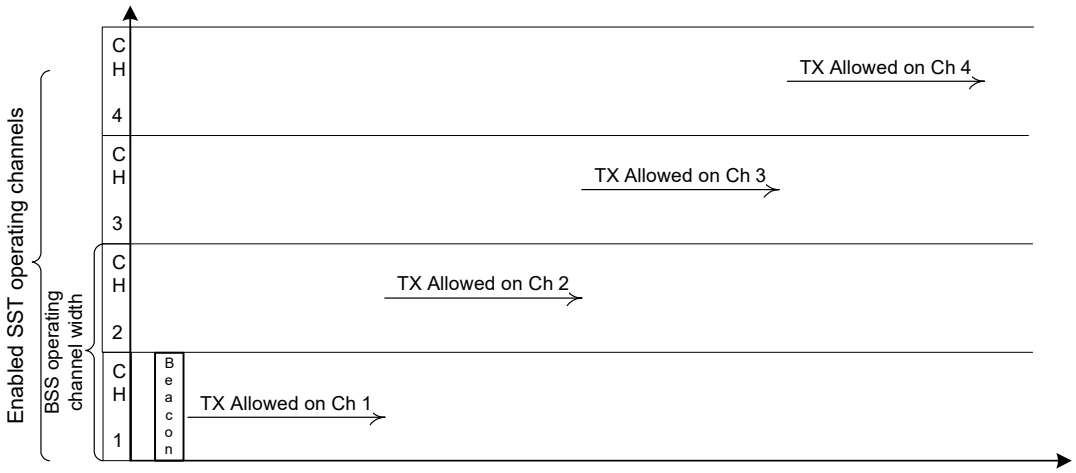

Figure 10-144—Selective Subchannel Transmission channel transmission permission allocation for SST element

An SST AP may include an SST element in transmitted S1G Beacon frames. An SST AP includes an SST element with the DL Activity bit in the SST element set to 1 and estimated start times and SST channels for DL transmissions in the Channel Activity Schedule field to indicate the expected times for the transmission of DL frames. These frames can be used by SST STAs to estimate the channel parameters which can be used as input to an algorithm for the selection of an SST channel.

The AP may transmit sounding frames to SST STAs for the purpose of estimating channel parameters. The AP may transmit sounding frames for SST STA channel estimation either in parallel or in series or a combination of the two, where a parallel transmission by an S1G AP shall use either the value S1G_DUP_1M or the value S1G_DUP_2M for the TXVECTOR parameter FORMAT of the PHY-TXSTART.request primitive for the transmission.

An S1G AP may include an SST element (see 9.4.2.200) in an S1G Beacon frame to indicate on which channels an SST STA is allowed to transmit within the BSS or SST BSS.

An S1G AP may indicate on which SST channels it intends to transmit sounding and nonsounding frames following the transmission of an S1G Beacon frame by including an SST element in the S1G Beacon frame with a nonzero value in at least one bit of the Channel Activity Bitmap subfield and a value of 1 in the corresponding DL Activity subfield. An SST STA may choose an SST channel for transmissions based on its analysis of the sounding signals and received transmissions.

In an SST BSS, an SST STA shall not transmit in a channel that is not the primary channel of the BSS if the corresponding bit of the Channel Activity Bitmap is 0 in the most recently received SST element or RPS element from its associated AP. An SST STA shall not transmit using a channel width that is greater than the value of the SST Channel Unit indicated in the most recently received SST Operation element from its associated AP.

When no SST Operation element has been received by an SST STA from its associated AP, the STA shall not transmit a frame with a BSSID that is equal to the BSSID of the BSS of which the STA is a member, in a channel of operation that is not included in the channels of operation of the BSS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the frames that are transmitted by an S1G AP in response to an announcement of transmission activity within an SST element are sounding frames, the S1G AP shall use the same value for the TXPWR_LEVEL parameter of the TXVECTOR for each of the sounding frame transmissions associated with the SST element announcement. An S1G AP should transmit SST sounding frames at times and on SST channels indicated for downlink activity in the Activity Start Time and Channel Activity Bitmap fields of the SST elements that it transmits.

The AP may signal the presence of a RAW for the purpose of SST sounding for a group of STAs using an SST sounding RAW as indicated within a transmitted RPS element. Such an SST sounding RAW may be scheduled for periodic or nonperiodic operation. Additional RAW(s) may be scheduled as SST report RAW(s) (see 9.4.2.190) after the SST sounding RAW for the transmission of NDP CMAC PPDUs (e.g., NDP PS-Poll frame) by SST STAs on their selected channel(s) for the purpose of communicating a selected subchannel to the AP. The AP is not required to use a RAW for SST sounding.

In an SST report RAW, the STA transmits a report frame to the AP not earlier than the start of its assigned RAW slot, followed by the AP's response for confirmation after a SIFS.

When the AP uses a RAW for SST sounding, the RAW Type subfield is equal to sounding RAW, and the RAW Type Options subfield is equal to SST sounding RAW in the RPS element (see 9.4.2.190) transmitted by the AP. The SST sounding sequence within the SST sounding RAW comprises a series of NDP CMAC PPDUs (e.g., NDP CTS frames), each transmitted on one of the channels among those indicated by the Channel Indication field of the RAW, starting with the lowest frequency channel and continuing in sequence with the next higher frequency channel if more than one channel is indicated. The RPS element for the SST sounding RAW specifies a start time, channel(s) and RAW duration for each RAW assignment. The AP shall not transmit any NDP CMAC PPDU on a channel within an SST sounding RAW before the TxPIFS slot boundary as defined in 10.3.7. If the AP does not observe an idle medium condition within one PIFS after switching to a channel, then the AP shall not transmit an NDP, but shall wait for the duration of an NDP before switching to the next channel. This deterministic channel switching allows listening SST STAs to predict the timing of the sounding transmission for each channel. An AP may schedule multiple SST sounding RAWs to increase the probability that a sounding frame is transmitted on each SST channel. The amount of time allocated in the sounding RAW for the channel switch operations performed by the AP is implementation dependent, and is calculated at the non-AP STA by subtracting the value $N \times$ (PIFS + NDPTxTime) from the total RAW duration and dividing the result by N-1, where N is the number of channels to be sounded.

When the AP uses a RAW for SST operation and the RAW is not a sounding RAW, then the RAW Type is generic RAW and the Channel Indication Presence bit is set to 1 and the number of channels indicated in the Channel Indication in the RPS element (see 9.4.2.190) transmitted by the AP shall be one, unless there is only one STA assigned to each slot in the RAW defined by the RPS element. An AP shall not schedule any non-SST STA within a RAW that has a Channel Indication Presence bit equal to 1.

A local S1G Beacon frame is one that was transmitted by the AP with which a STA is associated.

An SST STA may select one or more SST channels from the enabled SST operating channels as indicated in the SST Operation element transmitted by the SST AP with which it is associated. The SST STA may operate on those SST channels for the beacon interval or short beacon interval following a TBTT or TSBTT if a local S1G Beacon frame with an SST element indicating that a subset of the enabled SST channel(s) are allowed for SST operation has been received by the SST STA during that interval. The STA shall not transmit frames on the indicated allowed SST channels with a bandwidth that is wider than the Maximum Transmission Width specified in the SST element. If no local S1G Beacon frame is received following a TBTT or TSBTT, then no SST STA transmission is allowed during the beacon interval or short beacon interval that begins at that TBTT or TSBTT except on the primary channel of the BSS. If an SST STA receives a local S1G Beacon frame which contains no SST element, the SST STA may transmit on the primary channel of the BSS a PPDU of width up to the BSS bandwidth indicated in the S1G Beacon frame

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

during the beacon interval or short beacon interval that immediately follows the reception of the S1G Beacon frame.

An SST STA that has selected an SST operating channel that is not the primary channel for the BSS shall operate on the selected channel as though the channel is the primary channel of the BSS, but only at the times allowed for operation on the selected channel as indicated in this subclause.

An SST STA that selected its best SST operating channel(s) may report its selection to the SST AP by sending an NDP PS-Poll frame on the primary channel of the BSS, including the selected SST channel offset in the UDI field. The transmission of any frame on an allowed subchannel by an SST STA is an implicit indication to the AP as to the subchannel selection made by the SST STA. An SST STA may queue for transmission, a QoS Null frame addressed to the AP for this purpose. To avoid ambiguity in which subchannel has been selected by the STA as its primary channel, the STA can send the frame using the minimum width channel for the band of operation on the selected primary channel.

An SST STA that has selected a subchannel for operation should operate on that subchannel during times indicated for permitted downlink and uplink operation according to the DL Activity and UL Activity fields and the Activity Start Time field in the SST element. An AP should transmit frames to the SST STA on their selected subchannels.

An SST STA shall not transmit to the AP on an SST operating channel that is not indicated as allowed by the AP in the SST element. The set of allowed SST channels indicated by the AP in the SST element is dynamic and can change every beacon interval or short beacon interval.

An SST AP shall not be away from the primary channel of the BSS for a duration of time that exceeds the value of the dot11MaxAwayDuration during a beacon interval or short beacon interval, as defined in 11.2.3.17.

10.51.3 Periodic SST operation

During aperiodic SST operation, an SST AP signals explicit permission of SST STA transmissions during each single beacon interval or short beacon interval in which SST operation is activated by transmitting the SST element. During periodic SST operation, an SST AP signals permission of SST STA transmissions over multiple beacon intervals or short beacon intervals through the transmission of the RPS element with the Channel Indication Presence bit equal to 1 and the Periodic RAW Indication bit equal to 1.

Periodic SST operation shall follow the procedure in 10.51.2 with the additional requirement that the SST AP shall transmit at least one RPS element with the Channel Indication Presence bit set to 1 and the Periodic RAW Indication bit set to 1 preceding the first beacon interval or short beacon interval during which SST operation is permitted and no SST element shall be transmitted. The periodicity, validity, and start offset of the periodic SST operation are indicated in the Periodic Operation Parameters subfield of the RAW Assignment subfield of RPS element. When the RPS element is used to indicate a periodic SST sounding schedule, the RAW Type subfield of the RPS element is set to sounding RAW and the RAW Type Options subfield of the RPS element is set to SST sounding RAW.

10.52 Sectorized beam operation

10.52.1 Introduction

The partition of the coverage area of a BSS into sectors, each containing a subset of STAs, is called sectorization. This partitioning is generally achieved by the AP transmitting or receiving through a set of antennas or a set of synthesized antenna beams to cover different sectors of the BSS. The goal of the sectorization is to reduce medium contention or interference by the reduced number of STAs within a sector.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

AP shall cover all STAs associated to it with at least one sector or an omnidirectional beam. STAs are allowed to move from one sector to another sector. The entire BSS is assumed to be covered by the omnidirectional beam or the omnidirectional antenna of the AP.

10.52.2 Sector Capabilities Exchange

After the sectorized beam-capable non-AP STA is associated with a sectorized beam-capable AP, the AP can transmit through its sectorized beam to the non-AP STA.

If dot11S1GSectorImplemented is true, a non-AP STA shall set the Sectorized Beam-Capable field in the S1G Capabilities element it transmits to 1. The sectorized beam-capable non-AP STA shall support both group sectorization and TXOP-based sectorization operations.

If dot11S1GSectorImplemented is true, an AP shall set the Sectorized Beam-Capable field in the S1G Capabilities element it transmits as follows:

— 1 if the AP supports only TXOP-based sectorization
— 2 if the AP supports only group sectorization
— 3 if the AP supports both TXOP-based sectorization and group sectorization

A STA with dot11S1GSectorImplemented equal to false shall set the Sectorized Beam-Capable field in the S1G Capabilities element to 0.

If dot11S1GSectorTrainingOperationImplemented is true, a STA shall set the Sector Training Operation Support field in the S1G Capabilities element to 1 in the Association Request frame. If dot11S1GSectorTrainingOperationImplemented is false, the STA shall set the Sector Training Operation Support field in the S1G Capabilities element to 0. If dot11S1GSectorTrainingOperationImplemented is true, dot11HTControlFieldSupported is true.

When the AP sets the Sectorized Beam-Capable field to 3 in the S1G Capabilities element it transmits then group sectorization and TXOP-based sectorization may optionally be used at the same time if

— The AP intends to apply TXOP-based sectorization during the omnidirectional beacon interval or the sectorized beacon interval to STAs with the corresponding Sector ID.
— The AP or non-AP STA, intending to apply TXOP-based sectorization during the omnidirectional beacon interval or the sectorized beacon interval, follows the rule according to which a non-AP STA is not allowed to transmit in certain beacon intervals as described in 10.52.3.

After the exchange of the S1G Capabilities element during the Association, a sectorized beam-capable AP supporting group sectorization operation shall transmit an S1G Sector Operation element with the Sectorization Type field equal to 0 to advertise the period of the current sector, omnidirectional or sectorized beam, the current sector ID, the allowable group IDs, and the duration of the current sector in the Beacon frame to start a beacon interval. A sectorized beam-capable AP supporting TXOP-based sectorization operation may transmit an S1G Sector Operation element with the Sectorization Type field set to 1 to advertise if periodic sector training is on or off, its training period, and the remaining beacon intervals to the next periodic training in the S1G Sector Operation element in a Beacon frame.

A sectorized beam-capable AP may (re)assign a specific Sector ID to a sectorized beam-capable STA after the Association. A sectorized beam-capable STA may optionally send Sector ID feedback to its associated sectorized beam-capable AP. A sectorized beam-capable STA may optionally request sector training from its associated sectorized beam-capable AP. A sectorized beam-capable AP has at least two sectors.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA that is not sectorized beam-capable may skip the S1G Sector Operation element in the Beacon frame. In a BSS where the AP does not support group sectorization, a STA, whether it is sectorized beam-capable or not, is allowed to transmit at any beacon interval.

When performing the Sectorized beam operation described in 10.52, if management frame protection is negotiated and both STAs set the Extended S1G Action Protection field in the RSNXE that they transmit to 1, the STAs shall:

— use individually addressed Protected Sectorized Group ID List and Protected Sector ID Feedback frames instead of Sectorized Group ID List and Sector ID Feedback frames, respectively and

— discard any individually addressed Sectorized Group ID List or Sector ID Feedback frame received from the peer STA, with which management frame protection is negotiated.

STAs that exchange individually addressed Protected Sectorized Group ID List or Protected Sector ID Feedback frames shall follow the rules defined in 12.6.17.

When management frame protection is not negotiated or the Extended S1G Action Protection field is 0 in the RSNXE transmitted by either STA, the STAs shall not use the Protected Sectorized Group ID List nor the Protected Sector ID Feedback frame.

10.52.3 Group sectorization operation

Group sectorization operation is based on the AP transmitting a sectorized Beacon frame. A sectorized Beacon frame is a Beacon frame transmitted through a sectorized beam, which covers a specific sector of the BSS.

A BSS that is employing a sectorization operation is called a Sectorized BSS. The sectorization scheme of operation in a BSS is signaled by the presence of an S1G Sector Operation element in Beacon frames, Probe Response frames, and Association Response frames.

In a Sectorized BSS, the AP may alternate the sectorized beacons and the nonsectorized (omnidirectional) beacons, as illustrated by the example in Figure 10-145 (Sectorized BSS operation). More than one sector could be active at the same time, i.e., they can overlap in time. In such case, STAs from different sectors are allowed to transmit while their sectors are active. During the omnidirectional beacon interval all the STAs in the BSS may transmit regardless of their geographical locations. Sectorized beacons are transmitted to selected geographical areas to inform groups of STAs that they are allowed to transmit during the sector intervals specified in the S1G Sector Operation element. The AP with group sectorization operation receives transmissions from all sectors continuously.

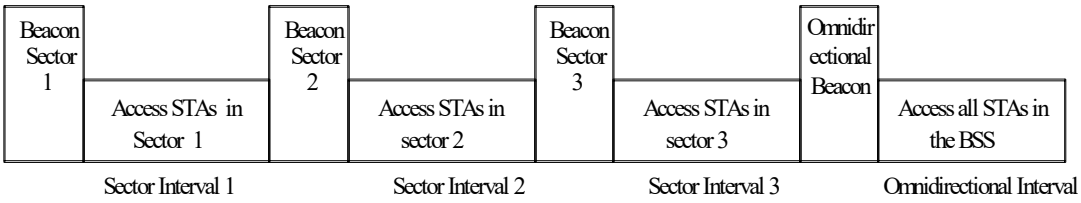

Figure 10-145—Sectorized BSS operation

All beacons in a sectorized BSS carry the S1G Sector Operation element. The 1-bit Omni field indicator within the S1G Sector Operation element distinguishes between the sectorized Beacon frame and the omnidirectional Beacon frame transmission. The S1G Sector Operation element further specifies the type of sectorization operation, the type of Beacon frame (sectorized or omnidirectional), the complete rotation period of all (sectorized and omnidirectional) beacons, the subperiod for the current Beacon frame, and the list of groups of STAs that are allowed to transmit during the current beacon interval.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In a Sectorized BSS with group sectorization operation, each STA is allocated a group ID related to the sectorization operation. STAs that have group ID zero are allowed to transmit in all beacon intervals. A STA that is sectorized beam capable and whose group ID is contained in the list of group IDs carried in the S1G Sector Operation element in a Beacon frame is allowed to transmit until the next TBTT. By default all STAs have group ID 0 unless otherwise specified at the association. Because by default all STAs that support group sectorization belong to group ID 0 before association, all the STAs can transmit at any time before their association. It is expected that during the association, STAs receive a nonzero group ID, which restricts their activity to a particular sector interval and omnidirectional time interval. The AP may allow some STAs to have the group zero even after association, for instance public safety STAs or some high priority sensors.

A STA that receives a Beacon frame in a Sectorized BSS shall verify if its group ID is contained in the group ID list of the S1G Sector Operation element in the Beacon frame if it intends to transmit before the next TBTT. A STA that has a nonzero group ID, which is not listed in the S1G Sector Operation element of the Beacon frame, is not allowed to transmit during that sector duration.

The STAs that do not support the group sectorization operation are not subject to the rules defined in this subclause.

In a Group Sectorized BSS,

— The S1G AP shall transmit omnidirectional Beacon frames every dot11BeaconPeriod as described in 11.1.2.1.

— The S1G AP may transmit sectorized Beacon frames every sectorized beacon interval. A non-AP STA that is associated to the AP and is group sectorized capable shall transition to awake state to read the sectorized Beacon frame if it intends to access the medium during the sectorized beacon interval. A non-AP STA that is not group sectorized capable may discard the sectorized Beacon frame and is not subject to the rules described in this subclause.

The purpose of group sectorization operation is to allow the channel access of one or multiple groups of STAs at the time, where the STA group allocation is based on STA sector location and other grouping criteria (e.g., the device type, or traffic type, or the received SNR) in order to reduce the number of hidden nodes that simultaneously access the AP.

Two or more sectors may be active at the same time, i.e., their active time can overlap. In this case the STAs are allowed to transmit in more than one sector. Figure 10-145 (Sectorized BSS operation) presents an example of three nonoverlapping sectors followed by an omnidirectional period. Each sector starts with sectorized Beacon frame that provides the sector ID and the duration of sector activity.

10.52.4 TXOP-based sectorization operation

TXOP-based sectorization operation is based on an AP transmitting or receiving through the sectorized beam within a TXOP. At the beginning of a frame exchange sequence, the AP may start with the omnidirectional beam transmission to establish a link with a STA and to set up protection duration within a TXOP before switching to the sectorized beam transmission and reception. In different TXOPs, the AP may use different sectorized beams to communicate with different STAs. A Sectorized beam capable AP supporting TXOP-based sectorization operation shall support transmitting or receiving through both the omnidirectional beam or the sectorized beams.

In a BSS with TXOP-based sectorization operation, the AP shall signal the operation in Beacon frames, Probe Response frames, Association Response frames, or other frames using the S1G Sector Operation element. The operation of TXOP-based sectorization is defined by the following rules:

— The switching from an omnidirectional beam transmission to a sectorized beam transmission occurs when the bit position corresponding to the sector is 1 in the TXVECTOR parameter SECTOR_ID.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— When an AP is aware of the sector in which a STA is in, AP may select the sectorized beam by setting the bit position corresponding to the sector to 1 in the TXVECTOR parameter SECTOR_ID when it transmits to or receives from the STA. Otherwise, the AP transmits or receives through the omnidirectional beam to the STA.
— Once AP transmits to a STA through a sectorized beam by setting the bit in the TXVECTOR parameter SECTOR_ID that corresponds to that sector to 1, it shall use the same sectorized beam to receive from the STA within the same TXOP.
— Once the AP switches to the sectorized beam transmission during an exchange, it shall continue with sectorized beam transmission using the same sectorized beam and the TXOP truncation is not allowed for the remaining duration of the NAV/RID protection.
— An AP shall use the same sectorized beam for transmission after a PIFS recovery or backoff recovery in a TXOP.
— TXOP sharing for relaying shall not be used in a TXOP.

Note that a possible realization of an omnidirectional beam is by setting bit positions of all available sectors to 0. Another possible realization of omnidirectional beam is by setting all bit positions to 1 in the TXVECTOR parameter SECTOR_ID and the CSD are inserted to different sectorized beams to avoid unintentional beamforming.

In TXOP-based sectorization operation, during a frame exchange between the AP employing sectorized beamforming and a non-AP STA, spatial reuse by OBSS APs or OBSS non-AP STAs sharing the same wireless medium is allowed under the following rules:

When a protection NAV and RID for a TXOP is set up by an AP's omnidirectional beam transmission and a spatially orthogonal (SO) condition is confirmed by an OBSS non-AP STA or OBSS AP, the OBSS non-AP STA or OBSS AP may initiate an SO exchange after an SO-Backoff. For a non-AP STA the SO-Backoff is initialized with the AC_VO parameters from the most recently received EDCA Parameter Set element sent by the AP with which the STA is associated. For an AP the SO-Backoff is initialized with the AC_VO parameters of the AP. The SO-Backoff function begins or resumes when the SO condition is confirmed. The SO-Backoff function is independent of all other backoff functions but follows the EDCAF backoff procedure as defined in 10.2.3. An OBSS non-AP STA or OBSS AP that invokes or resumes an SO-Backoff at the confirmation of an SO condition shall set an SO timer to MAX(NAV, RID) and reset its NAV and RID and suspend EDCAF backoff procedures. At the expiry of the SO timer, the SO-Backoff is suspended and the suspended EDCAF backoff procedures resume. An OBSS non-AP STA or OBSS AP that initiates a new spatially orthogonal frame exchange sequence after an SO-Backoff procedure shall start the exchange with a nonbeamformed RTS/CTS and shall limit the duration of the exchange such that it ends before the expiry of the SO timer. The new frame exchange sequence as described is called a spatially orthogonal frame exchange sequence. The new spatially orthogonal frame exchange sequence initiator may transmit frames from any AC. The STA shall obey the TXOP limit of the AC of the frames transmitted within the SO frame exchange sequence. A STA that transmits an SO frame exchange sequence may transmit additional SO frame exchange sequences by continuing to use the SO-Backoff function until the expiry of the SO timer. If the ongoing frame exchange sequence transmission is between a pair of STAs within its BSS, the STA does not reset its NAV and its RID even though the spatially orthogonal conditions are met. Within the new spatially orthogonal exchange, an OBSS AP shall use an antenna setting which is same as the antenna setting used to detect the SO condition for transmission.

The SO condition is satisfied if an OBSS non-AP STA or OBSS AP which receives the omnidirectional transmission but not the subsequent sectorized beam transmission from the AP and not the transmission from the STA involving in the frame exchange sequence.

Four types of frame exchange sequences, which can lead to the SO conditions by OBSS non-AP STAs or OBSS APs are described.

a) SO frame exchange sequence 1: As illustrated in Figure 10-146 (SO frame exchange sequence 1), the AP starts a frame exchange sequence with the omnidirectional beam to establish a link with a STA and set up the protection for the duration of the sectorized beam transmission. The second PPDU has a long format, AP switches to the sectorized beam transmission after the omnidirectional preamble of the long preamble. The AP continues with the sectorized beam transmission for the remaining duration of the NAV/RID protection. An OBSS non-AP STA or OBSS AP receives the omnidirectional beam transmission from the AP may attempt to start an SO frame exchange sequence by detecting an SO condition. An SO condition is confirmed by an OBSS non-AP STA or OBSS AP, which observes the omnidirectional transmission of the AP but not the beamformed preamble of the AP and not the STA's transmission.

   Note that an OBSS non-AP STA or OBSS AP infers its spatial orthogonality by

   1) Observing the first omnidirectional beam PPDU and the omnidirectional preamble of the long preamble from the AP.
   2) Not observing the subsequent sectorized beam transmission from the AP for the duration of one symbol (D-STF as shown in Figure 23-2 (S1G_LONG format)) following the omnidirectional portion of the S1G_LONG format.
   3) Observing a gap of no transmission between the first omnidirectional beam PPDU and the omnidirectional preamble of the long preamble by the AP.

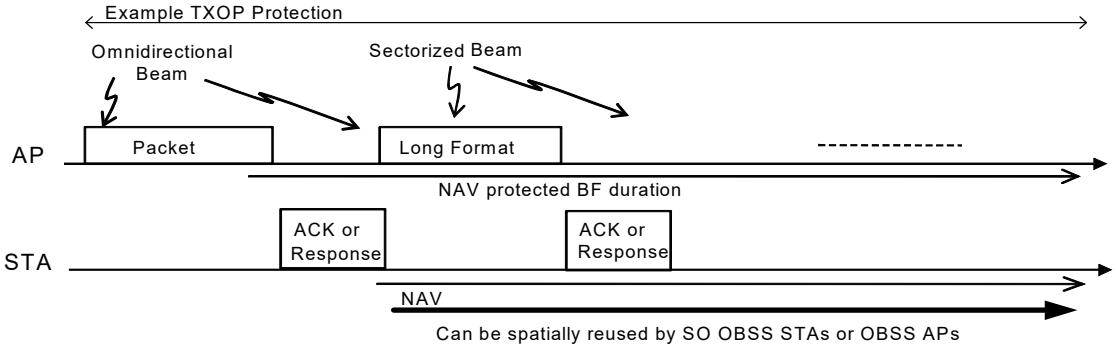

Figure 10-146—SO frame exchange sequence 1

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

b) SO frame exchange sequence 2: As illustrated in Figure 10-147 (SO frame exchange sequence 2), the AP starts a frame exchange sequence with the omnidirectional transmission of a PPDU to establish a link with a STA and to set up the protection for the duration of the sectorized beam transmission. Subsequently, the AP switches to a sectorized beam transmission for the remaining duration of the NAV/RID protection. An OBSS non-AP STA or OBSS AP receives the omnidirectional beam transmission from the AP may attempt to start an SO frame exchange sequence by detecting the SO condition. SO condition is confirmed by an OBSS non-AP STA or OBSS AP, which observes the omnidirectional transmission of the AP but not the beamformed transmission of the AP and not the STA's transmission.

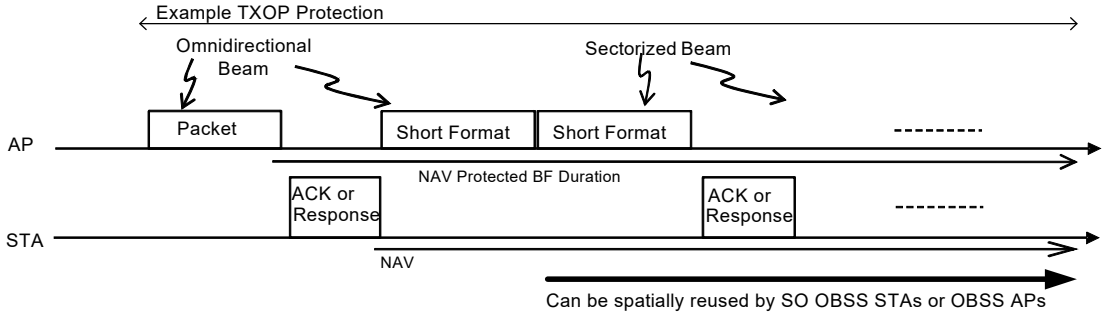

Figure 10-147—SO frame exchange sequence 2

Note that an OBSS non-AP STA or OBSS AP infers its spatial orthogonality by

1) Observing the omnidirectional beam transmission by the AP.
2) Not observing the subsequent sectorized beam transmission by the AP for aSIFSTime + aSlotTime + aRxPHYStartDelay duration.
3) Observing a gap of no transmission between the first two omnidirectional beam PPDUs by the AP.

c) SO frame exchange sequence 3: The AP starts a frame exchange sequence with an omnidirectional RTS frame to solicit a CTS response from a STA and uses the omnidirectional transmission to set up the protection for the duration of the sectorized beam transmission and then switches to the sectorized beam transmission for the remaining duration of the NAV/RID protection. SO condition is confirmed by an OBSS non-AP STA or OBSS AP, which observes the omnidirectional transmission of the AP but not the beamformed transmission of the AP and not the STA's transmission. Note that in the first diagram in Figure 10-148 (SO frame exchange sequence 3), an OBSS non-AP STA or OBSS AP infers its spatial orthogonality with the AP by observing the omnidirectional beam RTS frame and the omnidirectional portion of the long format for the duration of one symbol (D-STF as shown in Figure 23-2 (S1G_LONG format)) following the omnidirectional portion of the S1G_LONG format but not the subsequent sectorized beam transmission and with the STA by observing a gap of no transmission between the omnidirectional RTS frame and the omnidirectional preamble of the long preamble. Note that in the second diagram in Figure 10-148 (SO frame exchange sequence 3), an OBSS non-AP STA or OBSS AP infers its spatial orthogonality with the AP by observing the transmission of the omnidirectional beam RTS frame and the omnidirectional beam PPDU of the short format but not observing the subsequent sectorized beam transmission for aSIFSTime + aSlotTime + aRxPHYStartDelay duration and with the STA by observing a gap of no transmission between the omnidirectional RTS frame and the omnidirectional beam PPDU of the short format by the AP.

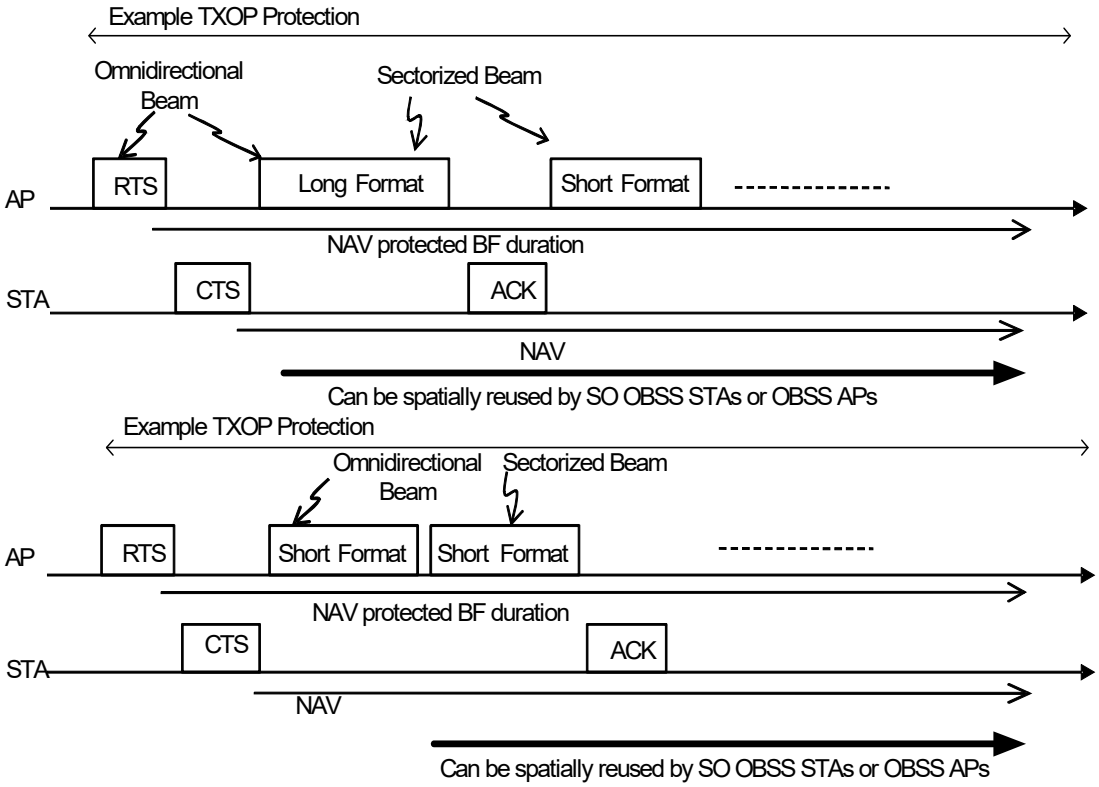

Figure 10-148—SO frame exchange sequence 3

d) SO frame exchange sequence 4: A STA starts with the omnidirectional beam to establish a link with the AP. AP uses omnidirectional transmission as the responding and to set up the protection for the duration of the remaining TXOP. Then the AP transmits the sectorized beam transmission (either an omnidirectional preamble of a long preamble or an omnidirectional transmission of a subsequent PPDU) and switches to the sectorized beam transmission. The AP continues with the sectorized beam transmission for the remaining duration of the NAV/RID protection. SO condition is confirmed by an OBSS non-AP STA or OBSS AP, which observes the omnidirectional transmission of the AP but not the beamformed transmission of the AP and not the STA's transmission.

   Note that in the first diagram in Figure 10-149 (SO frame exchange sequence 4), an OBSS non-AP STA or OBSS AP infers its spatial orthogonality with the AP by observing the omnidirectional beam frame and the omnidirectional portion of the long format for the duration of one symbol (D-STF) following the omnidirectional portion of the S1G_LONG format but not the subsequent sectorized beam transmission and with the STA by observing a gap of no transmission before the AP response to PS-Poll frame or trigger frame from the STA. Note that in the second diagram in Figure 10-149 (SO frame exchange sequence 4), an OBSS non-AP STA or OBSS AP infers its spatial orthogonality by

   1) Observing the omnidirectional beam PPDU of the short format from the AP.
   2) Not observing the subsequent sectorized beam transmission by the AP for aSIFSTime + aSlotTime + aRxPHYStartDelay duration.
   3) Observing a gap of no transmission before the first omnidirectional beam PPDU of the short format by the AP.

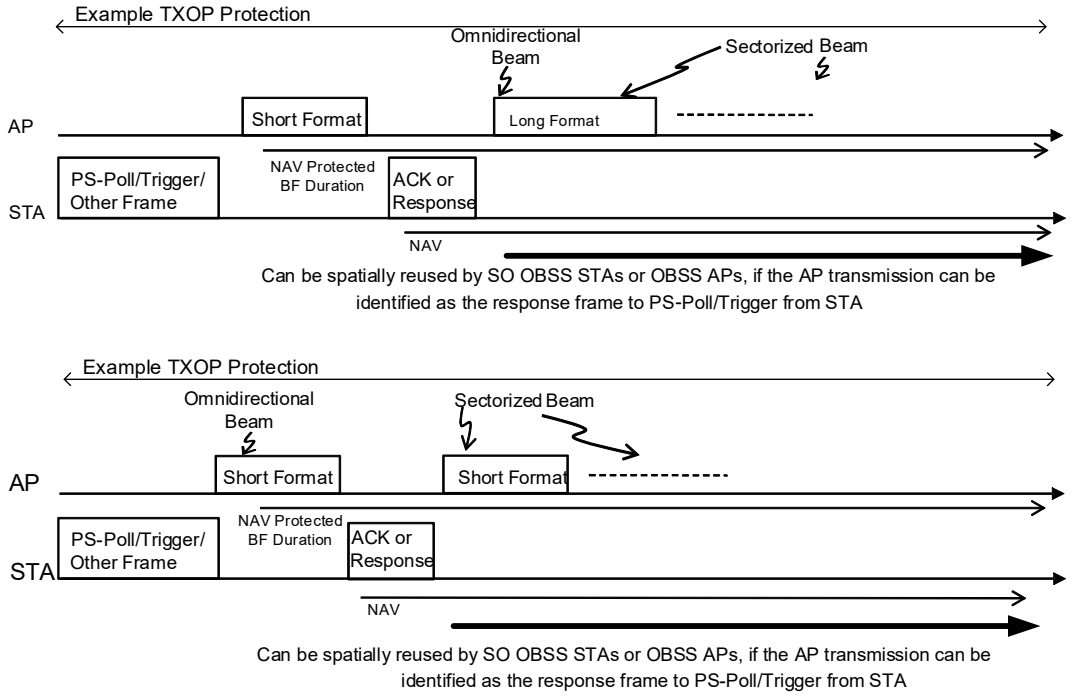

Figure 10-149—SO frame exchange sequence 4

To facilitate the detection of the spatially orthogonal conditions by OBSS non-AP STAs or OBSS APs, the NDP CTS frame may be transmitted preceding the SO frame exchange sequence. If the Early Sector Indicator in the NDP CTS frame is equal to 1, it indicates that the NDP CTS frame is followed by the sectorized beam frame exchange sequence. Setting the Early Sector Indicator to 1 and Address Indicator to 0 also indicates to the OBSS STAs that it might cancel its NAV and its RID setting if the spatially orthogonal conditions are subsequently met. If the ongoing frame exchange sequence transmission preceding the NDP CTS frame is between a pair of STAs within its BSS, the STA does not reset its NAV and its RID even though the spatially orthogonal conditions are met. The RXVECTOR parameter COLOR is utilized to detect the SO condition by classifying the received PPDU between a same BSS transmission and an OBSS transmission. Hence, if the Early Sector Indicator is equal to 0, OBSS STA need not check for spatially orthogonal conditions. Figure 10-150 (CTS-to-self preceding SO frame exchange sequence) illustrates the frame exchange sequence preceded by CTS-to-self using NDP CTS frame.

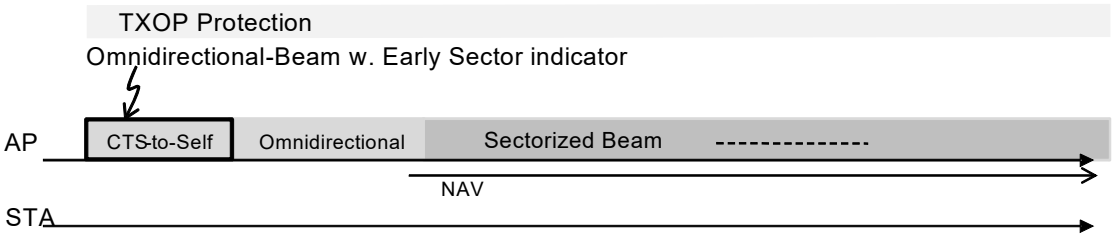

Figure 10-150—CTS-to-self preceding SO frame exchange sequence

10.52.5 Sector training operation

10.52.5.1 Introduction

Sector training is one way to help the STAs to determine the best sectors to communicate with the AP. In sector training, an AP with dot11S1GSectorTrainingOperationImplemented equal to true shall transmit training NDP CTSs over all sectors. The best sector might be chosen by a STA based on instantaneous or averaged CSI. The specific method of choosing the sector is beyond the scope of this standard. The results of sector training may be fed-back by the STAs to the AP using Sector ID feedback frame. These training NDP CTSs (with the Address Indication bit set to 1 and the RA/Partial BSSID field set to the partial BSSID of the AP's BSS) shall be transmitted consecutively and should be sent within a single TXOP. Sector training is set up or requested using the HT variant Control field. Sector training supports up to eight sectors. The AP may use other methods to determine the STA's best sector.

10.52.5.2 Procedure

In sector training, the AP sends a sector training announcement followed by a series of NDP CTS sector training frames separated by SIFS.

In TXOP-based sectorization operation, sector training may occur periodically with the training period and the beacon interval in which the training occurs as indicated in S1G Sector Operation element (TXOP-based), in response to a request from a STA, or initiated by the AP. The STAs may perform sector training by receiving the training NDP CTSs from AP. When the AP receives the sector training request from a STA, the AP shall schedule sector training. AP supporting TXOP-based sectorization shall support sector training and sector training request. In the S1G Sector Operation element (TXOP-based) (see 9.4.2.194), which is transmitted in Beacon frame, Probe Response frame, or Association Response frame, the AP indicates in which beacon interval sector training occurs.

In group sectorization operation, a STA can find its best sector ID by listening to all the sectorized beacons transmitted during dot11BeaconPeriod. The S1G Sector Operation element (group) carried in the sectorized Beacon frame provides the sectorized beacons' rotation period, current sector ID, the subperiod of the current sector and the group IDs of the groups of STAs that are allowed to transmit within the current beacon interval. Sector training may also be used by STAs to reduce time for sector discovery, and to achieve power saving by not having to listen to all the sectorized beacons.

The STA may use the Sector ID feedback frame (see 9.6.24.11) to indicate to the AP which sector is selected.

The STA may request sector training from AP by using the HT variant Control field if it is capable of sector training request. By setting the MAI=14 in the Link Adaptation Control subfield of the HT variant Control field, the STA indicates HT variant control field is used for sector training (or antenna selection) information. Sector training (or sector training resumption) is requested by a STA when the ASELC subfield is equal to 1 and the ASEL Data subfield with values in the range 1 to 15, being the number of the first NDP CTS training frames to be transmitted when the command is sector training resumption, where 0 corresponds to the first training frame in the sector training request. When the HT NDP Announcement subfield is also equal to 1, it indicates training NDP CTS frames to follow with consecutive training NDP CTS frames separated by SIFS.

The frame exchange sequence for sector training is shown in Figure 10-151 (Sector training), where the AP transmits training NDP CTS frames, and the STA provides Sector ID feedback. The frame exchange sequence comprises the following steps:

a) (Optional) A STA may initiate sector training by sending a +HTC frame with the ASELC set to 1 for sector training request.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

b) The AP sends out consecutive training NDP CTSs (with the Address Indication bit set to 1 and the RA/Partial BSSID field set to the partial BSSID of the AP's BSS) separated by SIFS in a TXOP of which it is the TXOP holder with no Ack over different sectorized beams. NDP CTS frames (23.3.12.2.1), with NDP CMAC PPDU Type=0, are used in sector training. Each training NDP CTS frame is transmitted over one sector beam. The first training NDP CTS frame shall be preceded by a +HTC frame with HT NDP Announcement subfield set to 1. The positions of the training NDP CTS frames correspond to the sector IDs of the sectorized beams, in ascending order starting with Sector ID =0.

c) The STA(s) may perform training by selecting the antenna sector based on NDP CTS training frames.

d) The STA(s) engages in the training by receiving the sector training frames may respond with a selected sector ID using the sector ID feedback frame in a subsequent TXOP or during sector report RAW, which may be indicated by Beacon frame for fast sector discovery of multiple STAs (see 10.52.5.4),

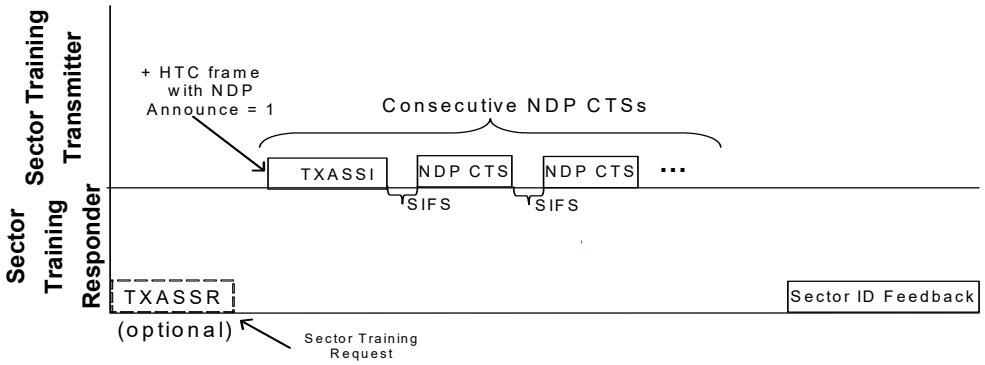

Figure 10-151—Sector training

If the AP receives a +HTC MPDU with the MAI subfield equal to 14, the ASEL Command subfield equal to sector training request (i.e., the field value is 1), and the ASEL Data subfield equal to zero to correspond to the command sector training, the STA shall assume a total number of training NDP CTSs that corresponds to the total number of sectors. If the AP receives a +HTC MPDU with the MAI subfield equal to 14, the ASEL Command subfield equal to sector training request (i.e., the field value is 1), and the ASEL Data subfield equal nonzero value to correspond to the command sector training resumption (a resumption MPDU), the STA shall assume the number of training frames that follow the resumption MPDU is equal to the number of training NDP CTSs from the total number of sectors minus the order number transmitted in the ASEL Data subfield of the Resumption MPDU.

An AP may schedule sector sounding for multiple STAs by RAW in a beacon interval using the RAW Parameter Set element with the RAW Type field equal to sounding RAW and the RAW Type Options subfield equal to sector sounding RAW (see 9.4.2.190). During the sounding RAW, non-AP STAs that are associated with the AP are expected not to access the WM during the RAW duration as described in 10.23.5 and can elect to listen to the training NDP CTS frames transmitted by the AP. This sector sounding RAW may be scheduled as periodic or nonperiodic.

Sector training within the sector sounding RAW starts with a frame with HT NDP Announcement subfield equal to 1 in the HT control field and is followed in SIFS by a number of NDP CTS frames, each transmitted through different antenna sector starting with Sector ID equal to 0, and separated by SIFS. If the RAW Type and the RAW Type Options subfield do not indicate that the RAW is a sector sounding RAW, no sector sounding is performed within the RAW.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Channel bandwidth for sector training shall be a width up to the BSS bandwidth indicated in the S1G Beacon frame during the beacon interval. The AP may transmit NDP CTS frames for sector sounding in parallel (e.g., with a value of S1G_DUP_2M for the TXVECTOR parameter FORMAT and a value of CBW8 for the TXVECTOR parameter CH_BANDWIDTH in a BSS with an operating width of 8 MHz). The Bandwidth Indication field in the sounding frames (in NDP_2M CTS frame) and the Channel Indication field in the sounding RAW shall comply with the TXVECTOR parameter CH_BANDWIDTH.

10.52.5.3 Sector ID feedback

A STA may optionally use an Unprotected S1G Action frame (see 9.6.24.11) for (solicited and unsolicited) Sector ID feedback.

10.52.5.4 Fast Sector Discovery

When multiple STAs report their sector IDs using the Sector ID feedback frames to AP, Sector ID feedback frames may be protected by sector report RAW(s) (see 9.4.2.190) indicated in the Beacon frame to avoid contentions with others. The sector report RAW(s) may be assigned after the sector sounding RAW for fast sector discovery of multiple STAs.

In the sector report RAW, the STA transmits a report frame to the AP not earlier than the start of its assigned RAW slot, followed by the AP's response for confirmation after a SIFS.

10.53 S1G relay operation

10.53.1 General

An S1G relay consists of an S1G relay AP, an S1G relay STA and a relay function.

NOTE—An S1G relay AP is not an S1G relay STA, though it is an S1G STA.

An S1G relay consists of an AP with dot11RelayAPImplemented equal to true and a STA with dot11RelaySTAImplemented equal to true.

An example of a relay function is illustrated in Figure 10-152 (S1G relay architecture), where Relay 1, Relay 2, and Relay 3 are S1G relays, each of which consisting of an S1G relay STA, an S1G relay AP and a relay function. The S1G relay STAs of Relay 1 and Relay 2 are associated with an AP that is an S1G root AP. The S1G relay STA of Relay 3 is associated with the S1G relay AP of Relay 1. STA 1 is a non-AP STA associated with the S1G relay AP of Relay 1. STA 2, and STA 3 are non-AP STAs associated with the S1G relay AP of Relay 3. STA 4 and STA 5 are non-AP STAs associated with the S1G relay AP of Relay 2. Frames from STA 1 are forwarded via the relay function of Relay 1 from the S1G relay AP to the S1G relay STA and then to the S1G root AP. Similarly, frames from the S1G root AP are forwarded to STA 1 via the S1G relay STA, the relay function and the S1G relay AP of Relay 1. Similar forwarding is done by Relay 3 and Relay 1 in sequence to handle frames from STA 2 and STA 3 relaying multiple times to or from the root AP.

Relay STA in this context refers to a non-AP STA.

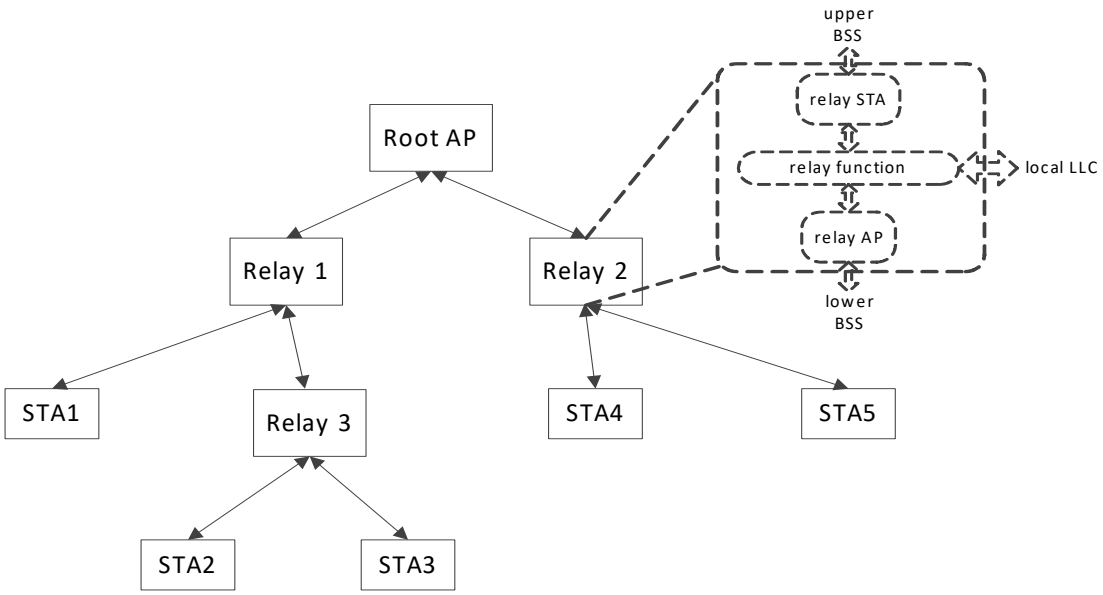

Figure 10-152—S1G relay architecture

10.53.2 S1G relay operation

A non-AP STA with dot11RelaySTAImplemented equal to true shall include the S1G Relay Activation element in (Re)Association Request frames.

A non-AP STA with dot11RelaySTAImplemented equal to true may include an S1G Relay Activation element with Relay Activation Mode subfield equal to 1 in (Re)Association Request frames, Relay Activation Request frames or Relay Activation Response frames. A non-AP STA with dot11RelaySTAImplemented equal to true may transmit a Relay Activation Request frame to the AP with which it is associated.

A non-AP STA shall not transmit an S1G Relay Activation element that has the Enable Relay Function and the Relay Activation Mode subfields equal to 1 if the most recently received S1G Relay element from the AP to which it is associated had the No More Relay Flag subfield equal to 1.

A non-AP STA with dot11RelaySTAImplemented equal to false shall not include the S1G Relay Activation element in any frames that it transmits.

A non-AP STA transmitting an S1G Relay Activation element shall set the Direction subfield of the element to 0. An AP transmitting S1G Relay Activation element shall set the Direction subfield of the element to 1.

An AP that is the intended receiver of a frame that contains an S1G Relay Activation element with Relay Activation Mode subfield equal to 1 shall respond with the appropriate frame (Probe, (Re)Association, Relay Activation Response) that contains an S1G Relay Activation element with Relay Activation Mode subfield equal to 0.

A non-AP STA with dot11RelaySTAImplemented equal to true shall transmit a Relay Activation Response frame if it receives the corresponding S1G Relay Activation element in a Relay Activation Request frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A non-AP STA with dot11RelaySTAImplemented equal to true that is the intended receiver of a frame that contains an S1G Relay Activation element with Relay Activation Mode subfield equal to 1 and Enable Relay Function subfield equal to 0 shall respond with a frame that contains an S1G Relay Activation element with Relay Activation Mode and Enable Relay Function subfields equal to 0.

An AP may indicate the maximum number of STAs, N_{max}, that an S1G relay is allowed to associate by including a Number of STAs field in an S1G Relay Activation element with the Enable Relay Function subfield equal to 1 transmitted to the S1G relay.

A non-AP STA with dot11RelaySTAImplemented equal to true shall set dot11RelaySTAOperationActivated to false unless

a) It receives an S1G Relay Activation element from the AP to which it is associated with Enable Relay Function subfield equal to 1 and Relay Activation Mode subfield equal to 0 as a response of a transmitted S1G Relay Activation element with Enable Relay Function and Relay Activation Mode subfield equal to 1.
b) It transmits an S1G Relay Activation element to the AP to which it is associated with Enable Relay Function subfield equal to 1 and Relay Activation Mode subfield equal to 0 as a response of a received S1G Relay Activation element with Enable Relay Function and Relay Activation Mode subfield equal to 1.

If event a) or b) occurs, then it shall set dot11RelaySTAOperationActivated to true.

A non-AP STA with dot11RelaySTAOperationActivated equal to true is referred to as an S1G relay STA.

An AP with dot11RelayAPImplemented equal to true may include an S1G Relay Activation element with Relay Activation Mode subfield equal to 0 in (Re)Association Response frames, Probe Response frames, Relay Activation Request frames or Relay Activation Response frames.

An AP with dot11RelayAPImplemented equal to true (e.g., the AP in an S1G relay) shall set dot11RelayAPOperationActivated to true only if dot11RelaySTAOperationActivated of the non-AP STA in the relay is true, otherwise it shall set dot11RelayAPOperationActivated to false.

An AP with dot11RelayAPOperationActivated equal to true is referred to as an S1G relay AP.

An S1G relay AP shall include an S1G Relay element in transmitted Beacon frames, PV1 Probe Response frames and Probe Response frames.

An S1G relay AP shall set the No More Relay Flag subfield of an S1G Relay element to 1 if the No More Relay Flag subfield of the latest S1G Relay element received from its parent AP was set to 1. An S1G relay AP may set the No More Relay Flag subfield of the S1G Relay element to 1 in order to limit the number of Relays in its associated STAs.

An S1G Relay AP shall reject association requests when N_{max} has been reached, citing status code 17 (DENIED_NO_MORE_STAS).

An AP with dot11RelayAPImplemented equal to true shall include the S1G Relay element in its Beacon frames and may include the S1G Relay element in its Probe Response frames, PV1 Probe Response frames, and (Re)Association Response frames.

An S1G root AP is defined as an AP with dot11RelayAPImplemented equal to true that sets the Hierarchy Identifier field of transmitted S1G Relay elements to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An S1G relay AP shall not set the Hierarchy Identifier field of transmitted S1G Relay elements to 0.

An S1G relay AP shall use the same SSID as the AP to which its S1G relay STA is associated.

An S1G relay STA shall send a Reachable Address element that contains the current list of reachable addresses, in the (Re)Association Request frame to the AP to which it is associating. In this frame the relay STA shall set the Initiator MAC address field of the element to its own MAC address, and the Add/Remove subfield to 1.

An S1G relay STA shall send a Reachable Address Update frame to the AP to which it is associated when one of the following conditions occurs:

1) A new non-AP STA associates with the S1G relay AP of the relay.
2) A non-AP STA is disassociated or deauthenticated from the S1G relay AP of the S1G relay.
3) A Reachable Address Update frame is received at the S1G relay AP of the S1G relay.

For conditions 1 and 2 above, the transmitted Reachable Address Update frame shall include Reachable Address subfields for STAs with a changed association or authentication status.

For condition 3 above, the transmitted Reachable Address Update frame shall include all Reachable Address subfields from the received Reachable Address Update frame,

a) Where the received Reachable Address subfield had the Add/Remove subfield equal to 1 (STA joining the relay).
b) Where the received Reachable Address subfield had the Add/Remove subfield equal to 0 (STA leaving the relay), except when the received Reachable Address Update frame came from a Relay STA that is not the next hop for the indicated STA.

The Reachable Address Update frame shall not contain Reachable Address subfields other than those defined for conditions 1) to 3) above. Because the generation of a Reachable Address Update frame might not be immediate, Reachable Address subfields which have different initiator MAC addresses may be combined in a single Reachable Address Update frame under the above conditions.

Reachable Address subfields with the Add/Remove subfield equal to 0 (STA leaving the relay) shall be ignored when received from an S1G relay STA that is not the S1G relay STA that transmitted the most recently received Reachable Address Update frame containing a Reachable Address subfield for the indicated STA with the Add/Remove subfield equal to 1 (STA joining the relay).

An S1G relay STA generating a Reachable Address frame [under conditions 1) and 2) above] shall set the Initiator MAC address field of the element to its own MAC address.

An S1G relay STA shall set the Add/Remove subfield of a Reachable Address Update frame to 1 if the STA identified by the MAC Address subfield of Reachable Address subfield is associated to the relay AP of the S1G relay and shall set the Add/Remove subfield to 0 if the STA identified by the MAC Address subfield of Reachable Address subfield disassociated from the S1G relay AP of the S1G relay.

An S1G relay STA shall set the Relay Capable subfield of the Reachable Address subfield of the Reachable Address element to 1 only if the STA identified by the MAC address subfield of the Reachable Address subfield has indicated that it is capable of relay function, otherwise, it shall set it to 0.

An S1G root AP shall update the DS upon receipt of a Reachable Address Update frame.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

10.53.3 Addressing and forwarding of individually addressed relay frames

A MAC service tuple (including an MSDU) received via the WM at an S1G relay AP is examined by the relay function, and if the DA matches the address of the STA of the S1G relay the MAC service tuple is delivered via the MAC service to the local higher layer entity. Otherwise, the MAC service tuple is passed to the S1G relay STA and then is forwarded via the WM to the AP to which it is associated, using either a four-address frame format or an A-MSDU format except when the frame carrying the (A-)MSDUs is a PV1 QoS Data frame for which header compression is used as described in 10.57.

The addressing of the four-address frame shall be as follows in this case:

- Address 1 is the MAC address of the AP (the receiver of the MPDU)
- Address 2 is either the MAC address or the AID of the S1G relay STA (the transmitter of the MPDU)
- Address 3 is the DA of the MSDU (the destination address of the MSDU)
- Address 4 is the SA of the MSDU (the source address of the MSDU)

If the four-address frame is a PV1 QoS Data frame that contains an A-MSDU then the DA and/or SA field(s) shall not be present in any of the A-MSDU subframe headers unless the DA and/or SA for the MSDU contained in the A-MSDU subframe are not equal to the values contained in Address 3 and/or Address 4 of the frame.

Otherwise, the addressing of the frame containing an A-MSDU shall be as follows in this case:

- Address 1 is the MAC address of the AP (the receiver of the MPDU)
- Address 2 is either the MAC address or the AID of the S1G relay STA (the transmitter of the MPDU)
- Address 3 is the MAC address of the AP (the BSSID)
  - If the frame is a PV1 QoS Data frame then Address 3 is not present
- DA in A-MSDU subframe header is the DA of the MSDU (the destination address of the MSDU)
- SA in A-MSDU subframe header is the SA of the MSDU (the source address of the MSDU)

A MAC service tuple passed to a root AP from the DS, or received at an S1G relay STA via the WM, is examined by the relay function, and if the DA matches the address of the AP or an associated non-AP STA, it is delivered using legacy (non-relay) methods. Otherwise, the included MSDU is forwarded via the WM to the associated S1G relay STA that most recently included the MSDU's DA in a Reachable Address element, using either a four-address frame format or an A-MSDU format.

The addressing of a four-address frame shall be as follows in this case:

- Address 1 is either the MAC address or the AID of the S1G relay STA (the receiver of the MPDU)
- Address 2 is the MAC address of the AP (the transmitter of the MPDU)
- Address 3 is the DA of the MSDU (the destination address of the MSDU)
- Address 4 is the SA of the MSDU (the source address of the MSDU)

If the four-address frame is a PV1 QoS Data frame that contains an A-MSDU then the DA and/or SA field(s) shall not be present in any of the A-MSDU subframe headers except when DA and/or SA for the MSDU contained in the A-MSDU subframe are different from the values contained in Address 3 and/or Address 4 of the frame.

Otherwise, the addressing of a frame containing an A-MSDU shall be as follows in this case:

- Address 1 is either the MAC address or the AID of the S1G relay STA (the receiver of the MPDU)
- Address 2 is the MAC address of the AP (the transmitter of the MPDU)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

- Address 3 is the MAC address of the AP (the BSSID)
  - If the frame is a PV1 QoS Data frame then Address 3 is not present
- DA in A-MSDU subframe header is the DA of the MSDU (the destination address of the MSDU)
- SA in A-MSDU subframe header is the SA of the MSDU (the source address of the MSDU)

When the frame is a PV1 QoS Data frame and the intended receiver has confirmed storing A3 and/or A4 as described in 10.57 then the DA and/or SA should not be present in either the A3 and/or A4 fields of the frame or in the DA and/of SA of the A-MSDU subframe header contained in the frame except when the DA and/or SA for the MSDU are different from the stored values.

10.53.4 Addressing and forwarding of group addressed relay frames

A MAC service tuple with a destination address that is a group address (including an MSDU) received via the WM at an S1G relay AP is passed by the relay function to the S1G relay STA and then is forwarded via the WM to the AP to which the S1G relay STA is associated, using either a four-address frame format or an A-MSDU format except when the frame carrying the (A-)MSDUs is a PV1 QoS Data frame for which header compression is used as described in 10.57.

The addressing of the four-address frame shall be as follows in this case:

- Address 1 is the MAC address of its associated AP (the receiver of the MPDU)
- Address 2 is either the MAC address or the AID of the S1G relay STA (the transmitter of the MPDU)
- Address 3 is the DA of the MSDU (the group address).
- Address 4 is the SA of the MSDU (the source address of the group addressed MSDU)

If the four-address frame is a PV1 QoS Data frame that contains an A-MSDU then the DA and/or SA field(s) shall not be present in any of the A-MSDU subframe headers unless the DA and/or SA for the MSDU contained in the A-MSDU subframe are not equal to the values contained in Address 3 and/or Address 4 of the frame.

Otherwise, the addressing of the frame containing an A-MSDU shall be as follows in this case:

- Address 1 is the MAC address of its associated AP (the receiver of the MPDU)
- Address 2 is either the MAC address or the AID of the S1G relay STA (the transmitter of the MPDU)
- Address 3 is the MAC address of its associated AP (the BSSID)
  - If the frame is a PV1 QoS Data frame then Address 3 is not present
- DA in A-MSDU subframe header is the DA of the MSDU (the group address)
- SA in A-MSDU subframe header is the SA of the MSDU (the source address of the group addressed MSDU)

When the frame is a PV1 QoS Data frame and the intended receiver has confirmed storing A3 and/or A4 as described in 10.57 then DA and/or SA should not be present in either the A3 and/or A4 fields of the frame or in the DA and/of SA field(s) of the A-MSDU subframe header contained in the frame except when the DA and/or SA for the MSDU contained in the frame or in the A-MSDU subframe are different from the stored values.

A MAC service tuple with a destination address that is a group address passed to a root AP from the DS, or received at an S1G relay STA via the WM, is forwarded via the WM using a 3-address frame format.

The addressing of a 3-address frame shall be as follows in this case:

- Address 1 is the DA of the MSDU (the group address)
- Address 2 is the MAC address of the AP (the BSSID)
- Address 3 is the SA of the MSDU (the source address of the group addressed MSDU)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Group addressed MSDUs received via the WM at an S1G relay AP are not forwarded to the WM as a broadcast transmission, but are instead forwarded to the S1G relay STA as specified in 10.3.6. Therefore, group addressed MSDUs in a relay network first travel to the root AP as an individually addressed transmission, after which they travel down the tree as group transmissions by the S1G root AP and the S1G relay AP(s).

10.53.5 Procedures of TXOP sharing for S1G relay operation

10.53.5.1 General

An S1G STA that supports TXOP sharing procedure may set the Relayed Frame field in the Frame Control field of PV1 QoS Data frames (defined in 9.8), the Relayed Frame field in NDP Ack frames, and the Order field in the Frame Control field of an S1G RTS frame to 1. Otherwise, it shall set the Relayed Frame field or Order field in any frame to 0 unless the frame is an NDP Ack frame used for flow control as described in 10.60. The S1G STA may use TXOP sharing to transmit to the S1G relay (S1G relay AP or S1G relay STA) either one PV1 QoS Data frame in the TXOP or the last PV1 QoS Data frame of the TXOP where the TXOP is obtained as described in 10.23.2.4 and the PV1 QoS Data frame has the Ack Policy Indicator subfield equal to 0 and is carried in an MPDU or in an S-MPDU.

Reception of a valid PV1 QoS Data frame with the Relayed Frame field equal to 1 or of an S1G RTS frame with the Order field equal to 1 indicates a relay-shared TXOP.

An S1G STA indicates support of TXOP sharing with implicit Ack using the TXOP Sharing Implicit Ack Support subfield of the S1G Capabilities Information field in the S1G Capabilities element. If dot11TXOPSharingImplicitACKImplemented is true, the S1G STA shall set the TXOP Sharing Implicit Ack Support subfield to 1 in transmitted frames containing the S1G Capabilities element. Otherwise, the S1G STA shall set the TXOP Sharing Implicit Ack Support subfield to 0.

A non-S1G STA shall not perform TXOP sharing.

An S1G relay entity shall not perform TXOP sharing if the S1G relay STA and S1G relay AP are operating in different primary channels for the duration of the TXOP. An S1G relay that performs TXOP sharing shall use a channel width that is the same or narrower than the channel width indicated by the STA that initiated the TXOP.

The sequence of frames exchanged over the first hop and second hop during a relay-shared TXOP depends on the acknowledgment procedure used by the S1G relay.

When an S1G relay (S1G relay STA or S1G relay AP) receives a valid PV1 QoS Data frame with the Relayed Frame field in the Frame Control field equal to 1, the S1G relay may acknowledge the received PV1 QoS Data frame using the implicit or explicit Ack procedure. The S1G relay shall not acknowledge the received PV1 QoS Data frame using either implicit or explicit Ack procedure if the Relayed Frame field in the Frame Control field is equal to 0 in the received PV1 QoS Data frame.

NOTE—The frames transmitted over the first hop and second hop can be sent at two different MCSs.

For error recovery purposes, during a relay-shared TXOP, the TXOP owner may transmit its next PPDU when the CS mechanism (see 10.3.2.1) indicates that the medium is idle at the TxPIFS slot boundary (defined in 10.3.7) (this transmission is a continuation of the current TXOP or SP).

10.53.5.2 Explicit Ack procedure

Throughout this subclause, a Response Indication of Long Response is signaled in an NDP Ack frame by setting the Idle Indication field to 1 and the Duration field to 0 and a Response Indication of No Response is signaled by setting the Idle Indication field to 0 and the Duration field to 0 (see 10.3.2.17).

In order to start a relay-shared TXOP, a non-AP STA (AP) sends a PV1 QoS Data frame addressed to the S1G relay AP (S1G relay STA) with the Relayed Frame field equal to 1. In order to use the explicit Ack procedure, an S1G relay AP (S1G relay STA) addressed by an RTS frame shall respond with an NDP CTS frame with the Duration field set as described in 10.53.5.4.

When using the explicit Ack procedure, the S1G relay AP (S1G relay STA) shall signal a Response Indication of Long Response in the NDP Ack frame that is transmitted as an acknowledgment to the non-AP STA (AP). In addition it shall set the Relayed Frame field of the NDP Ack frame to 1. Otherwise, it shall signal a Response Indication of No Response in the NDP Ack frame and shall set the Relayed Frame field to 0.

When using the explicit Ack procedure, the S1G relay STA (S1G relay AP) shall forward the previously received PV1 QoS Data frame to the AP (non-AP STA), SIFS after the S1G relay AP (S1G relay STA) sent the NDP Ack frame to the non-AP STA (AP). In addition, the S1G relay STA (S1G relay AP) may protect the forwarded frame with a protection mechanism such as RTS/CTS exchange. Upon receipt of the relayed PV1 QoS Data frame, the AP (non-AP STA) shall transmit an NDP Ack frame to the S1G relay STA (S1G relay AP), which shall signal a Response Indication of No Response terminating this relay-shared TXOP.

NOTE—The description above applies to both uplink and downlink procedures with the non-AP STA (AP), i.e., either the non-AP STA or the AP is the TXOP owner for the TXOP sharing session.

10.53.5.3 Implicit Ack procedure

A STA that supports implicit Ack procedure and intends to transmit a frame to a next hop STA via an S1G relay (S1G relay STA or S1G relay AP) using the implicit Ack procedure needs to enable the implicit Ack procedure (and acquire the required information to operate using implicit Ack) with the S1G relay. The implicit Ack procedure is enabled between the STA and the S1G relay (S1G relay STA or S1G relay AP) if

- The STA is an AP to which the S1G relay STA of the S1G relay is associated and the S1G relay STA has successfully transmitted to the AP a STA Information Announcement frame containing the AID that the S1G relay AP of the S1G relay has assigned to the next hop non-AP STA.
  - The S1G relay STA may transmit a STA Information Announcement frame to its associated AP that supports the implicit Ack procedure when the S1G relay AP either assigns an AID to the next hop non-AP STA during association or changes the AID of the non-AP STA as described in 10.20.
  - The AP shall determine the PARTIAL_AID of the next hop non-AP STA as described in 10.21 using the BSSID of the S1G relay AP's BSS and the AID of the next hop non-AP STA to be able to use the implicit Ack procedure.
- The STA is a non-AP STA that is associated to the S1G relay AP and the S1G relay AP has transmitted to the STA an S1G Relay element with the Parent AP BSSID field containing the BSSID of the BSS of the parent AP with which the S1G relay STA of the S1G relay is associated.
  - The non-AP STA shall determine the PARTIAL_AID and the COLOR of the next hop AP as described in 10.21 using the BSSID and COLOR values used by the next hop AP to be able to use the implicit Ack procedure.

After the implicit Ack procedure is enabled and all the required information is acquired as described above, the implicit Ack may be used to acknowledge eliciting PV1 QoS Data frames carried in

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

S1G_SHORT/S1G_LONG PPDUs (i.e., that contain a PARTIAL AID, UPLINK_INDICATION, and COLOR in their PHY header).

In order to share the TXOP with the S1G relay, a STA may start the TXOP by sending to the S1G relay an S1G RTS frame with the Order field set to 1 or a PV1 QoS Data frame that has the Relayed Frame field set to 1. An S1G relay (S1G relay STA or S1G relay AP) that is the intended receiver of the S1G RTS frame which intends to use the implicit Ack procedure shall respond with an NDP CTS frame with the Duration field set as described in 10.53.5.4.

When an S1G relay receives a PV1 QoS Data frame during a relay-shared TXOP, the S1G relay may directly forward the received frame without sending back an acknowledgment frame to the transmitter of the frame. If the PV1 QoS Data frame was preceded by an RTS frame then the S1G relay should protect the forwarded frame by sending an RTS frame to the intended receiver as described in 10.53.5.4.

If the MPDU is transmitted by a non-AP STA that is associated to an S1G relay AP, to the AP, then the S1G relay AP forwards the received MPDU to the AP to which it is associated, using SIFS. After transmitting the MPDU, the non-AP STA shall wait for an AckTimeout interval to detect a PPDU that would acknowledge the reception of the MPDU as described in 10.3.2.11. An indication of reception allows the frame exchange sequence to continue, or to end without retries, as appropriate for the particular frame exchange sequence in progress.

If the MPDU is transmitted by an AP to an S1G relay STA, then the S1G relay STA forwards the received MPDU to the non-AP STA that is associated to the S1G relay AP, using SIFS. After transmitting the MPDU, the AP shall wait for an AckTimeout interval to detect a PPDU that would acknowledge the reception of the MPDU as described in 10.3.2.11. An indication of reception allows the frame exchange sequence to continue, or to end without retries, as appropriate for the particular frame exchange sequence in progress. If the RA of the forwarded MPDU is different from the DA of the MPDU transmitted by the AP, then the S1G relay STA shall use the explicit Ack procedure.

10.53.5.4 Relay-shared TXOP protection mechanisms

An S1G STA that supports TXOP sharing should initiate a relay-shared TXOP by sending an S1G RTS frame as the first frame in the exchange under EDCA. The S1G STA may set the Order field of the RTS frame to 0 to indicate that the duration of the initiated TXOP is limited as described in 10.23.2.9 and that it expects an NDP CTS frame whose Duration field is set as described in 10.3.2.9. Otherwise, it may set the Order field to 1 to indicate that the duration of the initiated TXOP can be extended (i.e., it is not necessarily limited as described in 10.23.2.9) and that it expects an NDP CTS frame whose Duration field is set as described in this subclause.

An S1G relay that is the intended receiver of the S1G RTS frame with the Order field equal to 1 and intends to use the relay-shared TXOP responds with an NDP CTS frame with a value of the Duration field that depends on the acknowledgment procedure it shall use during this relay-shared TXOP:

— If explicit Ack procedure (see 10.53.5.2) then the Duration field of the NDP CTS frame shall be set to a value D:

$$T_{\text{RTS}} + T_{\text{PENDING}} - T_{\text{CTS}} \leq D \leq T_{\text{TXOP\_REMAINING}} - T_{\text{PPDU}}$$

where

T_{RTS} is the value obtained from the Duration/ID field of the S1G RTS frame that elicited the response

T_{CTS} is the time, in microseconds, between the end of the PPDU carrying the RTS frame and the end of the NDP CTS frame

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

$T_{PENDING}$	is the estimated time required for the transmission of the frame to be forwarded, its response if required, protection frame exchange sequences if required, plus applicable IFS durations
$T_{TXOP\_REMAINING}$	is equal to any T_{TXOP} as defined in 9.2.5.2 minus T_{RTS}
T_{PPDU}	is the time required for transmission of the current PPDU

— If implicit Ack procedure (see 10.53.5.3), then the Duration/ID field of the NDP CTS frame shall be set according to 9.2.5.6. When using the implicit Ack procedure, upon reception of a PV1 QoS Data frame that is preceded by the transmission of an NDP CTS frame as described above, the S1G relay (S1G relay STA or S1G relay AP) should protect the PV1 QoS Data frame transmission with an RTS/CTS protection mechanism. The Duration/ID field of the RTS frame shall be less than or equal to T_{TXOP} for that AC, as defined in 9.2.5.2, minus the estimated time since the start of the reception of the RTS frame with the Order field equal to 1 that was sent by the relay-shared TXOP owner.

An S1G relay (S1G relay STA or S1G relay AP) that uses the relay-shared TXOP may transmit an (NDP) CF-End frame after successfully forwarding the PV1 QoS Data frame if the remaining duration is long enough to transmit this frame.

An S1G relay that is the intended receiver of the S1G RTS frame with the Order field equal to 0 responds with an NDP CTS frame as described in 10.3.2.9.

10.53.6 S1G relay discovery procedure

A single hop link is an one-hop link between a non-AP STA and the root AP.

A relay link is a multi-hop link between a non-AP STA performing an active scan for S1G relays, and the S1G root AP through the S1G relay.

A non-AP STA that performs active scanning may use the Probe Request frame with an S1G Relay Discovery element when relay discovery procedure is implemented. A non-AP STA with dot11RelayDiscoveryOptionImplemented equal to true may transmit a Probe Request frame including an S1G Relay Discovery element with link budget information for the single hop link and additional QoS requirements for the relay link. This information shall be conveyed using the S1G Relay Discovery element as defined in 9.4.2.206 if present. The formulas for calculating link budget and QoS requirements are implementation specific.

An S1G relay with dot11RelayDiscoveryOptionImplemented equal to true that receives a Probe Request frame becomes eligible to be an S1G relay for this non-AP STA if the link budget and QoS requirements are met and the SSID and other capability parameters match. If these requirements are met, an S1G relay may respond to the non-AP STA with a Probe Response frame, or a PV1 Probe Response frame as an S1G relay candidate for this non-AP STA. When a non-AP STA uses the S1G Relay Discovery element to indicate the DL/UL maximum/minimum/mean data rates of the direct link or the Delay Bound Requirement of the connection through the S1G relay in the Probe Request frame, the S1G relay may also use those parameters as the criteria of responding to the Probe Request frame. The principle for this operation is to reduce the number of Probe Response, or PV1 Probe Response frames sent from S1G relays.

An S1G relay may optionally include link budget information along with other information in S1G Relay Discovery elements such as DL/UL maximum/minimum/mean data rates, relay STA count or channel utilization information in a Probe Response frame, a PV1 Probe Response frame, or a Beacon frame. This information is used for the non-AP STA, when multiple Probe Response, or PV1 Probe Response, frames are received, to select an S1G relay among multiple S1G relay candidates.

An S1G relay with dot11RelayDiscoveryOptionImplemented equal to true that receives a Probe Request frame with the S1G Relay Discovery element from a non-AP STA may respond to the non-AP STA with a

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

probe response frame with the S1G Relay Discovery element carrying the Information Not Available field set to 1 to indicate that for the remaining duration of the current association it will not provide any requested relay discovery information.

10.54 Group AID

An S1G STA with dot11GroupAIDActivated equal to true supports the implementation of group addressed traffic delivery using group AID. An S1G STA with dot11GroupAIDActivated equal to true shall set the Group AID Support subfield in the S1G Capabilities element it transmits to 1. Otherwise, it shall set it to 0.

A group AID is an AID that is assigned by an S1G AP to identify a group of S1G STAs. A group AID corresponds to a bit in the traffic-indication virtual bitmap. An S1G AP signals the presence of group addressed BUs that correspond to a group AID using the same signaling as the signaling of individually addressed BUs, i.e., the AP sets the bit corresponding to the group AID in the traffic-indication virtual bitmap to 1 when BUs are present, and sets it to 0 otherwise.

An S1G AP shall not follow this subclause to transmit a group addressed frame to a STA that has not requested delivery using a group AID for that group address.

An S1G STA with dot11GroupAIDActivated equal to true that has a group address may request a group AID from the S1G AP to which it is associated to by sending an AID Switch Request frame. A SIFS after receiving the AID Switch Request frame, the S1G AP that supports group AID responds with an AID Switch Response frame that contains the assigned group AID that corresponds to that group address and the group listen interval as described in 10.20. The S1G AP may assign different group AIDs to S1G STAs that have the same group address but different group listen intervals. The S1G STA should maintain the link between the assigned group AID to its group address and group listen interval.

An S1G AP that has negotiated a group AID shall indicate the presence of group addressed BUs corresponding to the group AID in the TIM included in the S1G Beacon frame that is sent every group listen interval, following the expiration of a counter that corresponds to the AID Switch Count field included in the AID Response element containing the group AID and that started upon transmission of that element.

An S1G STA that has negotiated a group AID and has not negotiated TWTs (see 10.46) shall transition to awake state every group listen interval that corresponds to the group AID to receive the S1G Beacon frame, starting from the TBTT or TSBTT that follows the expiration of a counter that corresponds to the AID Switch Count field included in the AID Response element containing the group AID and that started upon receipt of that element. An S1G STA that has negotiated both group AID and TWTs wakes at specific target wake times as defined in 10.46.

For example, when S1G AP with dot11PageSlicingActivated equal to true has data buffered for a group of S1G STAs with dot11PageSlicingActivated equal to true that belong to a group AID, it indicates this condition in the Page Slice element (9.4.2.191) transmitted in a DTIM beacon. The S1G STAs that detect this indication will transition to awake state at the assigned beacon interval to determine the TIM and extract the assigned time slots that carry the buffered group data. The S1G AP transmits the buffered group data within the assigned time slots for the S1G STAs' reception.

The S1G AP that has indicated the presence of group addressed BUs for a given group AID in an S1G Beacon frame shall deliver these BUs using a PV0 frame with the group address that corresponds to the group AID in the A1 field (see 9.8.3.2) and setting the partial AID as described in 10.21. These group addressed frames should be delivered during the beacon interval or short beacon interval that follows the S1G Beacon frame or within negotiated TWT SPs if that group AID is assigned to a non-AP STA that follows 10.46.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE—An S1G STA that has a group AID assigned for a particular group address may receive duplicate group addressed BUs due to different group delivery procedures.

10.55 Traveling pilot operation

An S1G STA with dot11S1GTravelingPilotOptionActivated equal to true shall set the Traveling Pilot Support field in the S1G Capabilities Info field of the S1G Capabilities element, as described in 9.4.2.199 to

— 1 if reception of traveling pilots is supported only for one space-time stream
— 3 if reception of traveling pilots is supported for both one and two space-time streams

An S1G STA with dot11S1GTravelingPilotOptionActivated equal to false shall set the Traveling Pilot Support field in the S1G Capabilities element to 0.

An S1G STA shall not transmit a PSDU with the TXVECTOR parameter TRAVELING_PILOTS equal to 1 to an S1G STA unless the Traveling Pilot Support field of the S1G Capabilities element received from that STA contained a value of 1 or 3 and dot11S1GTravelingPilotOptionActivated is true (if there is more than one intended receiver, then this requirement applies for each intended receiver).

10.56 Bitmap protection for NDP BlockAck frames

NDP BlockAck frames are protected by the 4 bit CRC of the S1G SIG-A field, which might not be enough to protect the BlockAck Bitmap field contained in the frame. This subclause describes a mechanism that offers increased protection for the BlockAck Bitmap field of NDP BlockAck frames.

The originator of an NDP BlockAck (NDP_1M BlockAck or NDP_2M BlockAck) frame (see 23.3.12.2.6) shall protect the BlockAck Bitmap field of the NDP BlockAck frame (shown in Figure 23-22 (NDP CMAC PPDU body field of the NDP_1M CTS frame) and Figure 23-23 (NDP CMAC PPDU body field of the NDP_2M CTS frame)) by using the encoding procedure defined in this subclause.

Initially the bit sequences [B3: B10] for NDP_1M BlockAck and [B3:B18] for NDP_2M BlockAck frames are set as described in 10.25.6.5 or 10.3.2.12. Then, prior to transmission, the originator encodes the bit sequences following the procedure below.

Encoding procedure:

For an NDP_1M BlockAck frame:
— [B3: B10] = XOR([B3: B10], [B17: B24]);

For an NDP_2M BlockAck frame
— [B3: B18] = XOR([B3: B18], [B21: B36]);

The intended recipient shall perform the same procedure to decode the bit sequences [B3: B10] for NDP_1M BlockAck and [B3:B18] for NDP_2M BlockAck frames.

10.57 Generation of PV1 MPDUs and header compression procedure

An S1G STA that sets the STA Type Support subfield in a transmitted S1G Capabilities element to 0 or 1, as described in 10.62, shall set the PV1 Frame Support subfield in the S1G Capabilities element to 1. An S1G STA that sets the STA Type Support subfield in a transmitted S1G Capabilities element to 2 may set the PV1 Frame Support subfield in the S1G Capabilities element to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An S1G STA shall not transmit PV1 MPDUs with the Type subfield equal to 0, 1 or 3 to a peer STA unless the PV1 Frame Support subfield of the S1G Capabilities element received from the peer STA contained a value of 1. An S1G STA with dot11PV1MACHeaderOptionImplemented equal to true shall use the PV1 format instead of the PV0 format to transmit QoS Data, Action, and Action No Ack frames that are individually addressed to a peer STA from which it has received an S1G Capabilities element with PV1 Frame Supported subfield equal to 1.

A non-S1G STA shall not transmit a PV1 frame.

The header compression procedure enables S1G STAs to store addresses and/or update security parameters at the receiver. An S1G STA with dot11PV1MACHeaderOptionImplemented equal to true shall set dot11RSNAProtectedManagementFramesActivated to true and dot11RSNAUnprotectedManagementFramesAllowed to false.

An S1G STA with dot11PV1MACHeaderOptionImplemented equal to true may include a Header Compression element in Header Compression frames. The STA may include the Header Compression element in (Re)Association Request frames and (Re)Association Response frames when management frame protection is not negotiated for the association. The STA may set the PV1 Data Type 3 Supported subfield in the Header Compression element to 1 to indicate that it supports reception of PV1 frames that have the Type subfield in the Frame Control field equal to 3.

After association, an S1G STA with dot11PV1MACHeaderOptionImplemented equal to true may transmit Header Compression frames and PV1 frames. An S1G STA shall not transmit PV1 frames with Type subfield equal to 3 to a peer STA unless the PV1 Data Type 3 Supported subfield is 1 in the most recently received Header Compression element sent by the peer STA. An S1G STA in an IBSS shall not transmit PV1 frames with a value of the Type subfield equal to 0 or 1.

NOTE—A PV1 frame is an MPDU with Protocol Version field in the Frame Control field equal to 1 (see 9.8).

The header compression procedure uses a Header Compression element, which is referred to as a header compression request or a header compression response, depending on the Request/Response subfield setting of the Header Compression element.

A STA that transmits PV1 frames with Type subfield equal to 0 shall include the A3 field if the value of this field

— Is not equal to the address identified by the A1 field and an A3 is not stored at the receiver.
— Is not equal to the A3 stored at the receiver.

Otherwise, the A3 field shall not be included in the frame.

A STA that transmits PV1 frames with Type subfield equal to 0 shall include the A4 field if the value of this field

— Is not equal to the address identified by the A2 field and an A4 is not stored at the receiver.
— Is not equal to the A4 stored at the receiver.

Otherwise, the A4 field shall not be included in the frame.

An S1G STA indicates a request to store address fields by sending a header compression request with the Store A3 and/or Store A4 subfields equal to 1. Upon receipt of such a request, the receiving STA shall respond with a header compression response indicating which of the optional fields it stores, by setting the Store A3 and/or Store A4 subfields in the transmitted header compression response to 1. Stored address fields can subsequently be omitted from the MAC header of PV1 frames transmitted by the STA that sent the header compression request. Address A3 and/or A4 fields for which the header compression response

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

indicated 0 are not stored at the receiver and cannot be omitted by the transmitter when the A3 and/or A4 fields contain values that are different from the A1 and/or A2 fields of the same. The receiver stores one A3 and one A4 per transmitter. The stored A3 and A4 addresses shall be used at the receiver for all frames from the transmitter that omit the stored addresses.

An S1G STA indicates a request to update security parameters by sending a header compression request with the CCMP Update subfield equal to 1. The receiver STA shall respond with a header compression response acknowledging receipt of the updated security parameters. The receiver STA shall compare the received BPN value to the current locally stored BPN value. If the received BPN value is greater than the locally stored BPN value, the receiver STA shall update the locally stored BPN value. Otherwise, the receiver STA shall not update the locally stored BPN value.

After sending a header compression request, an S1G STA shall postpone the transmission of PV1 frames that do not include the fields that were requested to be stored to the recipient of the header compression request until it receives the corresponding header compression response.

After receiving a header compression request, an S1G STA shall store and activate the included addresses it intends to store and/or the security information included in the header compression request before transmitting the corresponding header compression response.

When no header compression response has been received in response to a header compression request within dot11HeaderCompressionResponseTimeout, an S1G STA shall transmit another header compression request.

A STA that receives a PV1 frame with one or more compressed addresses that it has not stored or which causes a decryption error should transmit an unsolicited header compression response to the transmitter of the PV1 frames, in which the Store A3, and Store A4 fields are all equal to 0. The unsolicited header compression response shall specify the SN space of the received PV1 frame using the PTID subfield and Management subfield of the CCMP Update field if the received frame caused a decryption error, where the CCMP Update field shall indicate the stored values for the BPN and key ID that correspond to the received PV1 frame.

A STA that has previously transmitted PV1 frames of a given SN space to a peer STA and that receives an unsolicited header compression response from the peer STA relative to that SN space shall transmit a header compression request to the transmitter of the header compression response. The header compression request shall include all the addresses that the transmitting STA requests to be stored at the receiver and/or the security information that corresponds to the indicated SN space.

10.58 Transmission of an NDP CMAC PPDU

An S1G STA transmitting an NDP CMAC PPDU shall use the following TXVECTOR parameters:

- NDP_INDICATION set to 1
- NUM_STS indicates one space-time stream
- APEP_LENGTH set to 0
- NUM_USERS set to 1

An S1G STA in an IBSS shall not transmit an NDP CMAC PPDU, except for an NDP Ack, NDP BlockAck or NDP Probe Request frame.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

10.59 S1G_Long operation

An S1G STA with dot11S1GLONGOptionActivated equal to true shall set the S1G_LONG Support field in the S1G Capabilities element to 1. An S1G STA with dot11S1GLONGOptionActivated equal to false shall set the S1G_LONG Support field in the S1G Capabilities element to 0.

An S1G STA shall not transmit a PSDU with the TXVECTOR parameter PREAMBLE_TYPE set to S1G_LONG_PREAMBLE to an S1G STA unless the S1G_LONG Support field of the S1G Capabilities element received from that STA contained a value of 1 and dot11S1GLONGOptionActivated is true.

10.60 S1G flow control

This subclause describes flow control operation for an S1G STA.

NOTE 1—The S1G relay operation can use the flow control mechanism described in this subclause to prevent from the overflow condition.

A STA that supports flow control shall set the Flow Control Supported subfield to 1 in the S1G Capabilities element it transmits. An S1G AP that implements flow control may refuse (re)association or can disassociate a non-AP STA that sets the Flow Control Supported subfield to 0 in the S1G Capabilities element. The S1G AP that refuses (re)association or disassociates the STA shall set the Status Code field in the (Re)Association Response frame or in the Disassociation frame to FLOW_CONTROL_OPERATION_SUPPORTED.

A STA that sets the Flow Control Supported subfield to 1 in the S1G Capabilities element that it transmits may instruct a second STA that sets the Flow Control Supported subfield to 1 in the S1G Capabilities element that it transmits to stop sending Data frames using a flow-control instruction. The STA sending the flow-control instruction is called the flow-controlling STA. A STA that sets the Flow Control Supported subfield to 0 in the S1G Capabilities element that it transmits shall not instruct a second STA to stop sending Data frames using a flow-control instruction as described in this subclause. A STA that is the intended recipient of a flow-control instruction and that correctly receives that instruction is called a flow-controlled STA. A flow-controlled STA does not transmit any Data frames to the flow-controlling STA that transmitted the flow-control instruction, for the amount of time indicated in the flow-control instruction. A flow-control instruction is any of the following:

— A Flow Suspension frame
— A BAT frame with the Flow Control bit in the Frame Control field equal to 1
— A TACK frame with the Flow Control bit in the Frame Control field equal to 1
— A STACK frame with the Flow Control bit in the Frame Control field equal to 1
— An NDP Ack frame with the Relayed Frame field equal to 1 and the Idle Indication field equal to 1 and the Duration field not equal to 0

NOTE 2—The transmission of BAT frames, STACK frames, TACK frames is only permitted within TWT SP as described in 10.46, 10.25, and 10.3.2.11.

The Suspend Duration field of the Flow Suspension frame listed above indicates the length of time during which a flow-controlled STA shall not transmit Data frames to the flow-controlling STA identified by the TA field of the Flow Suspension frame.

The Suspend Duration field of the TACK/BAT/STACK frame listed above indicates the length of time during which a flow-controlled TWT STA shall not transmit Data frames to the flow-controlling STA identified by the TA field of the TACK/BAT frame and the RA field of the frame that elicited the STACK frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The Duration field of the NDP Ack frame listed above indicates the length of time during which a flow-controlled STA shall not transmit Data frames to the flow-controlling STA identified by the RA field of the frame that elicited the NDP Ack frame.

A flow-controlled STA may resume transmission of Data frames addressed to the flow-controlling STA that had previously suspended transmission after the expiration of the time indicated in the Suspend Duration field of a Flow Suspension frame, TACK frame, BAT frame, or TACK frame or in the Duration field of an NDP Ack frame.

A flow-controlling STA may send a Flow Resumption frame to cancel any outstanding flow suspension time for the flow-controlling STA identified by the TA field of the Flow Resumption frame.

A flow-controlled STA that receives a Flow Resumption frame with a BSSID that matches the BSSID of the BSS of which the flow-controlled STA is a member or with an RA field that matches the address of the flow-controlled STA shall cancel any outstanding flow suspension time, and may resume transmission of Data frames to the flow-controlling STA identified by the TA field of the Flow Resumption frame.

A STA should send a next TWT value in the Next TWT Info/Suspend Duration field of the response frame it transmits to a TWT STA if the More Data bit is equal to 0 in the eliciting frame. A STA may send a suspend time value in the Next TWT Info/Suspend Duration field of a response frame it transmits to a TWT STA if the More Data bit is equal to 1 in the eliciting frame.

10.61 Energy limited STAs operation

An S1G STA keeps two timers, ELMaxAwakeTimer and ELRecoveryTimer, for each EL STA; and these timers are initialized upon reception of an EL Operation element from the EL STA:

— The ELMaxAwakeTimer is set to 0.
— The ELRecoveryTimer is set to the value of the Recovery Time field of the EL Operation element.

These timers uniformly count down to 0 when their values are nonzero. Figure 10-153 (EL STA operation) shows an example of the EL STA frame exchanges with the S1G STA.

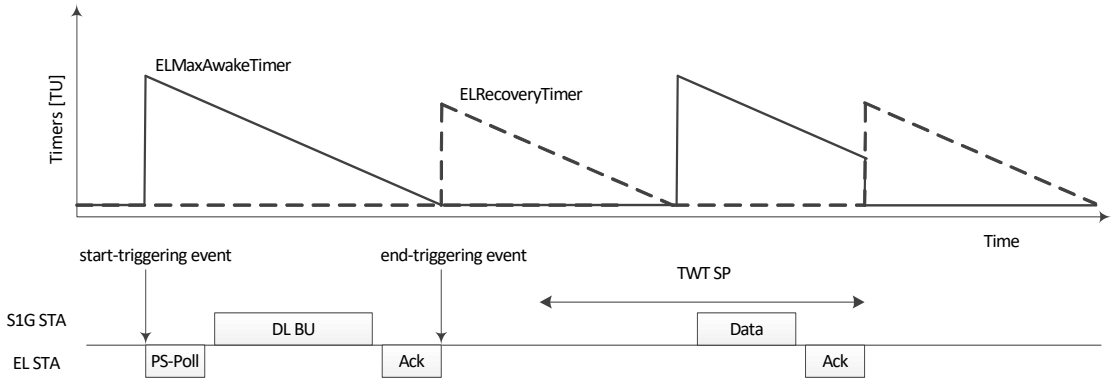

Figure 10-153—EL STA operation

The S1G STA shall not transmit to the EL STA, or cause the EL STA to transmit, a PPDU containing individually addressed frames and whose duration would exceed the value of the ELMaxAwakeTimer.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The S1G STA shall set the ELMaxAwakeTimer to the value of the Max Awake Duration field of the most recently received EL Operation element from the EL STA and the ELRecoveryTimer to 0 when a start-triggering event occurs (see Figure 10-153 (EL STA operation) for an example). A start-triggering event occurs when both ELMaxAwakeTimer and ELRecoveryTimer are 0, and one of the following events that identify a transition of the EL STA from doze to awake state occurs:

— An (NDP) PS-Poll or trigger frame sent by the EL STA is received by the S1G STA.
— A TWT starts for the EL STA, where the TWT corresponds to any TWT agreement that the EL STA has set up with the S1G STA.
— A RAW slot allocated for the EL STA starts, where the RAW slot is scheduled in a RAW scheduled for the EL STA by the S1G STA.
— A TBTT or TSBTT at which the EL STA has to be awake is due, where the TBTT or TSBTT is the time the S1G STA sends an S1G Beacon frame that is intended to be received by the EL STA.

NOTE—An EL STA can send a frame that is not a trigger frame to the S1G STA anytime and the reception of this frame from the S1G STA does not qualify as a start-triggering event.

The S1G STA shall not schedule a transmission of a PPDU carrying an individually addressed MPDU intended for the EL STA, or cause the EL STA to transmit an individually addressed frame until the ELRecoveryTimer has reached 0.

The S1G STA shall set the ELRecoveryTimer to the value of the Recovery Time field of the most recently received EL Operation element from the EL STA and the ELMaxAwakeTimer to 0 when an end-triggering event occurs (see Figure 10-153 (EL STA operation) for an example). An EL STA may indicate the recovery duration in the Duration field of an NDP (PS-Poll-)Ack frame with the Idle Indication field set to 1. An end-triggering event occurs when the ELRecoveryTimer is 0 and one of the following events that identify a transition of the EL STA to doze state occurs:

— An acknowledgment is received from the EL STA as a response to the transmission of a BU, where the BU is sent by the S1G STA in response to an (NDP) PS-Poll or trigger frame generated by the EL STA.
— An acknowledgment is received from the EL STA as a response to of a frame with EOSP field equal to 1, where the frame is sent by the S1G STA.
— An NDP (PS-Poll-)Ack frame is received from the EL STA as a response to a frame generated by the S1G STA, where the NDP (PS-Poll-)Ack frame has an Idle Indication field equal to 1 and a nonzero value of the Duration field.
    — In this case, the ELRecoveryTimer is set to the value of the Duration field of the NDP (PS-Poll-)Ack frame when the Idle Indication field is 1.
— The AdjustedMinimumTWTWakeDuration for a TWT has ended, where the TWT corresponds to any TWT agreement that the EL STA has set up with the S1G STA.
— The RAW slot allocated for the EL STA has ended, where the RAW slot was scheduled in a RAW for the EL STA by the S1G STA.
— The transmission of an S1G Beacon frame has ended, where the S1G Beacon frame is sent at a TBTT or TSBTT at which the EL STA was expected to be awake.
— The transmission of group addressed BU(s) has ended, where the group addressed BU(s) are expected to be received by the EL STA following a DTIM beacon.

When the S1G STA cannot complete frames exchanges within ELMaxAwakeTimer, a new backoff procedure is invoked after stopping the current transmission and once the ELRecoveryTimer has expired.

10.62 S1G BSS type and STA type

Non-AP S1G STAs are categorized into two types, sensor STAs and non-sensor STAs.

A non-AP STA that is a sensor STA shall set the STA Type Support subfield in the S1G Capabilities element it transmits to 1. A non-AP STA that is a non-sensor STA shall set the STA Type Support subfield in the S1G Capabilities element it transmits to 2.

There are three types of S1G BSS that an S1G AP can set up: sensor BSS, non-sensor BSS, or mixed BSS. A sensor BSS only supports sensor STAs. A non-sensor BSS supports only non-sensor STAs. A mixed BSS supports both sensor STAs and non-sensor STAs.

An AP may declare a non-sensor BSS by transmitting the S1G Capabilities element in Beacon frames, Probe Response, or PV1 Probe Response frames in which the STA Type Support subfield is 2 (i.e., it indicates that only non-sensor STAs are allowed to associate and operate with that AP).

An AP may declare a sensor BSS by transmitting the S1G Capabilities element in Beacon frames, Probe Response frames, or PV1 Probe Response frames in which the STA Type Support subfield is 1 (i.e., it indicates that only sensor STAs are allowed to associate and operate with that AP).

An AP may declare a mixed BSS by transmitting the S1G Capabilities element in a Beacon, Probe Response or PV1 Probe Response frame, in which the STA Type Support subfield is 0 (i.e., it indicates that any type of STA is allowed to associate and operate with that AP).

An S1G AP that indicates support for sensor STAs shall not indicate minimum MCS restrictions as specified in 10.6.14.3.

10.63 DBC mechanism for CDMG STAs

10.63.1 General

A CDMG STA supports the operation of variable bandwidth channels according to the channelization specified in E.1. A CDMG infrastructure BSS or PBSS can operate on a 1.08 GHz or 2.16 GHz bandwidth channel. As specified in E.1, each 2.16 GHz channel encompasses two 1.08 GHz channels. A CDMG infrastructure BSS or PBSS shall use the following DBC mechanism when operating in the country that requires the support of variable bandwidth channels operation to mitigate interference between other CDMG and DMG BSSs.

A CDMG AP or PCP shall follow the procedures in 11.1.4.4.2 to initialize a CDMG BSS on a 1.08 GHz or a 2.16 GHz bandwidth channel. An AP or PCP operating the BSS on a 1.08 GHz channel shall periodically transmit DMG Beacon frames (10.3.4.2) on the 2.16 GHz channel that encompasses the 1.08 GHz channel on which the BSS is operating. A CDMG AP or PCP may change the operating bandwidth of its BSS dynamically from 1.08 GHz to 2.16 GHz or vice versa.

A CDMG AP or PCP may request the AP or PCP of an existing CDMG BSS operating on a 2.16 GHz channel (e.g., channel 2) to shift its operating channel to one of the 1.08 GHz channels (e.g., channel 35) within its original 2.16 GHz channel by sending a Channel Splitting Request frame (9.6.28.4) or an Extended Channel Splitting Request frame (9.6.7.43). If the existing CDMG BSS changed its operating channel to one of the 1.08 GHz channels (e.g., channel 35), the CDMG AP or PCP that sends the request frame may then operate a new BSS on the other adjacent 1.08 GHz channel (i.e., channel 36) within the 2.16 GHz channel (i.e., channel 2).

A pair of CDMG APs or PCPs operating on the adjacent 1.08 GHz channels (e.g., channel 35 and channel 6) within a 2.16 GHz channel (i.e., channel 2) should maintain synchronization with each other to mitigate the

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

interference caused by the transmission of the DMG Beacon frame and other frames on the 2.16 GHz channel (i.e., channel 2) according to 10.63.2.3.

10.63.2 CDMG channel access

10.63.2.1 CDMG BSS operating on a 2.16 GHz channel

A CDMG AP or PCP operating an infrastructure BSS or PBSS on a 2.16 GHz channel (e.g., channel 2) shall follow the channel access rules as described in 10.38.

10.63.2.2 CDMG BSS operating on a 1.08 GHz channel

A CDMG AP or PCP operating an infrastructure BSS or PBSS on a 1.08 GHz channel (e.g., channel 35) shall periodically transmit DMG Beacon frames (9.3.4.2) on the 2.16 GHz channel (i.e., channel 2) that encompasses its operating channel (i.e., channel 35). The time interval between two consecutive DMG Beacon frames transmitted on the 2.16 GHz channel shall be no more than aMaxBIDuration. The generation of the DMG Beacon frames shall follow the rules in (11.1.3.3.3).

The AP or PCP that starts an infrastructure BSS or PBSS on a 1.08 GHz channel (e.g., channel 35) shall set a TSF timer to track the beacon interval on the encompassing 2.16 GHz channel (i.e., channel 2). At the beginning of a beacon interval on the 2.16 GHz channel, the AP or PCP shall schedule a notification period (NP) or a BHI (10.38.2) indicated by the DBC Option subfield of the Dynamic Bandwidth Control element (9.4.2.219) contained in each DMG Beacon frame as shown in Figure 10-154 (Example of an AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on both channel 2 and channel 35) and Figure 10-155 (Example of a CDMG AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on channel 2 only), respectively. If a NP is scheduled on the 2.16 GHz channel, at least one BHI shall be scheduled on the 1.08 GHz channel. The NP may include the BTI, A-BFT, and ATI.

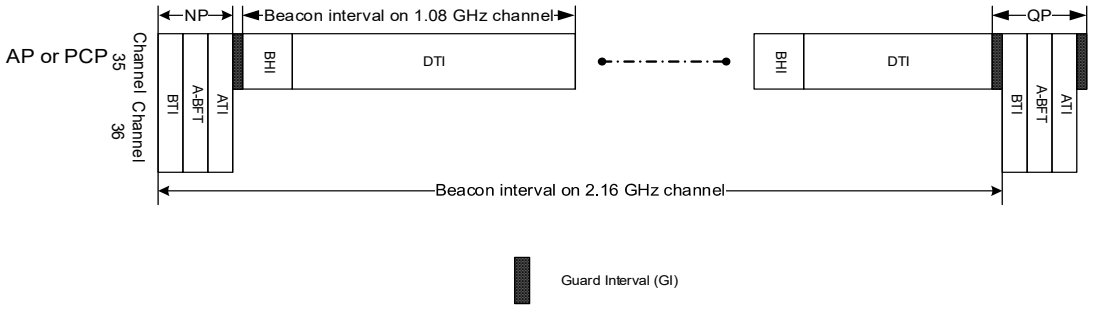

Figure 10-154—Example of an AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on both channel 2 and channel 35

During the BTI on the 2.16 GHz channel, the AP or PCP shall transmit a DMG Beacon frame containing the Dynamic Bandwidth Control element (9.4.2.219) that includes information on the operating status of the BSS through the DBC Control field and Channel Number field. The beacon interval length on the 2.16 GHz channel is indicated by the Beacon Interval field (9.4.1.3) contained in each DMG Beacon frame.

The AP or PCP may also establish an independent beacon interval on its operating 1.08 GHz channel and set another TSF timer to track it. As illustrated in Figure 10-154 (Example of an AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on both channel 2 and channel 35), the beacon interval length on 1.08 GHz channel shall be set as an integer factor of the beacon interval length on 2.16 GHz channel in units of TUs. The maximum length shall be the beacon interval length on the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

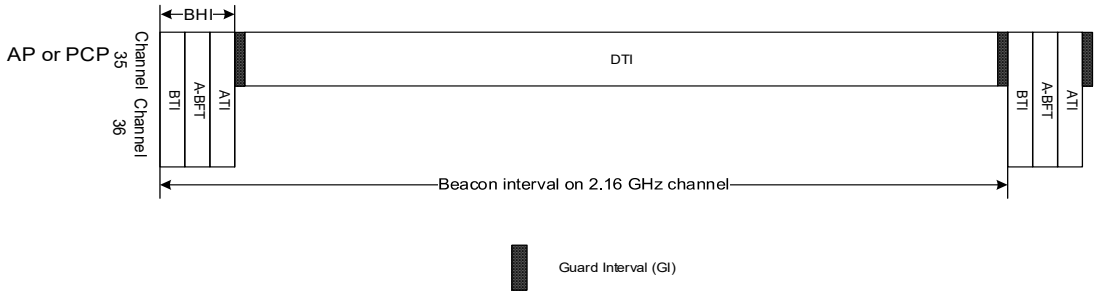

Figure 10-155—Example of a CDMG AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on channel 2 only

2.16 GHz channel. The channel access on the 1.08 GHz shall follow the rules described in 10.38 with a BHI period within each beacon interval. If BHIs are present on the 1.08 GHz channel, the DBC Option subfield of the Dynamic Bandwidth Control element within the DMG Beacon frame is set to 0; otherwise, it is set to 1.

A guard interval (GI) that is an interframe space follows a NP/BHI on the 2.16 GHz channel as shown in Figure 10-154 (Example of an AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on both channel 2 and channel 35) and Figure 10-155 (Example of a CDMG AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on channel 2 only) for CDMG STAs to switch from transmitting and receiving frames on the 2.16 GHz channel to transmitting and receiving frames on the 1.08 GHz channel. The determination of the length of the GI is implementation dependent. At the end of the GI (or the NP/BHI if the GI is not present), the AP or PCP shall be ready to transmit or receive frames on the 1.08 GHz channel indicated by the Channel Number field of the Dynamic Bandwidth Control element.

If a CDMG AP or PCP transmits a DMG Beacon frame with the DBC Option subfield of the Dynamic Bandwidth Control element set to 0, it shall schedule quiet periods (QPs) on a 1.08 GHz channel by scheduling SPs with the AllocationType subfield set to 2 in the Allocation field and the Source AID subfield and Destination AID subfield set to its own AID. The starting times and durations of these QPs shall coincide with the starting times and durations of the NPs on the 2.16 GHz channel. The AP or PCP may also schedule the starting times of the QPs to be earlier than the NPs and the durations of the QPs to be greater than the durations of the NPs to establish a GI before and after each NP as shown in Figure 10-154 (Example of an AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on both channel 2 and channel 35).

If a CDMG AP or PCP transmits a DMG Beacon frame with the DBC Option subfield of the Dynamic Bandwidth Control element set to 1, it may schedule QPs before and after the BHIs to serve as GIs as shown in Figure 10-155 (Example of a CDMG AP or PCP that starts its infrastructure BSS or PBSS on channel 35 by transmitting DMG Beacon frames on channel 2 only). The GIs in this case should be longer than the time taken for all the CDMG STAs to switch from transmitting and receiving frames on the 2.16 GHz channel to transmitting and receiving frames on the 1.08 GHz channel. The determination of the length of the GIs is, however, implementation dependent.

If a non-AP and non-PCP CDMG STA receives a DMG Beacon frame from the CDMG AP or PCP with the BSSID equal to the BSSID of the BSS of which the STA is a member and with the DBC Option subfield of the Dynamic Bandwidth Control element set to 0, the STA shall switch to the 1.08 GHz channel indicated by the Channel Number field of the received Dynamic Bandwidth Control element to receive the DMG Beacon frame transmitted on the corresponding 1.08 GHz channel and follow the beamforming rules in 10.41 and the channel access rules in 10.40 on the 1.08 GHz channel. The non-AP and non-PCP STA may use the BI Offset subfield

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

of the Dynamic Bandwidth Control element in the received DMG Beacon frame to predict the starting time of the BTI on the 1.08 GHz channel. In the following medium time, the non-AP and non-PCP STA should be prepared to receive and transmit frames on the 1.08 GHz channel unless it is assigned by the AP or PCP to monitor the 2.16 GHz common channel, or it communicates with other DMG STAs, or it leaves the current infrastructure BSS or PBSS, or the infrastructure BSS or PBSS ceases its services.

Alternatively, if a non-AP and non-PCP CDMG STA receives a DMG Beacon frame from the CDMG AP or PCP with the BSSID equal to the BSSID of the BSS of which the STA is a member and with the DBC Option subfield of the Dynamic Bandwidth Control element set to 1, the STA shall follow the beamforming rules in 10.41 and the channel access rules in 10.38 within the 2.16 GHz channel during the BHI duration. During the DTI, the STA shall switch to the 1.08 GHz operating channel indicated by the Channel Number field of the received Dynamic Bandwidth Control element to receive and transmit frame following the channel access rules in 10.38 on the 1.08 GHz channel.

10.63.2.3 Synchronization of CDMG infrastructure BSS or PBSSs on the adjacent 1.08 GHz channels within a 2.16 GHz channel

A CDMG AP or PCP setting up an infrastructure BSS or PBSS on a 1.08 GHz channel (e.g., channel 35) that has a CDMG BSS established on the adjacent 1.08 GHz channel (i.e., channel 36) within the same 2.16 GHz channel (i.e., channel 2) should follow the procedures below to maintain synchronization.

A CDMG AP or PCP shall scan the 2.16 GHz channel (e.g., channel 2) that encompasses the 1.08 GHz channel (e.g., channel 36) on which the CDMG AP or PCP is going to set up its BSS for DMG Beacon frames. If the CDMG AP or PCP received a DMG Beacon frame containing a Dynamic Bandwidth Control element with the Channel Splitting subfield set to 1, the Channel Number field indicating the existing AP or PCP works on a 1.08 GHz channel, and the Adjacent Channel Occupancy subfield set to 1, the AP or PCP may send an Extended Notification Period Request frame (9.6.7.41) during the following ATI of the BSS indicated by the BSSID field of the received DMG Beacon frame to request the existing AP or PCP to allocate time for NPs/BHI to transmit DMG Beacon frames on the encompassing 2.16 GHz channel with the NP/BHI Duration field in the Extended Notification Period Request frame indicating the requested duration of NPs/BHIs.

Alternatively, the scanning AP or PCP may attempt to associate with the infrastructure BSS or PBSS indicated by the BSSID field of the received DMG Beacon frame following the rules in 11.3 and subsequently send a Notification Period Request frame (9.6.29.2). A non-AP and non-PCP CDMG STA within an infrastructure BSS or PBSS operating on a 1.08 GHz channel may send a Notification Period Request frame (9.6.29.2) during the ATI, SP, or CBAP to request the AP or PCP to allocate time for NPs/BHIs to transmit DMG Beacon frames on the encompassing 2.16 GHz channel with the -NP/BHI Duration field in the Notification Period Request frame indicating the requested duration of NPs/BHIs.

If a CDMG AP or PCP receives a Notification Period Request frame or an Extended Notification Period Request frame, it may allocate QPs on its operating 1.08 GHz channel at the same recurring position in each beacon interval of the 2.16 GHz channel and reply with a Notification Period Response frame (9.6.29.3) or an Extended Notification Period Response frame (9.6.7.42) containing a Dynamic Bandwidth Control element with the TBTT Offset field indicating the target starting time of the allocated NPs/BHIs and the NP/BHI Duration field and the Adjacent NP/BHI Duration field indicating the lengths of the NPs/BHIs on the 2.16 GHz channel of itself and the scanning AP or PCP. The CDMG AP or PCP may schedule the starting times of the QPs to be earlier than the NPs and the durations of the QPs to be greater than the durations of the NPs to establish a GI before and after each NP/BHI as shown in Figure 10-156 (Two APs or PCPs with NPs arranged consecutively) and Figure 10-157 (Two APs or PCPs with BHIs arranged apart from each other). The AP or PCP shall scan for DMG Beacon frames in the allocated NPs to determine if a new BSS has been established on the adjacent 1.08 GHz channel.

If a CDMG STA receives a Notification Period Response frame or Extended Notification Period Response frame addressed to it, it may establish an infrastructure BSS or PBSS on the 1.08 GHz channel adjacent to the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

channel indicated in the Channel Number field of the Dynamic Bandwidth Control element and become the AP or PCP using the following steps. The scanning AP or PCP shall start to transmit DMG Beacon frames at the start of the allocated NP/BHI indicated by the TBTT Offset field of the Dynamic Bandwidth Control element and set a TSF timer to track its beacon interval on the 2.16 GHz channel. The duration of the beacon interval on the 2.16 GHz channel shall be equal to the Beacon Interval field in the received Notification Period Response frame or an Extended Notification Period Response frame. The duration of NP/BHI on the 2.16 GHz channel shall be set to the value of the Adjacent NP/BHI Duration field of the Dynamic Bandwidth Control element in the received Notification Period Response frame or an Extended Notification Period Response frame. The scanning AP or PCP shall continue to receive the DMG Beacon frames from the existing AP or PCP during the NPs/BHIs starting at the time obtained from the Beacon Interval field minus the TBTT Offset field from the beginning of each beacon interval on the 2.16 GHz channel with the length indicated by the NP/BHI Duration field of the Dynamic Bandwidth Control element in the previously received Notification Period Response frame or Extended Notification Period Response frame and maintain synchronization by adjusting its TSF to match the Timestamp field (9.4.1.10) in the received DMG Beacon frames transmitted in these NPs/BHIs. The scanning AP or PCP shall also use the DBC Option subfield of the Dynamic Bandwidth Control element in each DMG Beacon frame to announce whether the beacon interval on its 1.08 GHz operating channel is present or not as described in 10.63.2.2.

A CDMG AP or PCP operating on a 1.08 GHz channel may also actively allocate reserved NPs/BHIs on the 2.16 GHz channel to allow a new CDMG BSS to be established on the adjacent 1.08 GHz channel. The CDMG AP or PCP may allocate QPs on its operating 1.08 GHz channel at the same recurring position in each beacon interval of the 2.16 GHz channel and announce the presence of the reserved NPs/BHIs by transmitting DMG Beacon frames on the 2.16 GHz channel containing a Dynamic Bandwidth Control element with the Channel Splitting subfield equal to 1, the Adjacent Channel Occupancy subfield equal to 1, and the Adjacent NP/BHI Duration field nonzero. The TBTT Offset field and the Adjacent NP/BHI Duration field in the Dynamic Bandwidth Control element indicate the target starting time and the duration of the reserved NPs/BHIs, respectively. The AP or PCP shall scan for DMG Beacon frames in the reserved NPs to determine if a new BSS has been established on the adjacent 1.08 GHz channel.

If a CDMG AP or PCP receives a DMG Beacon frame on the 2.16 GHz channel containing a Dynamic Bandwidth Control element with the Channel Splitting subfield set to 1, the Adjacent Channel Occupancy field set to 1, and the Adjacent NP/BHI Duration field nonzero, it may establish an infrastructure BSS or PBSS on the 1.08 GHz channel adjacent to the channel indicated in the Channel Number field of the Dynamic Bandwidth Control element using the following steps. The AP or PCP shall continue to scan for DMG Beacon frames on the 2.16 GHz channel during the reserved NPs/BHIs indicated by the TBTT Offset field of the Dynamic Bandwidth Control element for an interval of at least aMinChannelTime. If it does not receive any valid DMG Beacon frame, it may start a new BSS by transmitting a DMG Beacon frame at the start of the reversed NP/BHI and set a TSF timer to track its beacon interval on the 2.16 GHz channel. The duration of the beacon interval on the 2.16 GHz channel shall be equal to the Beacon Interval field in the received DMG Beacon frame of the existing AP or PCP. The scanning AP or PCP shall continue to receive the DMG Beacon frames in NPs/BHIs of the existing AP or PCP operating on the adjacent 1.08 GHz channel to maintain synchronization by adjusting its TSF to match the Timestamp field (9.4.1.10) in the received DMG Beacon frames. The scanning AP or PCP shall also use the DBC Option subfield of the Dynamic Bandwidth Control element contained in each DMG Beacon frame to announce whether the beacon interval on its 1.08 GHz operating channel is present or not described in 10.63.2.2.

The NPs/BHIs of the two APs or PCPs operating on the adjacent 1.08 GHz channels within a 2.16 GHz channel may be arranged consecutively without interspaces to reduce the number of times they need to switch between transmitting and receiving frames on the 2.16 GHz channel and the 1.08 GHz channels.

Figure 10-156 (Two APs or PCPs with NPs arranged consecutively) shows an example of two APs establishing BSSs on channels 35 and 36, respectively, with two NPs, NP 1 of AP 1 and NP 2 of AP 2, arranged consecutively without interspaces. The same arrangement might apply to PCPs establishing PBSSs. Figure 10-157 (Two APs or PCPs with BHIs arranged apart from each other) shows another example of

two APs establishing BSSs on channels 35 and 36, respectively, with two BHIs, BHI 1 of AP 1 and BHI 2 of AP 2, arranged arbitrarily apart from each other. The same arrangement might apply to PCPs establishing PBSSs.

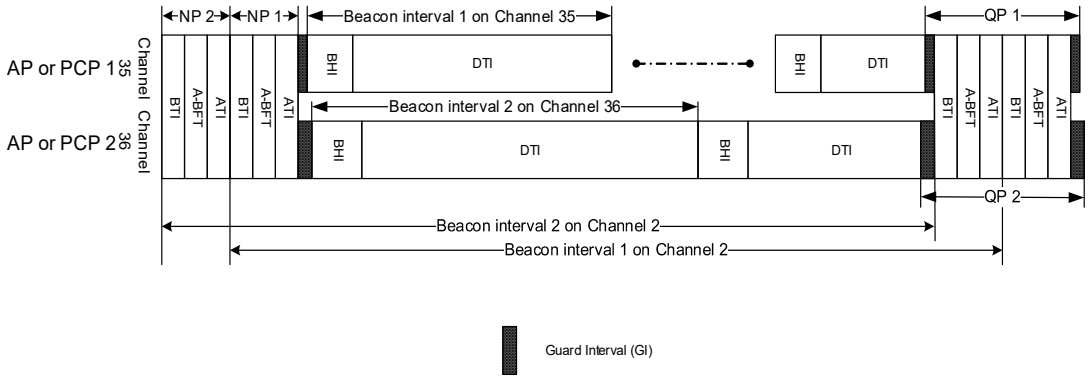

Figure 10-156—Two APs or PCPs with NPs arranged consecutively

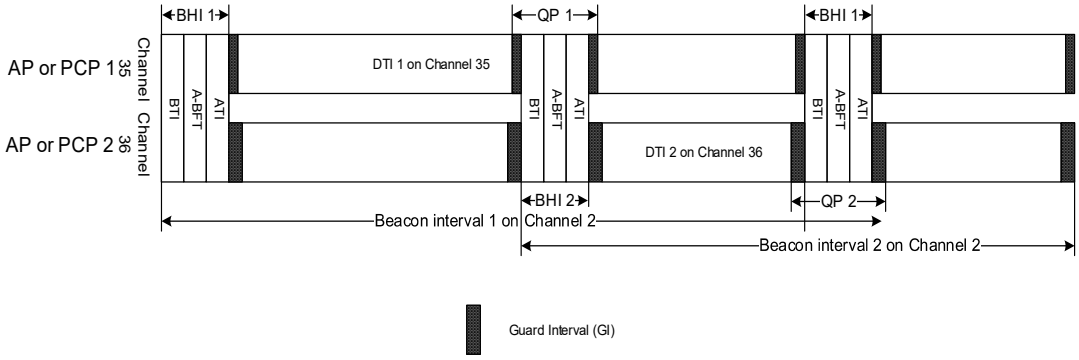

Figure 10-157—Two APs or PCPs with BHIs arranged apart from each other

If a CDMG AP or PCP operating on a 1.08 GHz channel with the adjacent 1.08 GHz channel occupied by another CDMG BSS does not receive any DMG Beacon frame transmitted by the CDMG AP or PCP operating on the adjacent 1.08 GHz channel in the assigned NPs/BHIs for a period of 4×aMinBTIPeriod beacon intervals on the 2.16 GHz channel, starting from when the last frame is received from the neighboring AP or PCP, it may proceed to make changes to the assigned NPs/BHIs on the 2.16 GHz channel. The AP or PCP may continue to allocate a NP/BHI on 2.16 GHz channel at the same position to allow another AP or PCP to establish a new BSS on the adjacent 1.08 GHz channel as described above or it may stop allocating QPs on its operating channel that correspond to the NPs/BHIs on 2.16 GHz channel of the BSS operating on the adjacent 1.08 GHz channel. Figure 10-158 (Service cessation for an AP or PCP on channel 35) shows an example that an AP or PCP can cease its service on channel 35, a 1.08 GHz channel.

Copyright © 2025 IEEE. All rights reserved.

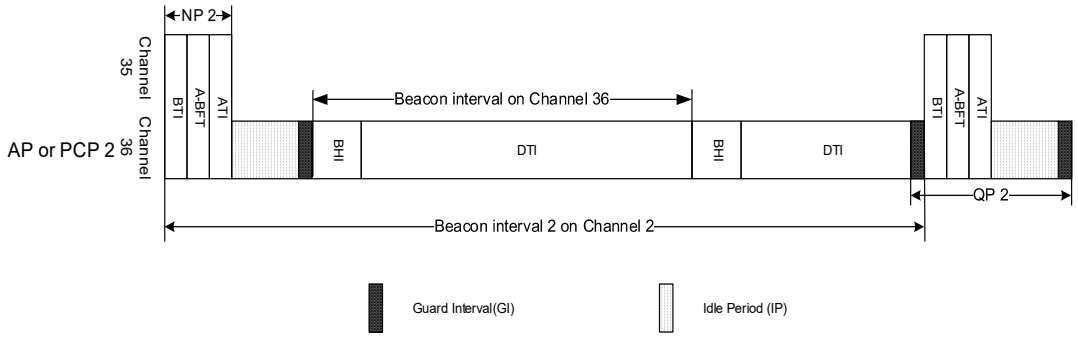

Figure 10-158—Service cessation for an AP or PCP on channel 35

The CDMG AP or PCP may also move its TBTT (11.29.2) on the 2.16 GHz channel (e.g., channel 2) backward so that its NPs/BHIs are followed closely by the BHI on its 1.08 GHz operating channel (e.g., channel 36) as illustrated in Figure 10-159 (Moving TBTT by a neighboring AP or PCP on channel 2).

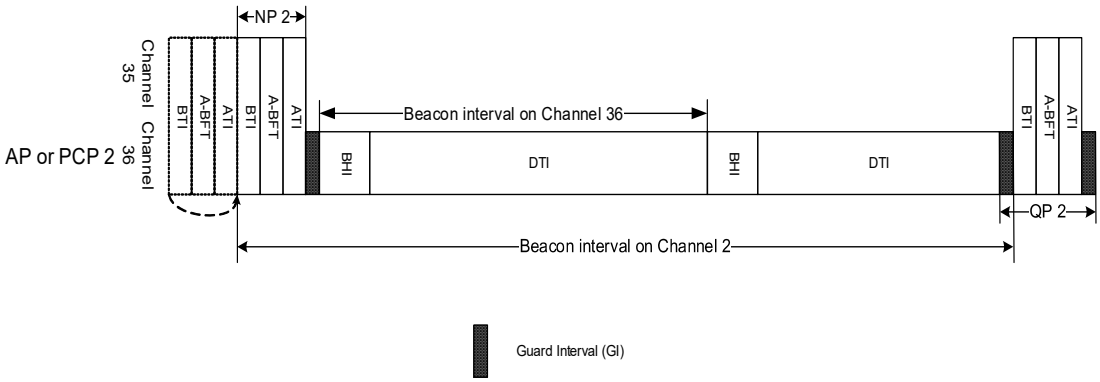

Figure 10-159—Moving TBTT by a neighboring AP or PCP on channel 2

10.63.3 Channel splitting of a 2.16 GHz channel

If a CDMG STA receives a DMG Beacon frame from a CDMG AP or PCP operating on a 2.16 GHz channel (e.g., channel 2), it may request the AP or PCP to shift its operating channel to one of the 1.08 GHz channels (e.g., channel 35) within its original 2.16 GHz channel by sending an Extended Channel Splitting Request frame (9.6.7.43) during the following ATI or it may associate with the infrastructure BSS or PBSS indicated by the BSSID field of the received DMG Beacon frame following the rules in 11.3 and subsequently send a Channel Splitting Request frame (9.6.28.4).

A non-AP and non-PCP CDMG STA within an infrastructure BSS or PBSS operating on a 2.16 GHz channel (e.g., channel 2) may send a Channel Splitting Request frame (9.6.28.4) during the ATI, SP, or CBAP, to request the AP or PCP to shift its operating channel to one of the 1.08 GHz channels (e.g., channel 35) within its original 2.16 GHz channel. If the existing CDMG BSS changed its operating channel to one of the 1.08 GHz channels (e.g., channel 35), the CDMG STA that sends the Channel Splitting Request frame may then operate a new BSS on the other adjacent 1.08 GHz channel (i.e., channel 36) within the 2.16 GHz channel (i.e., channel 2) as the role of AP or PCP.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The Channel Splitting Request frame or Extended Channel Splitting Request frame shall use the NP/BHI Duration field to indicate the required length of NP/BHI on a 2.16 GHz channel.

If a CDMG AP or PCP receives a Channel Splitting Request frame (9.6.28.4) or Extended Channel Splitting Request frame (9.6.7.43), the AP or PCP may follow the rules in 11.8.8.6 to switch its operating channel to a 1.08 GHz channel (e.g., channel 35) within its original 2.16 GHz channel (i.e., channel 2). If the AP or PCP switches the operating channel after receiving a Channel Splitting Request frame, it shall inform all its non-AP and non-PCP STAs of the DBC option it selects to operate on the 1.08 GHz channel after channel splitting, the target 1.08 GHz channel number to which it switches, and the starting time of the first beacon interval on 2.16 GHz channel when the channel splitting begins through the DBC Option subfield of the Dynamic Bandwidth Control element and the New Channel Number field and the Channel Switching Count field of the Channel Switch Announce element contained in the DMG Beacon and/or Announce frames. The AP or PCP shall also send a Channel Splitting Response frame (9.6.28.5) or Extended Channel Splitting Response frame (9.6.7.44) to announce the target 1.08 GHz channel number to which it switches and the starting time of the first beacon interval on 2.16 GHz channel when the channel splitting begins through the New Channel Number field and the Channel Switching Count field of the Channel Switch Announce element, the length of its beacon interval on 2.16 GHz channel after channel splitting through the Beacon Interval field, and the time offset of the scanning AP's or PCP's beacon interval relative to the existing AP's or PCP's beacon interval on 2.16 GHz channel and the lengths of NP/BHI durations for both APs or PCPs on 2.16 GHz channel through the TBTT Offset field, the NP/BHI Duration field, and the Adjacent NP/BHI Duration field of the Dynamic Bandwidth Control element to the CDMG STA indicated in the Source AID field in the received Channel Splitting Request frame or Extended Channel Splitting Request frame.

If a CDMG AP or PCP receives a Channel Splitting Request frame or Extended Channel Splitting Request frame but is not switching its operating channel, it may reply a Channel Splitting Response frame or an Extended Channel Splitting Response frame to reject the request.

If a CDMG STA sends a Channel Splitting Request frame or Extended Channel Splitting Request frame and then receives Channel Splitting Response frame or an Extended Channel Splitting Response frame with the Channel Splitting subfield set to 1, it shall follow the procedures described in 10.63.2.3 to maintain synchronization with the CDMG AP or PCP that sends the Channel Splitting Response frame or an Extended Channel Splitting Response frame when it starts a new BSS on the adjacent 1.08 GHz channel as the role of AP or PCP.

10.63.4 Channel expansion of a 1.08 GHz channel

A CDMG AP or PCP operating an infrastructure BSS or PBSS services on a 1.08 GHz channel (e.g., channel 35) may expand its operating bandwidth by switching to the 2.16 GHz channel (i.e., channel 2) encompassing its original operating channel without interruption to its BSS services.

If a CDMG AP or PCP operating an infrastructure BSS or PBSS on a 1.08 GHz channel (e.g., channel 35) transmits DMG Beacon frames on the 2.16 GHz channel containing a Dynamic Bandwidth Control element with the Channel Splitting subfield set to 1 and the Adjacent Channel Occupancy subfield set to 1, the AP or PCP may follow 11.8.8.6 to switch its operating channel to the 2.16 GHz channel (e.g., channel 2).

If a CDMG AP or PCP operating an infrastructure BSS or PBSS on a 1.08 GHz channel (e.g., channel 35) transmits DMG Beacon frames on the 2.16 GHz channel containing a Dynamic Bandwidth Control element with the Channel Splitting subfield set to 1 and the Adjacent Channel Occupancy subfield set to 0 but does not receive any DMG Beacon frame during the allocated NPs/BHI from another CDMG AP or PCP for a time period of 4×aMinBTIPeriod beacon intervals on the 2.16 GHz channel, the AP or PCP may follow 11.8.8.6 to switch its operating channel to the 2.16 GHz channel (e.g., channel 2).

If a CDMG AP or PCP operating an infrastructure BSS or PBSS on a 1.08 GHz channel (e.g., channel 35) transmits DMG Beacon frames on the 2.16 GHz channel containing a Dynamic Bandwidth Control element

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

with the Channel Splitting subfield set to 1 and the Adjacent Channel Occupancy subfield set to 0 and receives a DMG Beacon frame during a NP/BHI from another CDMG AP or PCP operating on the adjacent 1.08 GHz channel (e.g., channel 36) within a 2.16 GHz channel (i.e., channel 2), it shall not expand its operating bandwidth by switching to the 2.16 GHz channel.

If the CDMG AP of PCP is switching the operating channel, it shall transmit DMG Beacon frames during the scheduled NPs on the 2.16 GHz channel containing a Dynamic Bandwidth Control element with the Channel Splitting subfield equal to 1 and the Adjacent Channel Occupancy subfield equal to 0 until the intended channel switch time. The AP or PCP shall inform all the non-AP and non-PCP STAs in the BSS with the target 2.16 GHz channel number to which it switches and the starting time of the first beacon interval on the 2.16 GHz channel after the channel expansion through the New Channel Number field and the Channel Switching Count field of the Channel Switch Announce element contained in the DMG Beacon and/or Announce frames. Here, the starting time is set until to the end of a subsequent beacon interval on the 2.16 GHz channel. Note that the beacon interval length after channel expansion might be different with that before channel expansion.

Figure 10-160 (AP or PCP operating on channel 35 with independent beacon interval expanding the operating bandwidth to channel 2) and Figure 10-161 (AP or PCP operating on channel 35 without independent beacon interval expanding the operating bandwidth to channel 2) illustrate the examples that an AP or PCP (e.g., AP or PCP 1) operating on channel 35 switches to channel 2. In Figure 10-160 (AP or PCP operating on channel 35 with independent beacon interval expanding the operating bandwidth to channel 2), the AP or PCP 1 established an independent beacon interval on channel 35 while in Figure 10-161 (AP or PCP operating on channel 35 without independent beacon interval expanding the operating bandwidth to channel 2), the AP or PCP 1 does not.

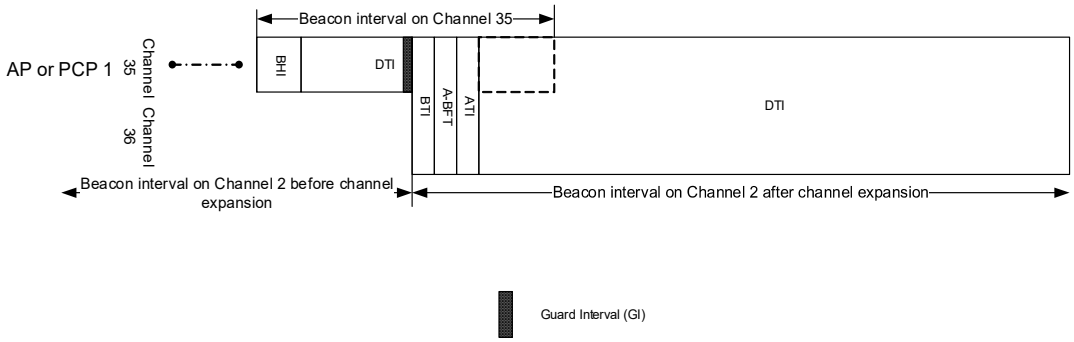

Figure 10-160—AP or PCP operating on channel 35 with independent beacon interval expanding the operating bandwidth to channel 2

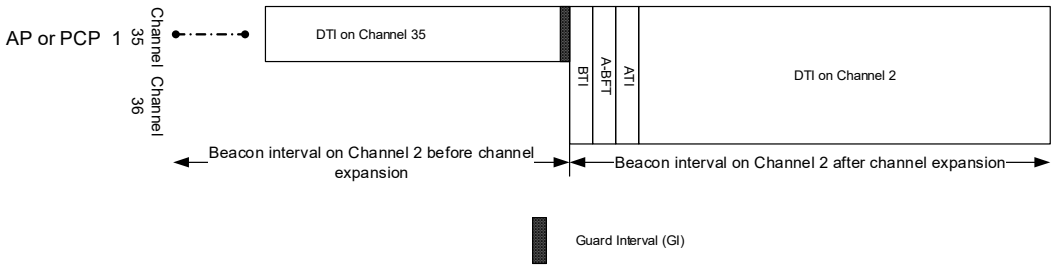

Figure 10-161—AP or PCP operating on channel 35 without independent beacon interval expanding the operating bandwidth to channel 2

10.63.5 Backward compatibility and interoperation

A CDMG AP or PCP operating an infrastructure BSS or PBSS shall provide interoperability to DMG STAs regardless of the BSS's operating channel. If a CDMG BSS is operating on a 2.16 GHz channel, the CDMG AP or PCP shall follow the channel access rules as described in 10.38 to provide services to non-AP and non-PCP DMG STAs.

A CDMG STA should not establish a 1.08 GHz BSS within a 2.16 GHz channel on which it received a DMG Beacon frame from a DMG AP or PCP. A CDMG AP or PCP operating on a 1.08 GHz channel shall transmit DMG Beacon frames on both the 1.08 GHz channel and the corresponding 2.16 GHz channel. A DMG STA can request to join a CDMG BSS. If the DMG STA successfully joins the CDMG BSS, the CDMG AP or PCP of the BSS shall schedule SPs and/or CBAPs for the DMG STA on the 2.16 GHz channel. The length of the scheduled SPs or CBAPs for DMG STAs on the 2.16 GHz channel is variable and may be up to the entire DTI. In other words, all STAs in the CDMG BSS operate on the 2.16 GHz channel if SPs and/or CBAPs are scheduled only on the 2.16 GHz channel during the DTI. The algorithm to schedule SPs or CBAPs for DMG STAs in a CDMG BSS is implementation dependent and beyond the scope of this standard but should aim to improve the network efficiency.

During an SP or a CBAP, the source and destination CDMG STAs operating on a 1.08 GHz channel in a CDMG BSS shall transmit an RTS frame and a DMG CTS or DMG DTS frame, respectively, on the corresponding 2.16 GHz channel after successfully transmitting and receiving an RTS frame and a DMG CTS or DMG DTS frame, respectively, on the 1.08 GHz channel if the 2.16 GHz channel is idle. Then the DMG STAs can set their NAVs by receiving the RTS or DMG CTS or DMG DTS frames transmitted on the 2.16 GHz channel by the CDMG STAs. After transmitting a CF-End frame to truncate an SP or TXOP on a 1.08 GHz channel within a 2.16 GHz channel, a CDMG STA shall also transmit a corresponding CF-End frame on the 2.16 GHz channel if it is idle.

If a CDMG infrastructure BSS or PBSS is operating on a 1.08 GHz channel, the CDMG AP or PCP shall follow the channel access rules in the BHI as described in 10.38 during the NPs/BHIs on the 2.16 GHz channel to admit non-AP and non-PCP DMG STAs into the BSS and provide scheduling information to DMG STAs. In the following medium time, the CDMG AP or PCP shall follow the rules in 10.38.6 to schedule the SPs or CBAPs for non-AP and non-PCP DMG STAs on the 2.16 GHz channel. If the CDMG AP or PCP establishes an independent beacon interval on its operating 1.08 GHz channel, it shall schedule SPs or CBAPs with non-AP and non-PCP DMG STAs as the source or destination STAs such that the scheduled SPs or CBAPs shall not be overlapped in time with the BHI periods on the 1.08 GHz channel. The CDMG AP or PCP may also schedule SPs or CBAPs on the 2.16 GHz channel for DMG STAs within the BSS to communicate with CDMG STAs within the BSS.

If a CDMG AP or PCP that is operating on a 1.08 GHz channel, with another CDMG BSS operating on the adjacent 1.08 GHz channel within a 2.16 GHz channel, the CDMG AP or PCP shall schedule only SPs or CBAPs with non-AP and non-PCP DMG STAs as the source or destination STAs in time periods that has been reported as unoccupied by the other CDMG AP or PCP through the Extended Schedule element in its DMG Beacon frames. The CDMG AP or PCP shall announce all its allocated SPs and CBAPs for the other CDMG AP or PCP, and the other CDMG AP or PCP can allocate SPs or CBAPs on the common 2.16 GHz channel in the unallocated time. In order to allocate time on the 2.16 GHz channel, the CMDG AP or PCP may also transmit a CDMG Allocation Request frame (9.6.28.6) during the ATI of the other AP's or PCP's NP/BHI on the 2.16 GHz channel to request for the available time for allocations on the 2.16 GHz channel. A CDMG AP or PCP that receives a CDMG Allocation Request frame from a CDMG AP or PCP operating on its adjacent 1.08 GHz channel shall reply with a CDMG Allocation Response frame (9.6.28.7) with an Extended Schedule element to indicate the schedule of all its allocations.

A CDMG AP or PCP that is operating on a 1.08 GHz channel, with another CDMG BSS operating on the adjacent 1.08 GHz channel within a 2.16 GHz channel, should appropriately reserve and schedule the available time for the AP or PCP operating on the adjacent 1.08 GHz channel and itself to allocate SPs or CBAPs on

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the 2.16 GHz channel, but the method to determine the reservation is implementation dependent. Four cases of backward compatibility and interoperation between DMG STAs and CDMG STAs are illustrated as follows.

A CDMG AP or PCP establishing an infrastructure BSS or PBSS on channel 35, with one or more beacon intervals starting on this channel, allows DMG STAs to join as non-AP and non-PCP STAs and allocates their SPs or CBAPs on channel 2 only, as shown in Figure 10-162 (SPs or CBAPs allocated for DMG STAs on channel 2 with beacon intervals starting on channel 35).

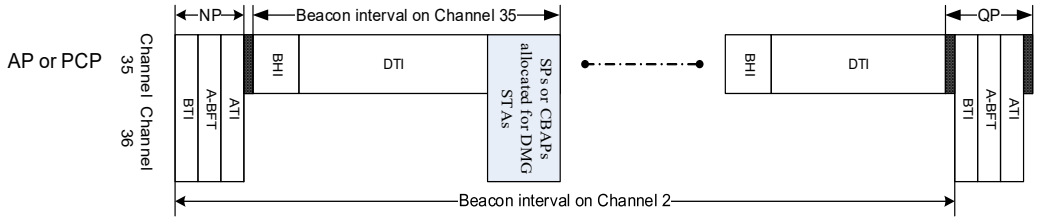

Figure 10-162—SPs or CBAPs allocated for DMG STAs on channel 2 with beacon intervals starting on channel 35

A CDMG AP or PCP establishing an infrastructure BSS or PBSS on channel 35, without starting a beacon interval on this channel, allows the DMG STAs to join as non-AP and non-PCP STAs and allocates their SPs or CBAPs on channel 2 only, as shown in Figure 10-163 (SPs or CBAPs allocated for DMG STAs on channel 2 without starting a beacon interval on channel 35).

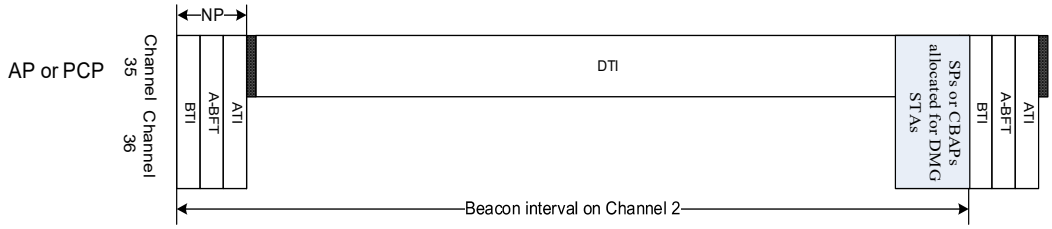

Figure 10-163—SPs or CBAPs allocated for DMG STAs on channel 2 without starting a beacon interval on channel 35

CDMG APs or PCPs establishing infrastructure BSSs or PBSSs on channels 35 and 36, respectively, with beacon intervals starting on this channel, allow the DMG STAs to join any of the BSSs or PBSSs as non-AP and non-PCP STAs and allocate their SPs or CBAPs on channel 2 only, as shown in Figure 10-164 (SPs or CBAPs allocated for DMG STAs on channel 2 with beacon intervals starting on channels 35 and 36).

CDMG APs or PCPs establishing infrastructure BSSs or PBSSs on channels 35 and 36, respectively, without starting a beacon interval on this channel, allow the DMG STAs to join any of the BSSs or PBSSs as non-AP and non-PCP STAs and allocate their SPs or CBAPs on channel 2 only, as shown in Figure 10-165 (SPs or CBAPs allocated for DMG STAs on channel 2 without starting a beacon interval on channels 35 and 36).

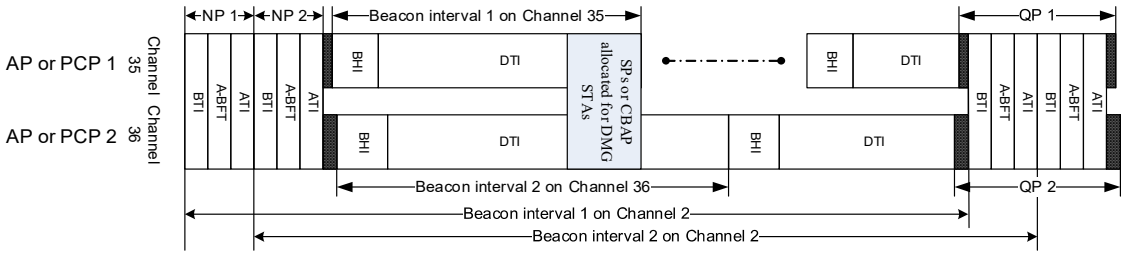

Figure 10-164—SPs or CBAPs allocated for DMG STAs on channel 2 with beacon intervals starting on channels 35 and 36

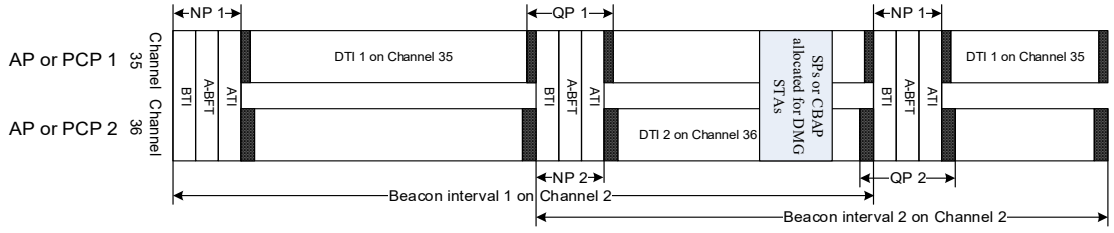

Figure 10-165—SPs or CBAPs allocated for DMG STAs on channel 2 without starting a beacon interval on channels 35 and 36

10.64 Addressing of GLK Data frame transmission

If a corresponding IEEE 802.1Q Bridge provides a station vector parameter that indicates a single general link, then the GLK STA shall transmit the MSDU using individually addressed MPDU(s) to the peer STA with one of the following methods:

— A frame with a three-address MAC header if the RA and the DA are equal and the transmitter is an AP.

— A frame with a four-address MAC header.

— A frame containing a Basic A-MSDU.

If a corresponding IEEE 802.1Q Bridge provides a station vector parameter that indicates multiple general links, then GLK transmission of the MSDU shall use one of the following methods:

— Transmit multiple individually addressed MPDUs to peer STAs.

— Transmit group addressed MPDU(s) using a SYNRA in a frame with a four-address MAC header with the following restrictions:

  — Shall not be sent by a non-GLK STA or non-AP STA.
  — Shall not address a STA that is in PS mode.
  — Shall not address a STA whose general link might pass through a relay.

A GLK AP may use any combination of these methods, such that each peer STA is addressed once. This also applies for each retry triggered by GLK-GCR, which shall use the same method for all transmission attempts.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The addressing of the frame with a four-address MAC header shall be as follows:

— Address 1 is the MAC address of the immediate destination STA (the receiver of the MPDU) or a SYNRA.
— Address 2 is the MAC address of the transmitter STA (the transmitter of the MPDU).
— Address 3 is the DA of the MSDU (the destination address of the MSDU), or BSSID for a Basic A-MSDU.
— Address 4 is the SA of the MSDU (the source address of the MSDU), or BSSID for a Basic A-MSDU.

The addressing of the frame with the three-address MAC header format containing a Basic A-MSDU shall be as follows:

— Address 1 is the MAC address of the immediate destination STA (the receiver of the MPDU).
— Address 2 is the MAC address of the transmitter STA (the transmitter of the MPDU).
— Address 3 is the BSSID.
— DA in A-MSDU subframe header is the DA of the MSDU (the destination address of the MSDU).
— SA in A-MSDU subframe header is the SA of the MSDU (the source address of the MSDU).

10.65 SYNRA filtering operation

A GLK infrastructure non-AP STA shall support reception of frames with a SYNRA as RA.

When a GLK non-AP STA receives an RA that is a group address in an MPDU from its associated GLK AP, if the SYNRA Type subfield does not represent a supported SYNRA type, or the From DS and To DS subfields in the Frame Control field are not both 1, then the non-AP STA shall discard the frame, and not use the frame for updating any scoreboard used for GLK-GCR block ack. All other group addressed Data frames received from the associated GLK AP shall be counted as received for the purposes of the scoreboard used for GLK-GCR block ack, even if discarded based on the subsequent SYNRA filtering, as described below.

For Basic SYNRA Control subfield, the frame shall be discarded if any of the following filter rules are satisfied:

— The AID of the STA falls within the range of AID values covered by the AID Bitmap subfield, and the bit representing its AID value is 0.
— The AID of the STA falls outside the range of AID values covered by the AID Bitmap subfield, and the Other AID subfield is 0.

10.67 EDMG phase hopping and open loop precoding operation

An EDMG STA supports phase hopping modulation defined in 28.6.9.3.8 (Phase hopping modulation) if the Phase Hopping Supported field in the STA's EDMG Capabilities element is 1. A phase hopping cbapable STA may transmit to a peer STA an EDMG OFDM mode SU PPDU with the TXVEXTOR parameter PHASE_HOPPING set to PH_APPLIED only if the peer STA has set the Phase Hopping Supported subfield in the peer STA's EDMG Capabilities element to 1 and the NUM_STS parameter in the TXVECTOR is set to 2.

An EDMG STA supports open loop precoding defined in 28.6.9.3.8 (Phase hopping modulation) if the Open Loop Precoding Supported subfield in the STA's EDMG Capabilities element is 1. An open loop precoding capable STA is also phase hopping capable. An open loop precoding capable STA may transmit to a peer STA an EDMG OFDM mode SU PPDU with the TXVECTOR parameter OPEN_LOOP_PC set to OL_APPLIED only if the peer STA has set the Open Loop Precoding Supported subfield in the peer STA's

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

EDMG Capabilities element to 1, and the NUM_ STS parameter in the TXVECTOR is set to 2 and the PHASE_HOPPING parameter in the TXVECTOR is set to PH_APPLIED.

10.68 EDMG AP or EDMG PCP distributed scheduling protocol operation

10.68.1 General

An EDMG PCP or EDMG AP may use the distributed scheduling protocol to improve spatial sharing and interference mitigation with other BSSs that use one or more of the same channels. An EDMG PCP or EDMG AP with dot11EDMGDistributedSchedulingProtocolActivated equal to true shall enable the distributed scheduling protocol by setting the Distributed Scheduling Enabled subfield to 1 in a transmitted EDMG Extended Schedule element. An EDMG PCP or EDMG AP shall follow the distributed scheduling protocol as described in this subclause during any beacon interval in which the PCP or AP transmits an EDMG Extended Schedule element with the Distributed Scheduling Enabled subfield equal to 1. In such cases, the PCP or AP is distributed scheduling enabled for this beacon interval.

10.68.2 Distributed scheduling initialization

When an EDMG PCP or EDMG AP first enables the distributed scheduling protocol, it shall listen for the maximum permitted beacon interval duration for DMG Beacons frames from neighboring PCPs or APs to determine the location (in terms of time and channel) and periodicity of their DMG Beacon frame transmissions as well as whether these PCPs or APs have the distributed scheduling protocol enabled.

10.68.3 Distributed scheduling protocol

While not engaged in communication within its BSS, a distributed scheduling enabled EDMG PCP or EDMG AP shall listen for DMG Beacon frames from neighboring PCPs or APs to determine their upcoming transmission schedules by parsing the Extended Schedule elements and EDMG Extended Schedule elements contained in received DMG Beacon frames. This may require listening on different channels, since neighbor PCPs or APs may operate in different primary channels.

If an AP or PCP determines that the BTI of a neighbor AP or PCP is overlapping or getting close to overlapping its own BTI in time, the AP or PCP may use the procedure in 11.30.2 (Spatial sharing and interference assessment) to move the TBTT of its BSS to remove or avoid the overlap. The procedure to determine when two BTIs are overlapping or drifting too close to overlapping in time is implementation dependent.

To distribute channel resources among PCPs or APs in the same coverage area, the PCP or AP shall determine how much of each beacon interval it can occupy on any given channel by dividing its beacon interval duration by the number of detected neighboring PCPs or APs that are using that channel. Thus, for each channel i that the PCP or AP is using, the PCP or AP shall not schedule allocations covering more than $1/(N_i + 1)$ of the beacon interval, where N_i is the number of detected neighboring PCPs or APs using channel i. Both the BHI and SPs shall count toward a PCP or AP's beacon interval usage, whereas CBAPs shall not count towards this total since CBAPs do not provide guaranteed transmissions.

When creating the Extended Schedule element and EDMG Extended Schedule elements, a distributed scheduling enabled PCP or AP shall do the following on each channel it is using. The PCP or AP shall randomly schedule its SPs over unoccupied time periods first. If after scheduling its SPs over unoccupied time periods the PCP or AP has not yet used its share of the channel, it may randomly schedule remaining SPs over time periods with no neighbor SPs. Finally, if after scheduling its SPs over time periods with no neighbor SPs the PCP or AP has not yet used its share of the channel, it may randomly schedule its remaining SPs over time periods with no SPs of distributed scheduling enabled PCPs or APs (i.e., the PCP

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

or AP is allowed to schedule over SPs of neighbors that have not enabled the distributed scheduling protocol).

A distributed scheduling enabled PCP or AP may schedule CBAPs anywhere in the DTI except during periods when the PCP or AP needs to listen for neighbor beacons. Allocated CBAPs should not traverse the start of SPs belonging to neighboring BSSs.

10.69 DMG segmentation and reassembly operation

10.69.1 General

A STA supports segmentation and reassembly if dot11SAROptionImplemented is true and, as a consequence, the Segmentation and Reassembly Support subfield in the STA's DMG Capabilities element is 1. A STA that supports segmentation and reassembly may employ this mechanism with a peer STA if the peer STA also supports segmentation and reassembly.

A DMG STA that supports segmentation and reassembly may segment large MSDUs received at the MAC SAP or A-MSDUs received at the A-MSDU aggregation function into MSDU or A-MSDU segments, respectively, that are transmitted into MPDUs (see 10.69.2 (Segmentation operation)). These MSDU or A-MSDU segments are reassembled at the recipient STA to recreate the original MSDU or A-MSDU (see 10.69.3 (Reassembly operation)). MSDU or A-MSDU segments shall be carried in individually addressed MPDUs.

The segmentation and reassembly mechanism allows a STA to receive at the MAC SAP an MSDU with a size that is optimal for an upper layer, or to aggregate MSDUs into A-MSDU, and that is not limited to the maximum transmission unit. The MSDU is delivered to the MAC SAP and the A-MSDU is delivered to the A-MSDU deaggregation function of the recipient STA through, respectively, MSDU or A-MSDU segments carried within MPDUs transmitted over the wireless link using the HT-Immediate BlockAck mechanism (see 10.25.6 (HT-immediate block ack extensions)). The recipient STA is responsible to reassemble the segmented MSDUs or A-MSDUs into their original size MSDU or A-MSDU and forward it to, respectively, the MAC SAP or A-MSDU deaggregation function. This mechanism allows sending a large MSDU or A-MSDU over the wireless link without the need for any upper layer fragmentation or segmentation processing. The maximum segmented MSDU or A-MSDU size is negotiated between communicating peers during SAR establishment (see 10.25.2 (Setup and modification of the block ack parameters)).

Segmentation and reassembly is established for a particular TID through the use of an ADDBA Request and ADDBA Response frame exchange that includes the SAR Configuration element. Segmentation and reassembly shall not be used under an unsolicited block ack agreement.

A pair of STAs that use segmentation and reassembly for a particular TID shall not employ MSDU fragmentation, as defined in 10.5 (MSDU, A-MSDU, and MMPDU defragmentation), for this TID.

A STA that supports segmentation and reassembly shall support reception of MPDUs carrying segments of different MSDUs or A-MSDU, plus any security encapsulation overhead, MAC header and FCS and to reassemble it back to the original MSDU or A-MSDU size.

Figure 10-166 (Example of segmentation and reassembly procedure) depicts an example of the transmission of MSDUs using the segmentation and reassembly procedure. In this example, the upper layer of the originator uses the MA-UNITDATA.request primitive to pass MSDUs to the MAC for delivery to the recipient. MAC level acknowledgments are not depicted in the figure. Delivered MPDUs reside in the recipient's reordering buffer. A MA-UNITDATA.indication primitive is used to deliver the complete MSDU to the recipient's upper layer. Moreover, in this example, MSDU $K - 1$ contains one segment delivered in the MPDU with $SN = N - 1$, which is successfully delivered to the recipient's reordering buffer

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

and then released to the recipient's upper layer. MSDU *K* comprises four MSDU segments that are transmitted to the recipient by MPDUs with $SN = N$, $N + 1$, $N + 2$, and $N + 3$. The first transmission attempt of MPDU $SN = N + 2$ fails and is retransmitted. The entire MSDU *K* is released to the recipient's upper layer upon arrival of all MSDU segments at the recipient's reordering buffer.

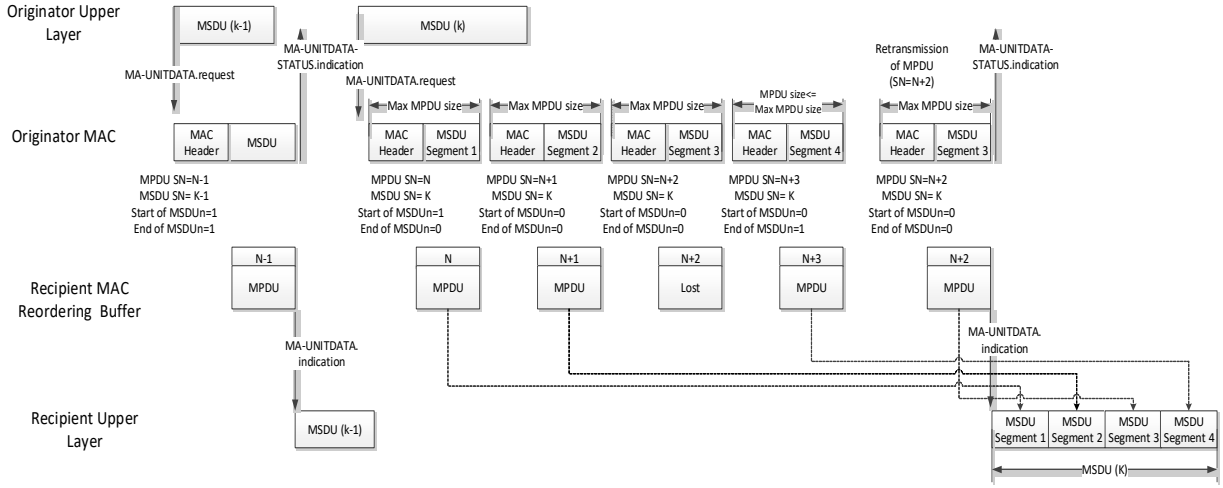

Figure 10-166—Example of segmentation and reassembly procedure

10.69.2 Segmentation operation

An MSDU or A-MSDU segment is carried within an MPDU. An MSDU or A-MSDU segment may comprise all or a portion of an MSDU or A-MSDU. Once an MSDU or A-MSDU segment is transmitted for the first time, its frame body content and length shall remain unchanged until it is successfully delivered to the recipient STA or the MSDU or A-MSDU is discarded.

An MPDU that contains the first segment of an MSDU or A-MSDU shall be assigned with a value of the Start of MSDU subfield equal to 1; otherwise, Start of MSDU shall be set to 0. An MPDU that contains the last segment of an MSDU or A-MSDU shall be assigned with a value of the End of MSDU subfield equal to 1; otherwise, the End of MSDU subfield shall be set to 0. An MPDU that has the End of MSDU subfield equal to 1 and the Start of MSDU subfield equal to 1 contains an entire single MSDU or A-MSDU. An MPDU that has the End of MSDU subfield equal to 0 and the Start of MSDU subfield equal to 1 shall have a size given by the maximum MPDU size as defined in 9.4.2.279. All MSDU Sequence Number and MPDU Sequence Number values assigned to an MPDU shall be set with continuously increasing sequential values.

10.69.3 Reassembly operation

A recipient STA reassembles an MSDU or A-MSDU comprising, respectively, one or more MSDU or A-MSDU segments according to the Start of MSDU, End of MSDU, MSDU Sequence Number, and MPDU Sequence Number indications of the MPDU of which the MSDU or A-MSDU segment is a part, as described in 10.25.6.6.2 (Operation for each received Data frame). The recipient MAC entity shall reassemble the MSDU or A-MSDU by concatenating, in increasing order of MPDU SN, the MSDU, or A-MSDU segments contained in the decrypted frame body of MPDUs with equal sequence numbers starting from the MPDU with Start of MSDU subfield equal to 1 and ending with the MPDU with End of MSDU subfield equal to 1.

The MA-UNITDATA.indication primitive is used by a recipient MAC to release a reassembled MSDU to its MAC SAP.

10.70 EDMG A-MPDU with multiple TIDs

10.70.1 General

A multi-TID A-MPDU is an A-MPDU that contains QoS Data frames where at least two of the QoS Data frames have different TID values.

An EDMG STA with dot11EDMGAMPDUwithMultipleTIDOptionImplemented set to true shall set the EDMG Multi-TID Aggregation Support subfield of the EDMG Capabilities element it transmits to a nonzero value. An EDMG STA with dot11EDMGAMPDUwithMultipleTIDOptionImplemented equal to false shall set the Multi-TID Aggregation Support subfield of the EDMG Capabilities element it transmits to zero.

An EDMG STA with dot11EDMGAMPDUwithMultipleTIDOptionImplemented set to true and that supports unsolicited block ack may set the Multi-TID Supported subfield of the Unsolicited Block Ack Extension Parameters field within the Unsolicited Block Ack Extension elements it transmits to 1. Otherwise, the EDMG STA shall set the Multi-TID Supported subfield to 0 to indicate that multi-TID is not supported under an unsolicited block ack agreement.

An EDMG STA may transmit a multi-TID A-MPDU to a peer EDMG STA if the EDMG STA has received from the peer STA an EDMG Capabilities element where the EDMG Multi-TID Aggregation Support subfield is nonzero. Otherwise, the EDMG STA shall not transmit a multi-TID A-MPDU to the peer EDMG STA.

An EDMG STA may transmit a multi-TID A-MPDU to a peer EDMG STA with a number of TIDs that does not exceed $MT + 1$, where MT is the value indicated in the EDMG Multi-TID Aggregation Support subfield within the EDMG Capabilities element transmitted by the peer EDMG STA.

An EDMG STA shall construct a multi-TID A-MPDU as defined in 9.6.35 and 10.12 (A-MPDU operation).

The sum of all block ack bitmap fields, negotiated as specified in 10.25.2 (Setup and modification of the block ack parameters), of all block ack agreements identified by TIDs included in a Multi-TID A-MPDU shall be less than or equal to 2048.

An EDMG STA may aggregate in a multi-TID A-MPDU QoS Data frames with multiple TIDs as defined in Table 9-662.

An EDMG STA may aggregate MPDUs from any TID in a multi-TID A-MPDU to be transmitted in an SP.

A multi-TID A-MPDU shall not be transmitted in a TXOP, except when the TXOP limit is nonzero for the AC that is used to gain access to the medium. This AC is defined as the primary AC. When the TXOP limit is nonzero, the STA may aggregate QoS Data frames from one or more TIDs in the A-MPDU under the following conditions:

- The A-MPDU is transmitted by the STA within the TXOP.
- The A-MPDU contains MPDUs with TIDs that correspond to the primary AC.
- When no more MPDUs can be aggregated in the A-MPDU from any of the TIDs that correspond to the primary AC, then the A-MPDU may additionally contain one or more MPDUs with TIDs that do not correspond to the primary AC if
  - The TIDs correspond to an AC that has a higher priority with respect to the primary AC.
  - The addition of these MPDUs does not cause the STA to exceed the current TXOP duration.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An EDMG Multi-TID BlockAck frame shall be used to acknowledge MPDUs in a received multi-TID A-MPDU. The rules for EDMG Multi-TID BlockAck are defined in 10.25.5 (Selection of BlockAck and BlockAckReq variants).

When a multi-TID A-MPDU is sent in response to an MPDU, received within an SU PPDU, with the RD Grant field set to 1 and the AC Constraint field set to 1 as specified in 10.29.3 (Rules for RD initiator), the lowest priority AC indicated in the MPDU that solicited the A-MPDU is defined as the primary AC. The recipient EDMG STA with dot11EDMGAMPDUwithMultipleTIDOptionImplemented equal to true may transmit a multi-TID A-MPDU and aggregate QoS Data frames from one or more TIDs in the A-MPDU under the following conditions:

- The A-MPDU is transmitted by the STA within the same TXOP or SP where the A-MPDU is solicited.
- The A-MPDU contains one or more MPDUs with any of the TIDs that correspond to the primary AC.
- When no more MPDUs can be aggregated in the A-MPDU from any of the TIDs that correspond to the primary AC, then the A-MPDU may additionally contain one or more MPDUs with TIDs that do not correspond to the primary AC if
  - The TIDs correspond to an AC that has a higher priority with respect to the primary AC.
  - The addition of these MPDUs does not cause the STA to exceed the current TXOP or SP duration.

10.70.2 Acknowledgment context in an EDMG Multi-TID BlockAck frame

A recipient of a multi-TID A-MPDU or of an EDMG MU-MIMO PPDU sets the Ack Type subfield in the EDMG Multi-TID BlockAck frame sent as a response depending on the acknowledgment context. The following acknowledgment contexts are defined as follows:

- **All Ack context:** If the originator has the EDMG All Ack Support subfield in its EDMG Capabilities element equal to 1, the recipient may set the Ack Type field to 2 to indicate the successful reception of all the MPDUs carried in the multi-TID A-MPDU. Otherwise, the recipient shall not set the Ack Type field to 2. The Multi-STA BlockAck frame shall contain only one Per-TID Info subfield field in the EDMG Multi-TID BlockAck frame.
- **BlockAck context:** The recipient shall set the Ack Type subfield to 0 and the TID field of each Per-TID Info subfield to a TID value of an MPDU contained in the multi-TID A-MPDU. The Block Ack Starting Sequence Control and Block Ack Bitmap fields shall be set according to 10.25.6 (HT-immediate block ack extensions) for each block ack agreement.
- **Ack context:** The recipient of an EDMG MU-MIMO PPDU shall set the Ack Type subfield to 1 and the TID field of the Per-TID Info subfield to the TID value of the MPDU with no block ack agreement contained in the EDMG MU-MIMO PPDU.

If all MPDUs in the multi-TID A-MPDU are received successfully, the recipient may follow the procedure described in the All Ack context. Otherwise, the recipient shall use the procedure defined in the BlockAck and Ack context.

11. MLME

11.1 Synchronization

11.1.1 General

STAs in a single infrastructure BSS, PBSS, or IBSS are synchronized to a common clock using the mechanisms defined in 11.1.

STAs in mesh BSSs use a synchronization method that is part of the extensible synchronization framework. The synchronization in an MBSS is described in 14.14.

A STA for which dot11OCBActivated is true is not a member of a BSS and, therefore, is not required to synchronize to a common clock or to use these mechanisms.

A timing synchronization function (TSF) keeps the timers for all STAs in the same BSS synchronized. All STAs in which dot11OCBActivated is false maintain a local TSF timer. STAs in which dot11OCBActivated is true may maintain a TSF timer for purposes other than synchronization.

A multi-band capable device (11.31) shall maintain a local TSF timer for each channel in which the STA operates.

A DMG STA that operates under TDD channel access (see 10.38.6.2.2) and that has the TDD Synchronization Mode subfield in the DMG Capabilities element equal to 1 shall maintain a local TSF timer as specified in 11.1.7.

11.1.2 Basic approach

11.1.2.1 TSF for an infrastructure BSS or a PBSS

In an infrastructure BSS or in a PBSS, the AP in the infrastructure BSS or the PCP in the PBSS shall be the timing master for the TSF. In a non-DMG and non-S1G BSS, the AP shall periodically transmit frames called *Beacon frames*. Instead of Beacon frames, an S1G AP shall periodically transmit S1G Beacon frames (as described in 11.1.3.10.1), which provide a similar function to the Beacon frame in a non-S1G BSS. Within an S1G BSS, the generation and/or reception of a Beacon frame and all references to it refer to that of the S1G Beacon frame. In a DMG BSS, the AP or PCP shall regularly transmit frames called *DMG Beacon frames* and *Announce frames*, which provide a similar function to the Beacon frame in a non-DMG BSS. Beacon, S1G Beacon, DMG Beacon, and Announce frames contain the value of the AP's or PCP's TSF timer in order to synchronize the TSF timers of other STAs in a BSS. A receiving STA shall accept the timing information in Beacon, S1G Beacon, DMG Beacon, and Announce frames sent from the AP or PCP servicing its BSS. An S1G STA that receives an S1G Beacon frame shall update its TSF timer according to the algorithm described in 11.1.3.10.3. If a STA's TSF timer is different from the timestamp in the received Beacon, S1G Beacon, DMG Beacon, or Announce frame, the receiving STA shall set its local TSF timer to the received timestamp value. A STA that receives a frame from its currently associated AP containing a Tetrapartial Timestamp or a Pentapartial Timestamp field may update its local TSF using the received portions of the AP's TSF timer contained in the received field, following the procedure described in 11.1.3.10.3.

In a non-DMG and non-S1G BSS, Beacon frames shall be generated for transmission by the AP once every dot11BeaconPeriod TUs. In an S1G BSS, the S1G AP shall generate S1G Beacon frames every dot11BeaconPeriod TUs; and if dot11ShortBeaconInterval is true, it shall additionally generate S1G Beacon frames every dot11ShortBeaconPeriod TUs as described in 11.1.3.10.1.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—The beacon interval, and hence the valid values of dot11BeaconPeriod, is constrained for APs in which dot11PublicHCCATXOPNegotiationActivated is true or dot11ProtectedHCCATXOPNegotiationActivated is true as specified in 11.26.4.1.

In a DMG infrastructure BSS, zero or more DMG Beacon frames shall be generated for transmission by the AP every dot11BeaconPeriod TUs (see 11.1.3.3). The AP shall transmit at least one DMG Beacon frame through each sector the AP chooses to use, within a time interval that is not longer than dot11BeaconPeriod × dot11MaxLostBeacons TUs. The determination of the sectors the AP chooses to use is implementation dependent, but should be determined in a way that allows unassociated STAs to discover the AP. The TXSS Span field in the DMG Beacon frame shall be set to a value that is less than or equal to dot11MaxLostBeacons.

NOTE 2—The AP can change the sectors it transmits DMG Beacon frames through, and the value of the TXSS Span field, depending on the number and location of associated STAs, and the AP's intention to be discoverable in various sectors.

In a PBSS, the value of the TSF timer is delivered to the STA by the DMG Beacon frames generated at each BTI and by the Announce frames generated during the ATI. In a PBSS, at TBTTs that do not start with a BTI, the PCP begins a beacon interval with an ATI sequence (see 11.1.3.3.2). The time interval in between two consecutive BTIs shall be an integer multiple of dot11BeaconPeriod TUs. A PCP or DMG AP shall set the Next Beacon subfield of the Beacon Interval Control field in the DMG Beacon frame to a value that indicates the number of beacon intervals following the current beacon interval during which the DMG Beacon frame will not be transmitted. The PCP shall transmit at least one DMG Beacon frame to each associated STA within a time interval that is not longer than dot11BeaconPeriod × dot11MaxLostBeacons TUs. The PCP shall transmit at least one DMG Beacon frame through each possible antenna configuration in a full-coverage set of antenna configurations within the number of beacon intervals specified within the most recently updated TXSS Span field.

11.1.2.2 TSF for an IBSS

The TSF in an IBSS is implemented via a distributed algorithm that is performed by all of the members of the BSS. Each STA in the IBSS shall transmit Beacon or S1G Beacon frames according to the algorithm described in this clause. Each IBSS STA shall adopt the TSF value received from any Beacon or S1G Beacon frame or probe response from the IBSS of which it is a member and which has a TSF value later than its own TSF timer. All Beacon frames transmitted in an S1G IBSS shall be S1G Beacon frames, and all references to the Beacon frame (generation and/or reception) in an S1G BSS refer to that of the S1G Beacon frame.

11.1.2.3 TSF for an MBSS

The TSF in an MBSS is provided by the MBSS's active synchronization method. A mesh STA shall initialize its TSF timer according to the MBSS's active synchronization method. The mesh STA shall periodically transmit Beacon frames that contain the value of its TSF timer to announce its local time reference. Mesh STAs receiving a Beacon frame use the timing information in the Beacon frame as specified by the MBSS's active synchronization method. See 14.14.2 for details.

11.1.3 Maintaining synchronization

11.1.3.1 General

Each STA shall maintain a TSF timer with modulus 2^{64} counting in increments of microseconds. Non-AP STAs that are not in a PBSS expect to receive Beacon frames at a nominal rate. In a non-DMG infrastructure BSS, the interval between Beacon frames is defined by dot11BeaconPeriod. In a DMG infrastructure BSS, the STAs expect to receive at least one DMG Beacon frame every dot11BeaconPeriod × dot11MaxLostBeacons TUs. Non-AP STAs in a PBSS expect to receive at least one DMG Beacon frame or one Announce frame every dot11BeaconPeriod × dot11MaxLostBeacons TUs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A non-DMG STA sending a Beacon, Timing Advertisement, or Probe Response frame, or a TIM frame with a TSF timestamp, shall set the frame's Timestamp field so that it equals the value of the STA's TSF timer at the time that the start of the data symbol containing the first bit of the Timestamp field appears at the transmit antenna connector. The Address 1 field of the Beacon or Timing Advertisement frame shall be set to the broadcast address.

A DMG STA sending a DMG Beacon, Announce, Timing Advertisement, or Probe Response frame, or a TIM frame with a TSF timestamp, shall set the frame's Timestamp field so that it equals the value of the STA's TSF timer at the time that the start of the data symbol containing the first bit of the frame appears at the transmit antenna connector. The Address 1 field of the Timing Advertisement frame shall be set to the broadcast address.

NOTE 1—In order that the value of the Timestamp field match the TSF value at the correct time, implementations need to compensate for delays along the transmit path, such as delays through the local PHY from the MAC-PHY interface to the transmit antenna connector.

NOTE 2—Unless otherwise specified, the rules that apply to Beacon frames might, depending on context, apply equivalently to DMG Beacon and S1G Beacon frames.

11.1.3.2 Beacon generation in non-DMG infrastructure networks

If the AP is a non-S1G AP, it shall define the timing for the entire BSS by transmitting Beacon frames according to dot11BeaconPeriod. If the AP is an S1G AP, it shall define the timing for the entire BSS by transmitting S1G Beacon frames according to dot11BeaconPeriod. This defines a series of TBTTs exactly dot11BeaconPeriod TUs apart. Time 0 is defined to be the TBTT when the first Beacon frame is expected to be sent and this beacon shall have the DTIM Count field of the TIM element set to 0. At each TBTT, the AP shall schedule a Beacon frame as the next frame for transmission according to the medium access rules specified in Clause 10.

NOTE 1—To achieve this requirement, the AP suspends any pending transmissions until the beacon has been transmitted. In the case of a DTIM beacon, the AP also suspends any pending individually addressed transmissions until any pending group addressed transmissions have been performed (see 11.2.3.4).

NOTE 2—When dot11MultiBSSIDImplemented is true, the DTIM Count field in the TIM element applies to the AP corresponding to the transmitted BSSID.

The beacon period is included in Beacon and Probe Response frames, and a STA shall adopt that beacon period when joining the BSS, i.e., the STA shall set dot11BeaconPeriod to that beacon period. A non-S1G AP shall not transmit S1G Beacon frames. The operation of an S1G AP is further defined in 11.1.3.10.1.

NOTE 3—Though the transmission of a Beacon frame might be delayed because of CSMA deferrals, subsequent Beacon frames are scheduled at the undelayed nominal beacon interval. This is shown in Figure 11-1.

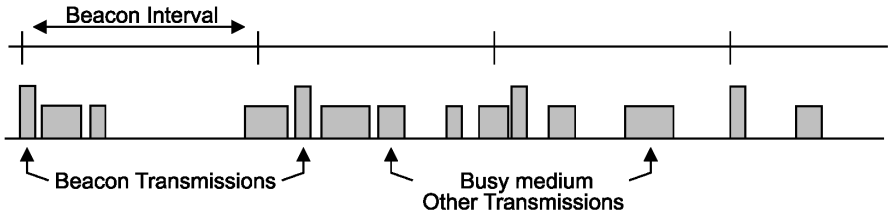

Figure 11-1—Beacon transmission on a busy network

The AP shall set the Short Slot Time subfield in the Capability Information field in the transmitted Beacon, Probe Response, Association Response, and Reassociation Response frames to indicate the currently used slot time value within its BSS (see 10.3.2.16).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An AP that supports Clause 18 operation shall use the long slot time unless the BSS consists only of the STAs that support short slot time. STAs indicate support for short slot time by setting the Short Slot Time subfield to 1 when transmitting Association Request and Reassociation Request frames. If the BSS consists of only STAs that support short slot time, short slot time may be used. APs indicate usage of the short slot time by setting the Short Slot Time subfield to 1 in all Beacon, Probe Response, Association Response, and Reassociation Response frame transmissions as described in 9.4.1.4.

If a STA that does not support short slot time associates with an AP that supports Clause 18 operation, and the AP is using short slot time, the AP shall use long slot time beginning at the first Beacon frame subsequent to the association of the long slot time STA.

NOTE 4—An AP that is using short slot time might reject association from a STA that does not support short slot time. See DENIED_NO_SHORT_SLOT_TIME_SUPPORT in 9.4.1.9.

An AP whose last transmitted values for the Tx STBC subfield and Rx STBC subfield of the HT Capability Information field of the HT Capabilities element are both nonzero may transmit an STBC Beacon frame and group addressed traffic using the basic STBC MCS, as defined in 10.6.3. An AP that transmits an STBC Beacon frame shall set the Dual Beacon field to 1 in transmitted HT Operation elements. A VHT AP shall set the Dual Beacon field to 0 in transmitted HT Operation elements. The STBC Beacon field shall be set to 1 to identify an STBC Beacon frame. The TBTT for the STBC Beacon frame shall be offset by half of a beacon interval from the TBTT of the non-STBC Beacon frame. Except for the setting of the STBC Beacon field, TIM element, and TSF field, all other fields inside the STBC Beacon frame shall be identical to the non-STBC Beacon frame.

The dual beacon mechanism is obsolete. Support for this mechanism might be removed in a later revision of the standard.

11.1.3.3 Beacon generation in a DMG infrastructure BSS and in a PBSS

11.1.3.3.1 General

A DMG STA acting as an AP or PCP follows the DMG channel access procedures (see 10.38) and the rules described in this subclause to transmit DMG Beacon frames.

Each DMG Beacon frame transmitted by a PCP and by a DMG AP shall have the Discovery Mode field within the DMG Beacon frame set to 0.

The Duration field of each transmitted DMG Beacon frame shall be set to the time remaining until the end of the current BTI.

A PCP and a DMG AP establish a series of target beacon transmission times (TBTTs) spaced dot11BeaconPeriod TUs apart. The period between two TBTTs is referred to as the *beacon interval*. The beacon interval length shall be no more than aMaxBIDuration. Time value zero of the TSF is defined to be a TBTT.

The length of the beacon interval is included in the DMG Beacon, Announce, and Probe Response frames, and a DMG STA shall adopt that beacon interval when joining the BSS.

A PCP and a DMG AP that move the TBTT (11.29.2) or change the beacon interval duration (11.29.3) shall reestablish the TBTT by resetting the TSF to 0 at the time the BSS parameter change takes effect in the BSS.

A PCP or an AP that schedules a TDD SP that occupies the entire beacon interval shall transmit DMG Beacons frames according to the procedure specified in 11.1.3.3.4 (Beacon generation under TDD channel access). In all other cases, the following procedures shall apply.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

At each BTI, a PCP and a DMG AP schedule DMG Beacon frames for transmission according to the procedure specified in 10.41.4. Subject to this constraint, the AP or PCP may delay the DMG Beacon frame transmission if the medium is determined by the CCA mechanism to be busy. When delaying a DMG Beacon frame transmission, the AP or PCP shall check that the BTI, A-BFT, and ATI do not overlap in time with pseudo-static SPs for which the AP or PCP is not the source DMG STA and, if AP or PCP clustering is in use, that the DMG Beacon frame transmission follows the additional rules described in 10.39.

An AP or PCP may transmit DMG Beacon frames through different antenna configurations during the BTI, but shall not transmit more than one DMG Beacon frame through the same antenna configuration during the BTI of any beacon interval. For any beacon interval that does not include a DMG Beacon frame transmission in the BTI, the AP shall begin the beacon interval with an ATI, and the PCP may begin the beacon interval with an ATI (11.2.7.3).

An EDMG AP or EDMG PCP can transmit a DMG Beacon frame using a quasi-omni antenna pattern as described in 10.41.4.

NOTE 1—The reception of a DMG Beacon frame transmitted using a quasi-omni antenna pattern indicates to the receiving STA a possibility of communicating with the AP or PCP (e.g., Probe Request, Probe Response) using a quasi-omni transmit antenna pattern.

When the DMG Beacon frame transmission is performed as multiple directional transmissions, an AP or PCP should change the sequence of directions through which a DMG Beacon frame is transmitted after it has transmitted a DMG Beacon frame through each direction in the current sequence of directions. When the ECAPC Policy Enforced field is equal to 1 in the DMG Beacon frame most recently transmitted by an AP or PCP, then

— When the AP or PCP transmits a DMG Beacon frame as multiple directional transmissions, the AP or PCP shall change the sequence of directions through which a DMG Beacon frame is transmitted after it has transmitted a DMG Beacon frame through each direction in the current sequence of directions.
— When the AP or PCP transmits a DMG Beacon frame as a single transmission, the AP or PCP shall randomly delay the transmission of the DMG Beacon frame by up to min(4×TXTIME(DMG Beacon), 1024×dot11MinBHIDuration) μs after the TBTT.

This is done to randomize and potentially minimize interference to/from the DMG Beacon. One such example is indicated in Figure 11-2 . If the sequence of directions is changed, the sequence of directions shall be pseudorandomly chosen from a sequence of directions covering the full set of directions available to an AP or PCP.

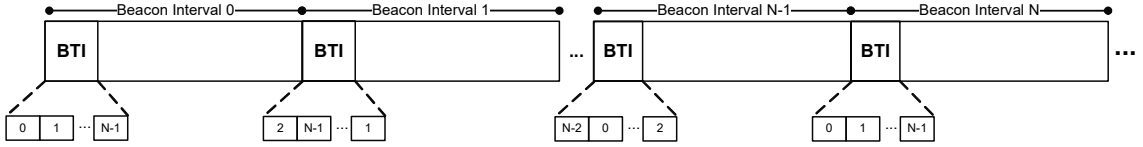

Figure 11-2—Example of DMG beacon transmission by an AP or PCP during the BTI

NOTE 2—An AP or PCP operating in a DMG BSS can transmit Announce frames during the ATI (10.38.3). An Announce frame can perform the function of a DMG Beacon frame, can be transmitted as an individually addressed frame directed to a STA, and can provide a much more spectrally efficient access than using a DMG Beacon frame.

A DMG STA that is an AP or a PCP shall include a DMG Operation element within a transmitted DMG Beacon frame if the CBAP Only field within the DMG Beacon frame is equal to 1. A DMG STA that is an AP or a PCP shall include a DMG Operation element within a transmitted DMG Beacon frame if the CBAP Only

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

field within the DMG Beacon frame is equal to 0 and the Extended Schedule element is included in the DMG Beacon frame. A DMG STA that is an AP or a PCP shall include a DMG Operation element within a transmitted Announce frame if the Extended Schedule element is included in the Announce frame.

11.1.3.3.2 Beacon generation in a PBSS

In a PBSS, every beacon interval shall start with a BTI or ATI, except in PCP power save (PPS) mode, where a PCP D-BI need not start with a BTI or ATI (see 11.2.7.3.3 (PCP operation with a wakeup schedule)).

A PCP that transmits a DMG Beacon frame with the CBAP Only field equal to 1 within a BTI shall include a BTI in any following beacon intervals until the completion of the TXSS of which the DMG Beacon frame is a part.

11.1.3.3.3 Beacon generation in a DMG infrastructure BSS

A DMG AP shall set dot11MaxLostBeacons to the value of the aMinBTIPeriod parameter.

11.1.3.3.4 Beacon generation under TDD channel access

If a TDD SP occupies the entire beacon interval, the DMG Beacon frame fields shall be set as follows:

— Next A-BFT subfield: set to a nonzero value
— Duration field: bits 0–13 set to 0, and bit 14 and bit 15 set to 1

11.1.3.4 DMG beacon generation before establishment of a BSS

A DMG STA can transmit DMG Beacon frames before establishment of a BSS to discover and perform beamforming during the A-BFT with another DMG STA so that the following frame exchanges between these STAs do not have to be done as a sector sweep (see 11.1.4.3.3).

A DMG STA that transmits DMG Beacon frames before establishment of a BSS shall set the Discovery Mode field in each transmitted DMG Beacon frame to 1 to indicates that the establishment of a BSS procedure defined in 11.1.4.4 has not been performed. In addition, the STA shall set the Next A-BFT field to 0.

Before establishment of a BSS, the spacing between TBTTs can change, and the time to the next TBTT is contained in each DMG Beacon frame transmitted at the last BTI. At each TBTT, the STA should generate a random value for the Beacon Interval field within the DMG Beacon frame from a uniform distribution between (10 TUs, 200 TUs), i.e., 10 TUs to 199 TUs. Every DMG Beacon frame transmission in the same BTI shall have the same value in its Beacon Interval field.

The TSF shall be set to 0 at the first TBTT for which the Discovery Mode field within the DMG Beacon frame is equal to 1. After that, the TSF shall be set to 0 at the TBTT of the beacon interval in which the STA changes the Beacon Interval field.

A STA shall transmit the first DMG Beacon frame of the next BTI at the time indicated by the start of the transmission of the first DMG Beacon frame within the last BTI and the Beacon Interval field contained in the DMG Beacon frame transmitted within the last BTI, unless the medium is determined by the CCA mechanism to be busy in which case the STA may delay the transmission of the first DMG Beacon frame transmission.

A STA that transmits a DMG Beacon frame with the Discovery Mode field equal to 1 may indicate the STA(s) that is allowed to respond in the A-BFT following the BTI where the DMG Beacon frame is transmitted. To do that, in the DMG Beacon frame the STA shall set the CC Present field to 1 and shall set the A-BFT Responder Address subfield to an individual address or to a group address of a group that includes the STA(s) that is allowed to respond in the A-BFT.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An EDMG STA can transmit a DMG Beacon using a quasi-omni antenna pattern as described in 10.41.4 (Beamforming in BTI).

NOTE—The reception of a DMG Beacon frame transmitted using a quasi-omni antenna pattern indicates to the receiving STA a possibility of communicating with the transmitting STA (e.g. Probe Request, Probe Response) using a quasi-omni transmit antenna pattern.

A DMG STA that is transmitting DMG Beacon frames with the Discovery Mode field equal to 1 should configure its receive antenna to a quasi-omni antenna pattern and stay in receiving state during portions of the DTI defined by the DMG Beacon frame transmissions. This enables the STA to receive frames transmitted by any STA that is covered by this antenna pattern.

A STA with dot11DMGOCBActivated equal to false that is transmitting DMG Beacon frames with the Discovery Mode field equal to 1 should cease transmitting these beacons when it has received a DMG Beacon frame from another STA, or when it has received acknowledgment of a transmitted Probe Response frame. If a BSS is not initialized as a result of the channel scanning, the STA can resume transmitting DMG Beacon frames with the Discovery Mode field equal to 1.

A STA with dot11DMGOCBActivated equal to true that is transmitting DMG Beacon frames with the Discovery Mode field equal to 1 may continue transmitting these beacons for discovery as described in 11.1.4.7 even if it has received a DMG Beacon frame from another STA.

The procedure of TBTT change described in the preceding paragraph is applicable for DMG Beacon frame generation before establishment of a BSS, whereas the procedures defined in 11.29.2 and 11.29.3 are used to change the DMG BSS parameters after an infrastructure BSS or PBSS has been established.

A STA shall set the Duration field of each transmitted DMG Beacon frame to the time remaining until the end of the current BTI.

11.1.3.5 Beacon generation in an IBSS

Beacon generation in an IBSS is distributed. The beacon period is included in Beacon, Announce, and Probe Response frames, and a STA shall adopt that beacon period when joining the IBSS. All members of the IBSS participate in beacon generation. Each STA shall maintain its own TSF timer that is used for dot11BeaconPeriod timing. The beacon interval within an IBSS is established by the STA at which the MLME-START.request primitive is performed to create the IBSS. An S1G STA in an IBSS has dot11ShortBeaconInterval set to false. This defines a series of TBTTs exactly dot11BeaconPeriod TUs apart. Time zero is defined to be a TBTT. At each TBTT the STA shall

a) Suspend the decrementing of the backoff counter for any pending transmission that is not a Beacon or DMG Beacon frame,
b) Calculate a random delay uniformly distributed in the range between zero and twice aCWmin × aSlotTime when the STA is a non-DMG STA, and between zero and the result of two multiplied by aCWminDMGIBSS multiplied by the duration of the STA's following BTI when the STA is a DMG STA,
c) Wait for the period of the random delay, decrementing the random delay timer using the same algorithm as for backoff, except that SIFS + aSlotTime should be used as the initial medium idle period within the backoff procedure. If the ATIM window in use within the IBSS is greater than 0 and the end of the ATIM window occurs before the random delay timer expires, cancel the remaining random delay and pending Beacon frame transmission and proceed to step f),
d) Cancel the remaining random delay and the pending Beacon frame transmission or BTI (DMG only), if a Beacon frame arrives from the IBSS of which the STA is a member before the random delay timer has expired,

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

e) Send a Beacon frame in a non-DMG BSS or DMG Beacon frame(s) in a DMG BSS if the random delay has expired and no Beacon frame in a non-DMG BSS or no DMG Beacon frame in a DMG BSS has arrived from the IBSS of which the STA is a member during the delay period,

f) If the ATIM window in use within the IBSS is greater than 0, then

   1) Resume decrementing the backoff counter for any pending transmission allowed inside the ATIM window and

   2) At the end of the ATIM window duration resume the backoff for any pending frames intended for transmission outside the ATIM window,

g) If the ATIM window in use within the IBSS is 0, then resume decrementing the backoff counter for any pending transmissions.

Figure 11-3 illustrates beacon transmission in an IBSS.

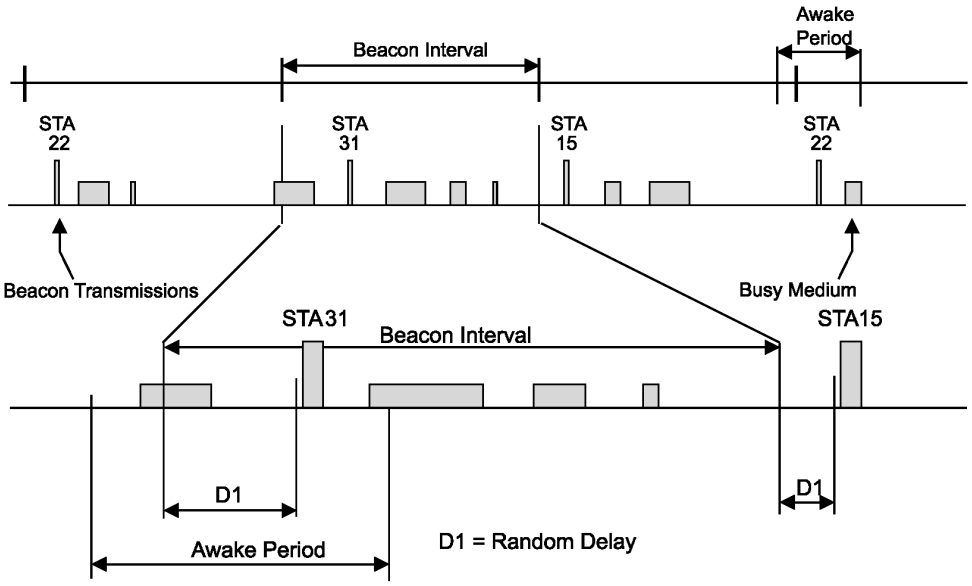

Figure 11-3—Beacon transmission in an IBSS

11.1.3.6 Beacon generation in an MBSS

Beacon generation in an MBSS is described in 14.14.3.1.

11.1.3.7 Beacon reception

STAs in an infrastructure network or PBSS shall use information in received Beacon frames, DMG Beacon frames, or Announce frames only if the BSSID field is equal to the MAC address currently in use by the STA contained in the AP of the BSS or to the MAC address currently in use by the PCP of the PBSS. A non-AP STA in an infrastructure BSS and a non-PCP STA in a PBSS that supports the Multiple BSSID capability shall use other information in received Beacon or DMG Beacon frames only if the BSSID field of the non-AP or non-PCP STA is equal to the MAC address currently in use by the STA contained in the AP or PCP, respectively, of the BSS corresponding to the transmitted BSSID or if the BSSID field of the non-AP or non-PCP STA is equal to one of the nontransmitted BSSIDs.

STAs in a non-DMG IBSS shall use information in any received Beacon frame for which the IBSS subfield of the Capability field is 1, the content of the SSID element is equal to the SSID of the IBSS, and the TSF value is later than the receiving STA's TSF timer. Use of this information is specified in 11.1.5.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

STAs in an MBSS shall use information in received Beacon frames as described in 14.14.3.2.

A non-AP STA in which dot11MultiBSSIDImplemented is true shall support frame filtering for up to two BSSIDs; one for the transmitted BSSID and one for the nontransmitted BSSID. The STA, when associated with a BSS corresponding to a nontransmitted BSSID, shall discard all Data and Management frames that use the transmitted BSSID as the transmitter address, except for Beacon, FILS Discovery, Probe Response, and TIM frames.

DMG IBSS STAs shall use other information in any received DMG Beacon (excluding those with the Discovery Mode field equal to 1) and Announce frames for which the BSS Type subfield is 1, the content of the SSID element is equal to the SSID of the IBSS, and the TSF value is later than the receiving STA's TSF timer. Use of this information is specified in 11.1.5.

A STA shall ignore the BSS Type field contained in a received DMG Beacon frame if the Discovery Mode field within the DMG Beacon frame is 1.

An active DMG STA operating in a BSS shall be ready to receive from its AP or PCP for a period of time of at least dot11MinBHIDuration following the TBTT or expected ATI start time as specified in the last Next DMG ATI element (9.4.2.134) transmitted by the AP or PCP.

An active DMG STA that is receive beamforming trained with the AP or PCP shall direct its receive antenna pattern toward the AP or PCP or use a quasi-omni antenna pattern during this time.

A non-PCP STA that receives a DMG Beacon frame from a PCP in which the PCP Association Ready field is 0 shall not transmit an Association Request frame addressed to the PCP that transmitted the received DMG Beacon frame. A non-PCP STA that receives a DMG Beacon frame from a PCP with the PCP Association Ready field set to 1 may transmit an Association Request frame addressed to the PCP that transmitted the received DMG Beacon frame.

11.1.3.8 Multiple BSSID procedure

11.1.3.8.1 General

A STA that supports the Multiple BSSID capability has dot11MultiBSSIDImplemented equal to true and shall set to 1 the Multiple BSSID field of the Extended Capabilities elements that it transmits. Support for the Multiple BSSID capability is mandatory for a FILS STA and non-AP HE STA. An AP that supports enhancements related to the discovery and advertisement of a nontransmitted BSSID shall set the Enhanced Multi-BSSID Advertisement Support bit in the Extended Capabilities element to 1 and is referred to as an EMA AP. A 6 GHz AP with dot11MultiBSSIDImplemented equal to true and advertising a partial list of nontransmitted BSSID profiles shall operate as an EMA AP. If an HE AP operating in the 2.4 GHz or 5 GHz bands has dot11MultiBSSIDImplemented equal to true, advertises a partial list of nontransmitted BSSID profiles, and intends a non-AP STA to discover the complete list of nontransmitted BSSID profiles, where a complete list of nontransmitted BSSID profile comprises only BSSIDs that are discoverable, then the HE AP shall operate as an EMA AP.

A nontransmitted BSSID is discoverable if the AP corresponding to the transmitted BSSID includes information of that BSSID in its Beacon and Probe Response frames (though not necessarily in every frame).

An AP with dot11MultiBSSIDImplemented equal to true shall set the Co-Hosted BSS subfield in HE Operation element that it transmits to 0.

The BSSID of the AP belonging to a multiple BSSID set is referred to as the transmitted BSSID if the AP includes the Multiple BSSID element in the Beacon frame that it transmits. In a multiple BSSID set, there shall not be more than one AP corresponding to the transmitted BSSID. The BSSID of an AP belonging to a

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

multiple BSSID set is a nontransmitted BSSID if the AP's BSS's BSSID is derived according to 9.4.2.44 and 9.4.2.72. Among all AP STAs in a multiple BSSID set, only the AP corresponding to the transmitted BSSID shall transmit a Beacon frame.

See 11.1.4.3.4 for the rules governing transmission of Probe Response frames in a multiple BSSID set.

11.1.3.8.2 Nontransmitted BSSID profile

A nontransmitted BSSID profile represents information about a particular nontransmitted BSSID. It consists of a set of elements that are carried in a single Nontransmitted BSSID Profile subelement, unless the subelement cannot fit in a single Multiple BSSID element. In this case, the nontransmitted BSSID profile is fragmented and is carried in more than one Nontransmitted BSSID Profile subelements across more than one Multiple BSSID element in the same frame. Each nontransmitted BSSID profile, at a minimum, shall include the elements that are mandatory for that BSS (i.e., Nontransmitted BSSID Capability element, SSID element, Multiple BSSID-Index element as described in 9.4.2.44). An example of Multiple BSSID element carrying one or more Nontransmitted BSSID Profile subelements is shown in Figure 11-4 . The figure also shows the order in which the elements are present within each Nontransmitted BSSID Profile subelement.

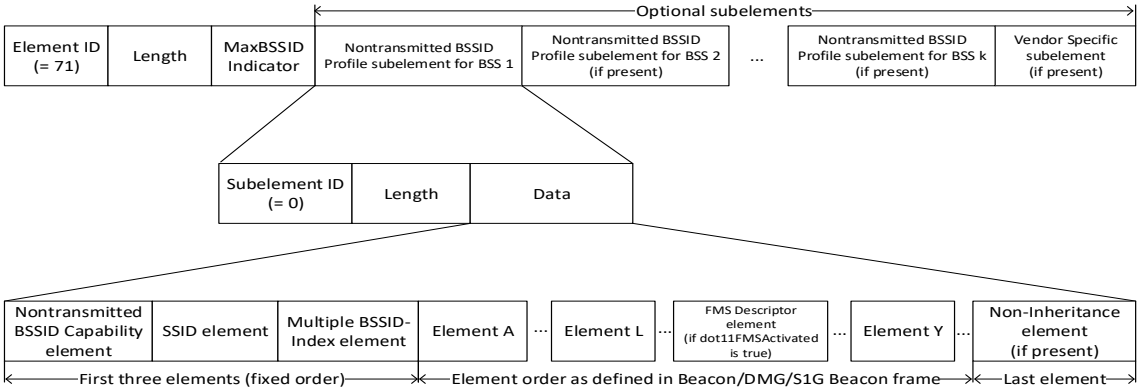

Figure 11-4—Example of Multiple BSSID element carrying Nontransmitted BSSID Profile subelements

A non-AP and non-PCP STA derives its nontransmitted BSSID according to 9.4.2.44 and 9.4.2.72.

An AP shall not carry a nontransmitted BSSID profile across multiple Multiple BSSID elements in a frame, unless the nontransmitted BSSID profile cannot fit in one multiple BSSID element due to the size limit of the multiple BSSID element.

If there is a need to fragment a nontransmitted BSSID profile across more than one Multiple BSSID element in a frame, an AP shall not fragment a nonfragmentable element in the profile across multiple Multiple BSSID elements, and it shall place the next element in that profile as the first element in the first Nontransmitted BSSID Profile subelement of the immediately following Multiple BSSID element. An AP shall not fragment a nontransmitted BSSID profile across two frames. If a frame carries multiple Multiple BSSID elements, the MaxBSSID Indicator field in all the Multiple BSSID elements shall carry the same value. In addition, an AP corresponding to the transmitted BSSID shall follow the procedures described in 10.28.13 if a nontransmitted

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

BSSID profile carries a fragmentable element whose Information field cannot fit the remaining length of the subelement.

A non-AP STA shall determine that a nontransmitted BSSID profile is fragmented if the next element in the frame is a Multiple BSSID element in which the first Nontransmitted BSSID Profile subelement does not contain the Nontransmitted BSSID Capability element as the first element. In addition, the non-AP STA shall follow the procedures described in 10.28.14 if the first element in the first Nontransmitted BSSID Profile subelement of the subsequent Multiple BSSID element is a Fragment element.

An example of a nontransmitted BSSID profile fragmented across two Multiple BSSID elements in a frame is shown in Figure 11-5 .

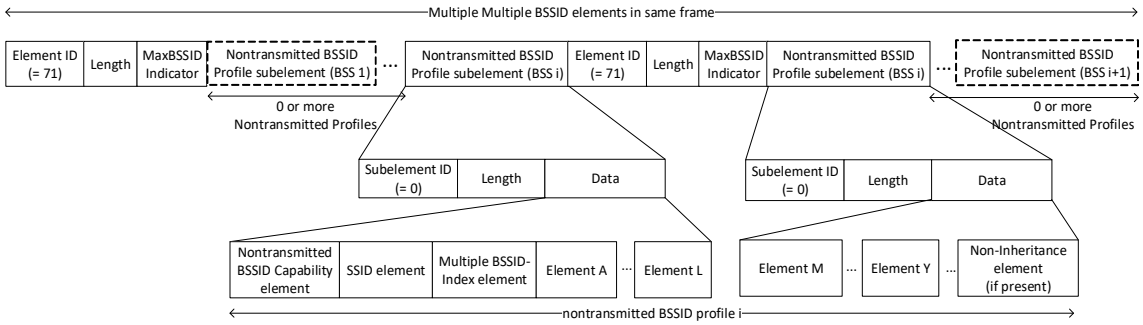

Figure 11-5—Example of nontransmitted BSSID profile fragmented across multiple Multiple BSSID elements

NOTE—As described in 9.4.3, the Length field of the Nontransmitted BSSID Profile subelement indicates the number of octets only in the Data field of the subelement.

11.1.3.8.3 Discovery of a nontransmitted BSSID profile

An AP or PCP may choose to include only a partial list of nontransmitted BSSID profiles in the Beacon frame, S1G Beacon frame, or DMG Beacon frame or to include different sets of nontransmitted BSSID profiles in different Beacon frames, S1G Beacon frames, or DMG Beacon frames. An AP corresponding to the transmitted BSSID may choose to include only a partial list of nontransmitted BSSID profiles in an unsolicited broadcast Probe Response frame or a Probe Response frame sent in response to a Probe Request frame with Address 3 field set to wildcard BSSID and SSID set to wildcard. An AP advertising a complete list of nontransmitted BSSID profiles shall set the Complete List Of NonTxBSSID Profiles field of Extended Capabilities element to 1.

If the most recent Beacon or Probe Response frame transmitted by the AP corresponding to the transmitted BSSID has the Complete List Of NonTxBSSID Profiles field equal to 0, then a non-AP STA with dot11MultiBSSIDImplemented equal to true should listen for additional Beacon frames from the AP or may send a Probe Request frame to the AP to gather information about one or more nontransmitted BSSIDs in the multiple BSSID set whose profile is not carried in the frame and that are of interest to the non-AP STA.

An EMA AP operating in the 2.4 GHz or 5 GHz band that transmits a Beacon or Probe Response frame carrying a partial list of nontransmitted BSSID profiles should include in the frame a Reduced Neighbor Report element carrying information for at least the nontransmitted BSSIDs that are not present in the Multiple BSSID element carried in that frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A 6 GHz-only EMA AP that transmits a Beacon or broadcast Probe Response frame carrying a partial list of nontransmitted BSSID profiles shall include a Reduced Neighbor Report element carrying information for at least the nontransmitted BSSIDs that are discoverable and not present in the Multiple BSSID element carried in that frame.

A 6 GHz-only EMA AP that transmits a FILS Discovery frame shall include a Reduced Neighbor Report element carrying information on all nontransmitted BSSIDs in the multiple BSSID set that are discoverable.

The EMA AP does this to aid the fast discovery of all nontransmitted BSSIDs in the multiple BSSID set that are discoverable.

NOTE 1—A FILS Discovery frame received from a 6 GHz AP with the Multiple BSSIDs Presence Indicator subfield equal to 1 and not carrying a Reduced Neighbor Report element implies that the AP's Beacon frame carries a complete list of nontransmitted BSSID profiles or that the information of the nontransmitted BSSID(s) is advertised in the 2.4 GHz or 5 GHz band by a colocated AP (see 11.53).

An EMA AP advertising a partial list of BSSID profiles, shall include the Multiple BSSID Configuration element (see 9.4.2.259) in its Beacon frame, S1G Beacon frame, or DMG Beacon frame and in any Probe Response frame it sends to indicate the configuration of the multiple BSSID set.

An AP shall set the BSSID Count field of the Multiple BSSID Configuration element to indicate the number of active BSSIDs in the multiple BSSID set, and shall set the Full Set Rx Periodicity field to indicate the number of beacons a scanning STA is required to receive in order to discover all the active nontransmitted BSSIDs in the set. An AP corresponding to the transmitted BSSID shall respond with a Probe Response frame carrying one or more Multiple BSSID elements that include, at a minimum, the profiles for the nontransmitted BSSIDs requested by the soliciting Probe Request frame.

NOTE 2—A nontransmitted BSSID profile is requested if, in the soliciting Probe Request frame, the SSID or BSSID matches the SSID or the BSSID, respectively, of the BSS corresponding to the nontransmitted BSSID.

An unassociated non-AP STA may transmit a Probe Request frame containing a Known BSSID element (see 9.4.2.260) and addressed to an EMA AP corresponding to the transmitted BSSID to gather information on nontransmitted BSSIDs that it has not discovered.

An EMA AP that transmits a Probe Response frame in response to a Probe Request frame containing a Known BSSID element shall, at a minimum, include the nontransmitted BSSID profiles not known to the requesting STA, unless the AP is unable to fit all of them in the response frame.

An EMA AP that includes a partial list of nontransmitted BSSID profiles in its Beacon frame, S1G Beacon frame, or DMG Beacon frame, shall advertise a particular nontransmitted BSSID profile in a repeating pattern such that the profile is present in at least one beacon in a sequence of beacons indicated by the Full Set Rx Periodicity field of the Multiple BSSID Configuration element, unless the membership of the multiple BSSID set changes. An EMA AP shall include a nontransmitted BSSID profile in the DTIM beacon of that BSS so that STAs associated to that AP can receive the profile (and any updates to the BSS configuration) without having to transition to awake state to receive additional beacons. An EMA AP shall select the DTIM interval for a nontransmitted BSSID as a multiple of the value carried in the Full Set Rx Periodicity field of the Multiple BSSID Configuration element. Annex AA provides several example configurations.

NOTE 3—An AP corresponding to a nontransmitted BSSID can transmit a group addressed frame to advertise any changes to its BSS operational parameters or termination of the BSS (i.e., transmission of a broadcast Disassociation frame) during the beacon interval that follows the profile's DTIM beacon.

NOTE 4—In order to aid fast discovery of nontransmitted BSSIDs via passive scanning, it is recommended that an AP select a small value for the Full Set Rx Periodicity field.

11.1.3.8.4 Inheritance of element values

When a nontransmitted BSSID profile is present in one or more Multiple BSSID elements carried in a Probe Response frame, Beacon frame, DMG Beacon frame, or S1G Beacon frame, the profile shall include all elements that are specific to the corresponding nontransmitted BSS. An element, identified by Element ID and Element ID Extension fields (if applicable), is considered to be specific to a BSS if any of the following conditions are satisfied:

— At least one element with the same Element ID and Extended Element ID fields (if applicable) is included in the frame that carries the Multiple BSSID element but the contents of the Information field are not the same for the nontransmitted BSSID.

— The nontransmitted BSSID satisfies the condition as specified in Table 9-69 for a Probe Response frame, Table 9-62 for a non-DMG non-S1G AP, Table 9-75 for a DMG AP, or Table 9-76 for a S1G AP for that element to be present while the transmitted BSSID does not satisfy the corresponding condition.

NOTE—For example, when there exists one or more Vendor Specific elements carried in a frame that includes the Multiple BSSID element containing a nontransmitted BSSID profile, and the contents of the Information field for at least one of the Vendor Specific elements are not the same as that of at least one Vendor Specific element that applies to the nontransmitted BSSID profile then, each Vendor Specific element that applies to the nontransmitted BSSID profile is included in the Nontransmitted BSSID Profile subelement.

When present in a nontransmitted BSSID profile, the elements appear in the same order as that in Table 9-69 for a Probe Response frame, Table 9-62 for a non-DMG non-S1G AP, Table 9-75 for a DMG AP, or Table 9-76 for a S1G AP.

If an element, identified by Element ID and Element ID Extension fields (if applicable), is carried in a Probe Response frame, Beacon frame, DMG Beacon frame, or S1G Beacon frame transmitted by an AP corresponding to the transmitted BSSID and there is no element having the same Element ID and Element ID Extension (if applicable) present in a nontransmitted BSSID profile, and the element is not listed in the Non-Inheritance element (if included) in the nontransmitted BSSID profile for that BSS, then a non-AP STA receiving the frame shall consider the element to be part of that nontransmitted BSSID's profile and the contents of the Information field shall apply to the nontransmitted BSSID. Otherwise, a non-AP STA receiving the frame shall not consider the element to be part of the nontransmitted BSSID profile.

Figure 11-6 illustrates the inheritance of elements in a nontransmitted BSSID profile. The example shows a Management frame (such as a Probe Response frame, Beacon frame, DMG Beacon frame, or S1G Beacon frame) transmitted by an AP corresponding to a transmitted BSSID. The frame includes several elements identified by their corresponding element ID (extension) values shown in parenthesis. The Multiple BSSID element (Element ID = 71) contains profiles for nontransmitted BSSID N and BSSID M. In this example, the Nontransmitted BSSID Profile subelement for BSSID N is expanded to show details of its contents and to illustrate the inheritance operation. Similar considerations apply for the Nontransmitted BSSID Profile subelement for BSSID M (not shown in the figure). In this example, the contents of the Information fields for Element ID's (Extension) B, C, and E are the same for BSSID N and as a result, these elements are not carried in the nontransmitted BSSID profile for BSSID N. In other words, BSSID N inherits these elements from the transmitted BSSID. BSSID N does not inherit element identified by element ID (extension) A and is listed in the Non-Inheritance element, which is the last element in the nontransmitted BSSID profile. Since the content of the Information field for the element identified by element ID (extension) F is not the same for BSSID N and the transmitted BSSID, the element is carried in the nontransmitted BSSID profile for BSSID N. Elements identified by element ID (extension) D and Y, are specific to the BSSID N and are carried in its profile. Since there is a difference between the Vendor Specific elements that apply to the transmitted BSSID and BSSID N, each Vendor Specific element that applies to BSSID N is carried in its nontransmitted BSSID profile, including Vendor Specific element carrying "Content (1)" which needs to be replicated in order to still apply to BSSID N.

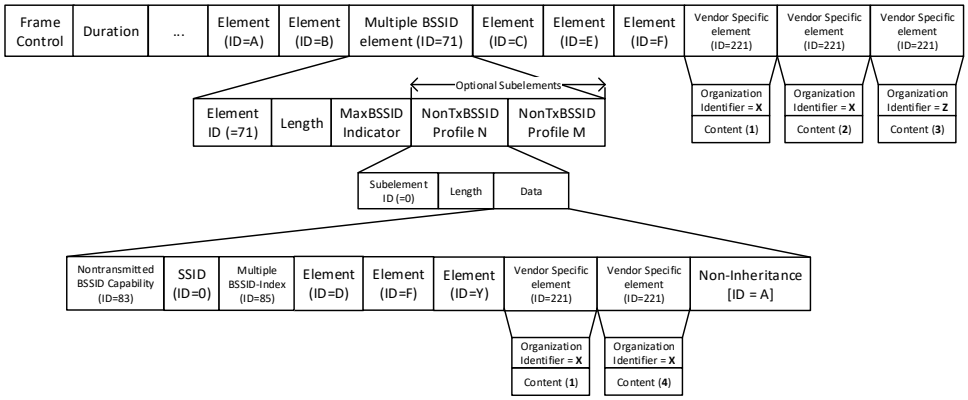

Figure 11-6—Example of inheritance in a nontransmitted BSSID profile

11.1.3.8.5 Traffic advertisement in a multiple BSSID set

The Partial Virtual Bitmap field of the TIM element carried in the Beacon, S1G Beacon, or TIM frame shall indicate the presence or absence of traffic to be delivered to all stations associated with an AP corresponding to a transmitted or nontransmitted BSSID. The first 2^n bits of the bitmap are reserved for the indication of group addressed frame for the transmitted and all nontransmitted BSSIDs (see 9.4.2.5.1). The Traffic Indicator field of the Bitmap Control field shall be set to 1 to indicate that one or more non-GCR-SP non-SYNRA group addressed frames, that are not to be delivered using group AID, are buffered at the AP corresponding to the transmitted BSSID. The field corresponding to a BSSID index (i.e., a bit position between 1 and $2^n - 1$ of the Partial Virtual Bitmap field matching the BSSID index of a nontransmitted BSSID) shall be set to 1 to indicate that one or more non-GCR-SP non-SYNRA group addressed frames, that are not to be delivered using group AID, are buffered at the AP corresponding to that nontransmitted BSSID. See Annex L for examples of traffic indication (including that for group addressed frames) in a multiple BSSID set. The AID space is shared by all BSSs and the lowest AID value that shall be assigned to a non-S1G STA is 2^n (see 9.4.2.5). The value of the 11 LSBs of the AID assigned to an S1G STA shall be greater than 2^n. The Encoded Blocks that contain these first 2^n AIDs (if any) shall precede the Encoded Blocks that contain AIDs for the S1G STAs in the S1G Partial Virtual Bitmap field of each page. Each BSS of the Multiple BSSID set may have a different DTIM interval, which is signaled in the DTIM Period and DTIM Count fields that are present in the Multiple BSSID-Index element carried in the nontransmitted BSSID profile for that BSS.

NOTE 1—The DTIM Count and DTIM Period fields of the TIM element carried in the Beacon frame transmitted by an AP corresponding to the transmitted BSSID indicates the DTIM interval for the transmitted BSSID.

An AP (which can correspond to either the transmitted BSSID or a nontransmitted BSSID) should advertise any change to the operational parameters that are specific to its BSS (such as, but not limited to, UORA parameter set or broadcast TWT parameter set) during the DTIM beacon for its BSS so that STAs associated to that AP can receive the changes in the DTIM beacon without having to transition to awake state for additional Beacon frames or S1G Beacon frames between the DTIM beacons.

For operational parameters that apply to all the BSSs in the multiple BSSID set and those that involve a countdown (such as, but not limited to, channel switch announcement or BSS color change announcement), the AP corresponding to the transmitted BSSID should select a countdown value such that the pertinent element(s) appears in at least one DTIM beacon of each AP in the set. This allows a STA associated with an AP in the set to receive the announcement during the DTIM beacon corresponding to its associated BSS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Based upon its knowledge of the capability of associated non-AP STAs to support the multiple BSSID capability, as indicated by the corresponding field in the Extended Capabilities element and the content of the traffic indication virtual bitmap, an AP shall encode the Partial Virtual Bitmap and the Bitmap Control fields of the TIM element using one of the three methods (Method A, Method B, or Method C) defined in 9.4.2.5.1. Specifically, a non-S1G AP shall use Method B if it determines that the bit for each associated non-AP STA in the traffic indication virtual bitmap that is reconstructed by each non-AP STA from the received TIM element encoded using Method B is set correctly. Otherwise, a non-S1G AP shall use Method A, and an S1G AP shall use Method C.

NOTE 2—If all the recipients of the TIM element are STAs that support the multiple BSSID capability (e.g., when the TIM element is carried in HE beacon, ER beacon, FILS Discovery frame, or OPS frame where all the addressees are non-AP HE STAs), the transmitting AP uses Method B to encode the Partial Virtual Bitmap and the Bitmap Control fields of the TIM element.

Multiple BSSID rate selection is defined in 10.6.9.

11.1.3.8.6 Multiple BSSID Index Adjustment Procedure

This subclause describes the procedure to adjust multiple BSSID index (see 9.4.2.72) values for each BSSID in a multiple BSSID set, which results in a different BSSID in the set taking over the role of the transmitted BSSID. The procedure helps to ensure that the multiple BSSID set continues to operate even if the AP corresponding to the transmitted BSSID no longer operates its BSS or intends to relinquish the role of being the transmitted BSSID.

An AP that supports the procedure described in this subclause sets the Multiple BSSID Role Switch Support subfield in the Extended Capabilities element to 1. A non-AP STA that supports computing the new BSSID index upon receiving the Index Adjustment Factor field sets the Multiple BSSID Role Switch Support subfield in the Extended Capabilities element to 1. When the multiple BSSID index adjustment procedure is being performed, the AP should transmit a Disassociation frame to each non-AP STA that does not support this procedure.

NOTE 1—If a non-AP STA that does not support this feature has indicated in its Extended Capabilities element that it supports BSS transition management, then the AP is recommended to indicate to that non-AP STA that disassociation is imminent and recommend other AP(s) for the non-AP STA to transition to (see 11.21.7.3).

When the multiple BSSID index adjustment procedure is being performed the AP corresponding to a transmitted BSSID in a multiple BSSID set shall include the Multiple BSSID Configuration element containing the Index Adjustment Factor field set to a nonzero value in the Beacon, DMG Beacon, S1G Beacon, and Probe Response frames that it transmits until the time when the adjustment occurs to inform non-AP STAs associated with all the APs in the multiple BSSID set that a BSSID index adjustment is imminent. The time advertised in the Index Adjustment TBTT Count field should be long enough that all non-AP STAs associated with the APs in the multiple BSSID set, including non-AP STAs in power save mode, have an opportunity to receive at least one Multiple BSSID Configuration element carrying the Index Adjustment Factor field before the adjustment takes effect.

At the TBTT indicated by the Index Adjustment TBTT Count field of the Multiple BSSID Configuration element, the AP transmitting the element and a non-AP STA receiving the element shall compute the updated index for each BSSID belonging to the multiple BSSID set as follows:

$$\text{New Index} = (\text{Old Index} + iaf) \bmod 2^n$$

where n is the MaxBSSID Indicator field in the Multiple BSSID element and *iaf* is the Index Adjustment Factor field in the Multiple BSSID Configuration element.

Following the index adjustment, the AP performs the following actions:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The BSSID whose new index value is 0 shall take on the role of the transmitted BSSID, and subsequent Beacon, DMG Beacon, S1G Beacon and Probe Response frames shall be transmitted by the AP corresponding to this BSSID.
— The BSSID Index field in a Multiple BSSID-Index element carried in a nontransmitted BSSID profile shall advertise the new index value for that nontransmitted BSSID.
— The elements included in a nontransmitted BSSID profile shall be based on inheritance with respect to the contents of the Management frame that carries the nontransmitted BSSID profile and that is transmitted by the new transmitted BSSID (also see 11.1.3.8.4).
— The indication of buffered group addressed frames via the bits in the TIM element shall be based on the new index value for each BSSID in the set (also see 11.1.3.8.5).

Following the index adjustment, a non-AP STA performs the following actions:

— The BSSID whose new index value is 0 shall be identified as the new transmitted BSSID.
— The BSSID index for the non-AP STA's associated AP shall be updated to the new index value and subsequently this value shall be used to determine buffered group address frames for its associated AP (also see 11.1.3.8.5).
— The inheritance as described in 11.1.3.8.4 shall be applied with respect to the new transmitted BSSID.

The value carried in the Index Adjustment Factor field shall be selected such that an index belonging to an active nontransmitted BSSID is updated to the value 0.

NOTE 2—The procedure makes no change to the BSSIDs (i.e., the MAC addresses) of the corresponding APs. Only the index within the multiple BSSID set is rotated such that a former nontransmitted BSSID with an updated index value of 0 takes on the role of the transmitted BSSID.

NOTE 3—For example, if we start with $n = 3$, transmitted BSSID = 8c-fd-0f-7f-1e-f5, and two nontransmitted BSSIDs BSSID(2) = 8c-fd-0f-7f-1e-f7 and BSSID(5) = 8c-fd-0f-7f-1e-f2, then an *iaf* of 6 converts the BSSID 8c-fd-0f-7f-1e-f7 to index $(2+6) \bmod 2^3=0$ as the transmitted BSSID, and the other BSSID index values are updated as BSSID($(5+6) \bmod 2^3=3$) = 8c-fd-0f-7f-1e-f2 and BSSID($(0+6) \bmod 2^3=6$) = 8c-fd-0f-7f-1e-f5 where the latter BSSID is converted into a nontransmitted BSSID.

11.1.3.9 TSF timer accuracy

A non-DMG STA's TSF timer shall be accurate to within ± 100 ppm. A DMG STA's TSF timer shall be accurate to within ± 20 ppm.

NOTE—The worst-case drift between two non-DMG STAs is, therefore, ± 200 ppm, and between two DMG STAs, ± 40 ppm.

Upon receiving a Beacon, a DMG Beacon, or an Announce frame for the BSS, as described in 11.1.3.7, a STA shall update its TSF timer according to the following algorithm

— Non-DMG STA: The received timestamp value shall be adjusted by adding an amount equal to the receiving STA's delay through its local PHY components plus the time since the first bit of the timestamp was received at the MAC/PHY interface.
— DMG STA: The received timestamp value shall be adjusted by adding an amount equal to the receiving STA's delay through its local PHY components plus the time since the last data symbol of the PHY header, excluding any guard interval, was received as indicated by the PHY-RXSTART.indication primitive.

In the case of an infrastructure BSS or a PBSS, the STA's TSF timer shall then be set to the adjusted value of the timestamp. In the case of an IBSS, the STA's TSF timer shall be set to the adjusted value of the received timestamp, if the adjusted value of the timestamp is later than the value of the STA's TSF timer.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When a STA is a member of a BSS with a nontransmitted BSSID, it shall use the TSF from the Beacon, S1G Beacon or DMG Beacon frame transmitted by the transmitted BSSID.

11.1.3.10 Maintaining synchronization using S1G Beacon frames

11.1.3.10.1 General S1G synchronization

An S1G AP schedules an S1G Beacon frame at intervals given by the dot11BeaconPeriod or dot11ShortBeaconPeriod as described in 11.1.2.1.

An S1G Beacon frame scheduled at TSBTT that is not a TBTT may include the elements from the minimum set of elements shown in Table 9-76. An S1G Beacon frame scheduled at TBTT shall include the S1G Beacon Compatibility element as the first optional element and may include all the other elements from the full set of elements shown in Table 9-76. Note that the S1G Beacon Compatibility element replaces the following fields of the Beacon frame body: Timestamp, Beacon Interval and Capability Information which are not included in an S1G Beacon frame. The S1G Beacon Compatibility element shall be generated no later than the Timestamp field of the S1G Beacon frame that carries the element and not earlier than 2^{31}– 1 μs. A STA can reconstruct the TSF timer at the AP by concatenating the TSF Completion field in the S1G Beacon Compatibility element with the Timestamp field in the S1G Beacon frame as described in 11.1.3.10.3.

11.1.3.10.2 Generation of S1G Beacon frames

In an infrastructure BSS, S1G Beacon frames shall be transmitted by an S1G AP. Each S1G STA in an IBSS shall transmit S1G Beacon frames. An AP with dot11ShortBeaconInterval equal to true shall further define the timing for the BSS by sending S1G Beacon frames according to the dot11ShortBeaconPeriod. The value for the dot11ShortBeaconPeriod shall be such that dot11BeaconPeriod = n×dot11ShortBeaconPeriod, where n is a positive integer. This defines a series of TSBTTs exactly dot11ShortBeaconPeriod TUs apart. If n is greater than 1, the Next TBTT field shall be present in S1G Beacon frames transmitted at TSBTT that is not a TBTT; otherwise, it shall not be present in S1G Beacon frames.

Time 0 is defined to be the TBTT or TSBTT when the first S1G Beacon frame is expected to be sent and this beacon shall have the DTIM Count field of the TIM element set to 0. At each TBTT or TSBTT, the AP shall schedule an S1G Beacon frame as the next frame for transmission. At each TBTT or TSBTT the AP should suspend the decrementing of the backoff counter for any pending non-beacon transmission and transmit the S1G Beacon frame according to the medium access rules specified in Clause 10.

NOTE—When dot11MultiBSSIDImplemented is true, the DTIM Count field in the TIM element applies to the AP corresponding to the transmitted BSSID.

The beacon period is included in S1G Beacon, Probe Response, and PV1 Probe Response frames, and a STA shall adopt that beacon period when joining the S1G BSS and S1G IBSS, i.e., the STA shall set its dot11BeaconPeriod to that beacon period. If dot11ShortBeaconInterval is equal to true, short beacon period included in the Short Beacon Interval element shall be carried in an S1G Beacon, Probe Response, and PV1 Probe Response frames. An S1G STA shall adopt that short beacon period when joining the S1G BSS or S1G IBSS, i.e., the STA shall set its dot11ShortBeaconInterval to true and its dot11ShortBeaconPeriod to that short beacon period.

11.1.3.10.3 TSF timer accuracy with S1G Beacon frame

Upon receiving an S1G Beacon frame with a valid FCS and BSSID, an S1G STA shall update its TSF timer according to the algorithm described below.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The received Timestamp value shall be adjusted by adding an amount equal to the receiving STA's delay through its local PHY components plus the time since the first bit of the Timestamp field was received at the MAC/PHY interface.

If the received S1G Beacon frame does not include an S1G Beacon Compatibility element:

— If the most significant bit (MSB) of the adjusted value of the received Timestamp is not equal to the MSB of the 4 least significant octets of the local TSF timer then the value of the 4 most significant octets of the TSF timer shall be adjusted to account for roll over as follows:
  — The value shall be increased by one unit (modulo 2^{32}) if LT > AT and LT > AT + 2^{31}
  — The value shall be decreased by one unit (modulo 2^{32}) if LT < AT and LT < AT – 2^{31}

  where AT is the adjusted value of the received Timestamp and LT is the value of the 4 least significant octets of the local TSF timer
— The 4 least significant octets of the STA's local TSF timer shall be set to the adjusted value of the Timestamp.

If the received S1G Beacon frame includes an S1G Beacon Compatibility element:

— The 4 least significant octets of the STA's TSF timer shall then be set to the adjusted value of the Timestamp.
— If the most significant bit of the adjusted value of the Timestamp is 0 and the TSF Rollover Flag field in the S1G Beacon Compatibility element is 1, then the 4 most significant octets of the TSF timer shall be adjusted to account for roll over (i.e., the value obtained from the TSF Completion field shall be increased by one unit (modulo 2^{32}). Otherwise, the 4 most significant octets of the TSF timer shall be set to the TSF Completion field in the S1G Beacon Compatibility element.

11.1.4 Acquiring synchronization, scanning

11.1.4.1 General

A STA shall operate in either a Passive Scanning mode or an Active Scanning mode depending on the current value of the ScanMode parameter of the MLME-SCAN.request primitive.

NOTE 1—Active scanning is restricted in some frequency bands and regulatory domains.

Upon receipt of the MLME-SCAN.request primitive, a STA shall perform scanning procedures according to the parameters given in the primitive. The SSID parameter indicates the SSID for which to scan. The SSID List parameter indicates one or more SSIDs for which to scan.

To become a member of a particular ESS using passive scanning, a STA shall scan for Beacon and DMG Beacon frames containing that ESS's SSID, returning all Beacon and DMG Beacon frames matching the desired SSID in the BSSDescriptionSet parameter of the corresponding MLME-SCAN.confirm primitive with the appropriate bits in the Capability Information field or DMG Capabilities field indicating whether the Beacon frame or DMG Beacon frame came from an infrastructure BSS, PBSS, or IBSS. If dot11RMMeasurementPilotActivated is greater than 1, the STA shall additionally scan for Measurement Pilot frames, returning in the BSSDescriptionFromMeasurementPilotSet parameter all Measurement Pilot frames that equal the requested BSSID of the corresponding MLME-SCAN.request primitive and are not already members of the BSSDescriptionSet. A FILS STA shall additionally scan for FILS Discovery frames, returning in the BSSDescriptionFromFDSet parameter all FILS Discovery frames of the scanned ESSs. The STA is not required to return a BSSDescriptionFromFDSet parameter for any BSS that is already a member of the BSSDescriptionSet.

To actively scan, the STA shall transmit Probe Request frames containing a wildcard SSID (see 9.4.2.2), the desired SSID or one or more SSID List elements, but a DMG STA might also have to transmit DMG Beacon

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

frames or perform beamforming training prior to the transmission of Probe Request frames. When the SSID List element is present in the Probe Request frame, one or more of the SSID elements may include a wildcard SSID (see 9.4.2.2). The exact procedure for determining the SSID or SSID List values in the MLME-SCAN.request primitive is not specified in this standard. When a STA scans for a BSS whose AP does not support the SSID List element, or for a BSS for which AP support of the SSID List element is unknown, the SSID element with an SSID or wildcard SSID shall be included in the MLME-SCAN.request primitive. During FILS scanning, the scanning STA may optimize the scanning process by using intermediate results, including the Reduced Neighbor Report element. Details of how to optimize scanning is out of scope of this standard. An MLME-SCAN.confirm primitive is issued each time that a BSS matching the selection criteria in the MLME-SCAN.request primitive is discovered when the ReportingOption parameter in the MLME-SCAN.request primitive is present and is equal to IMMEDIATE. An MLME-SCAN.confirm primitive is issued each time that the scanning STA has completed the scanning of a channel when the value of the ReportingOption parameter in the MLME-SCAN.request primitive is present and is equal to CHANNEL_SPECIFIC.

NOTE 2—MLME-SCAN.request primitives and resulting Probe Request frames might include a Request element or Extended Request element(s) that can be used to request radio measurement information from the scanned BSSs. Requested radio measurement information from the scanned BSSs is included in the Probe Response frames and in the MLME-SCAN.confirm primitive.

Upon completion of scanning, an MLME-SCAN.confirm primitive is issued by the MLME indicating all of the BSS information received.

In DMG BSSs, the Active Scan procedure (11.1.4.3) can be used for device discovery prior to initializing or joining a BSS.

Upon receipt of an MLME-JOIN.request primitive, the nonmesh STA shall use the synchronization procedure described in 11.1.4.5. The MLME-JOIN.request primitive is not used to start synchronization in an MBSS. The synchronization in an MBSS is described in 14.14.

Upon receipt of an MLME-SCAN.request primitive with the SSID parameter equal to the wildcard SSID, the STA shall passively scan for any Beacon, DMG Beacon, FILS Discovery, Measurement Pilot frames, or Probe Response frames containing Address 1 field equal to the broadcast address, or transmit Probe Request or DMG Beacon frames containing the wildcard SSID, as appropriate depending upon the value of ScanMode.

If a STA’s scanning does not result in finding a BSS with the target SSID and of the target type, or does not result in finding any BSS, the STA may start an IBSS upon receipt of the MLME-START.request primitive.

NOTE 3—Starting an IBSS is restricted in some frequency bands and regulatory domains.

When scanning MBSSs, the STA shall process the procedures described in 14.3.

When a STA starts a BSS, that STA shall determine the BSSID of the BSS. If the BSSType indicates an infrastructure BSS, then the STA shall start an infrastructure BSS and the BSSID shall be equal to the STA’s dot11StationID. If the BSSType indicates a PBSS, then the STA shall start a PBSS. For both the infrastructure BSS and the PBSS, the value of the BSSID shall remain unchanged, even if dot11StationID is changed after the completion of the MLME-START.request primitive. If the BSSType indicates an IBSS, the STA shall start an IBSS, and the BSSID shall be an individual locally administered MAC address as defined in Clause 8 of IEEE Std 802-2014. The remaining 46 bits of that MAC address shall be a number selected in a manner that minimizes the probability of STAs generating the same number, even when those STAs are subjected to the same initial conditions. The value of the SSID parameter shall be used as the SSID of the new BSS.

NOTE 4—It is important that designers recognize the need for statistical independence of the random number streams between STAs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Upon receipt of the MLME-DMG-OCB-START.request primitive, a DMG STA with dot11DMGOCBActivated equal to true shall start a discovery procedure outside the context of a BSS as described in 11.1.4.7 and start operation outside the context of a BSS as described in 31.3.

11.1.4.2 Passive scanning

11.1.4.2.1 Passive scanning for non-DMG STAs

If the ScanType parameter indicates a passive scan, the STA shall listen to each channel scanned for no longer than a maximum duration defined by the MaxChannelTime parameter.

11.1.4.2.2 Passive scanning for DMG STAs

Upon receipt of the MLME-SCAN.request primitive with the ScanType parameter set to Passive, a DMG STA shall passively scan for transmissions on each channel specified within the ChannelList parameter of the MLME-SCAN.request primitive. The channel traversal order during passive scanning is implementation specific.

That is, the STA shall be in the receive state scanning for a period of time in a channel no less than MinChannelTime and return information on all DMG Beacon frames received matching a particular BSSID or SSID parameters specified in the MLME-SCAN.request primitive. If no DMG beacon scan parameters are specified in the request, then the STA shall return information on all received DMG Beacon frames.

If at any time during the scan the STA detects a frame that is not a DMG Beacon frame, the STA shall continue to scan the current channel until the scanning timer expires. After scanning one channel, the STA shall initiate scanning in another channel if at least one channel within the ChannelList parameter has not yet been scanned.

When the STA has completed scanning all indicated channels, it returns the scan results via the MLME-SCAN.confirm primitive.

NOTE—Unlike a DMG STA that is actively scanning and that is not a member of PBSS (see 11.1.4.3.3), a DMG STA that is passively scanning does not respond to Probe Request frames (see 11.1.4.3.4).

11.1.4.3 Active scanning and probing procedures

11.1.4.3.1 Introduction

Active scanning involves the generation of Probe Request frames and the subsequent processing of received Probe Response frames. The details of the active scanning procedures are as specified in the following subclauses.

11.1.4.3.2 Active scanning procedure for a non-DMG STA

Upon receipt of the MLME-SCAN.request primitive with ScanType parameter indicating an active scan, a STA shall use the following procedure.

For each channel to be scanned:

a) Wait until the ProbeDelay time has expired or a PHY-RXSTART.indication primitive has been received.
b) If the STA is a FILS STA or a 6 GHz HE STA, set the FILSProbeTimer to 0 and starts the FILSProbeTimer. While the FILSProbeTimer is less than dot11FILSProbeDelay, the STA may skip a Probe Request frame transmission and proceed to step g) after setting the ActiveScanningTimer to 0 and starting the ActiveScanningTimer, if one of the following conditions matches:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

1) The STA receives a broadcast Probe Request frame that the SME considers to be suitable to discover a candidate AP for association.
2) The STA receives one or more of Probe Response, Beacon, Measurement Pilot, or FILS Discovery frame that identify an AP that the SME considers a suitable candidate for association.
3) The STA successfully sent a Probe Request frame by following the UORA procedure as defined in 26.5.4).

NOTE—How an SME considers a Probe Request frame or AP suitable is outside the scope of this standard.

c) Perform the basic access procedure as defined in 10.3.4.2. While waiting for access to WM, the STA may send one or more Probe Request frames by following the UORA procedure and proceed to step g). Send a Probe Request frame to the broadcast address. The Probe Request frame is sent with the SSID and BSSID from the received MLME-SCAN.request primitive. If dot11SSIDListActivated is true and the SSID List parameter is present in the MLME-SCAN.request primitive, then one or more SSID List elements should be present in the Probe Request frame, indicating all SSIDs in the SSID List parameter if possible.
d) When dot11SSIDListActivated is true and either or both of the SSID List and Short SSID List parameters are present in the MLME-SCAN. request primitive, send zero or more Probe Request frames to the broadcast address, each with one or more SSIDs indicated in the SSID List and/or Short SSID List parameters and the BSSID from the MLME-SCAN.request primitive. A Probe Request frame that contains a Short SSID List element shall have the SSID field of the SSID element set to the SSID of a known AP or set to the one-octet value 128 if the STA does not know any SSID. These additional Probe Request frames [following step c)] should only carry SSIDs not indicated in the step c) Probe Request frame. The basic access procedure (10.3.4.2) is performed prior to each Probe Request frame transmission.
e) Initialize the ActiveScanningTimer to 0 and start the ActiveScanningTimer.
f) If a PHY-CCA.indication(BUSY) primitive is not received before the ActiveScanningTimer reaches MinChannelTime, then proceed to step k).
g) If the STA is a non-FILS STA, receive all Probe Response and Beacon frames while the ActiveScanningTimer is less than MaxChannelTime.
h) If the STA is a FILS STA and while the ActiveScanningTimer is less than MaxChannelTime:
    1) Receive Probe Response, FILS Discovery, and Beacon frames regardless of the receiver address. Process any received FILS Discovery, Probe Response, and Beacon frames.
    2) If the ReportingOption parameter of the MLME-SCAN.request primitive is IMMEDIATE, and the scanning FILS STA detects a BSS whose MLME-SCAN.confirm primitive has not been issued during the ongoing scan, then an MLME-SCAN.confirm primitive with the ResultCode equal to INTERMEDIATE_SCAN_RESULT and one or more of BSSDescriptionSet, BSSDescriptionFromFDSet, or BSSDescriptionFromMeasurementPilotSet containing information of the detected BSS is immediately issued.
i) If the ReportingOption parameter of the MLME-SCAN.request primitive is CHANNEL_SPECIFIC, do the following:
    1) If the ActiveScanningTimer has not reached MaxChannelTime, wait until the ActiveScanningTimer reaches the MaxChannelTime and then proceed to item 2); otherwise, proceed directly to item 2).
    2) Issue an MLME-SCAN.confirm primitive, with the ResultCode equal to INTERMEDIATE_SCAN_RESULT and one BSSDescriptionSet, BSSDescriptionFromFDSet, or BSSDescriptionFromMeasurementPilotSet containing information of all BSSs that have been discovered from the scanned channel.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

j) Process all Probe Response frames received until the timer reaches MaxChannelTime, constructing BSSDescriptions corresponding to the probe responses that match the criteria specified in the MLME-SCAN.request primitive.

k) Set the NAV to 0 and scan the next channel.

l) When all channels in the ChannelList have been scanned, and the ReportingOption parameter of the MLME-SCAN.request primitive is AT_END or not present, the MLME shall issue an MLME-SCAN.confirm primitive with one or more of the BSSDescriptionSet, BSSDescriptionFromFDSet, or BSSDescriptionFromMeasurementPilotSet containing all of the information gathered during the scan.

See Figure 11-7 and Figure 11-8 .

If the MLME receives an MLME-SCAN-STOP.request primitive, the STA shall stop scanning. The STA should discard any Probe Request frame queued for transmission. If the STA is transmitting a Probe Request frame, the STA shall complete the transmission of the Probe Request frame. The STA shall not continue the active scanning process on unscanned channels listed in the ChannelList parameter of the MLME-SCAN.request primitive. If the ReportingOption parameter of the MLME-SCAN.request primitive is AT_END or not present, then the MLME shall issue an MLME-SCAN.confirm primitive with the ResultCode set to SUCCESS and with one or more of BSSDescriptionSet, BSSDescriptionFromFDSet, or BSSDescriptionFromMeasurementPilotSet containing all of the information gathered during the scan.

A FILS STA shall indicate its MaxChannelTime in the Max Channel Time field of the FILS Request Parameters element of the Probe Request frame to prevent the responding STA from transmitting the Probe Response frame after the time indicated by the MaxChannelTime has elapsed.

The Max Channel Time field shall be set to the MaxChannelTime of the MLME-SCAN.request primitive as defined in 9.4.2.176.

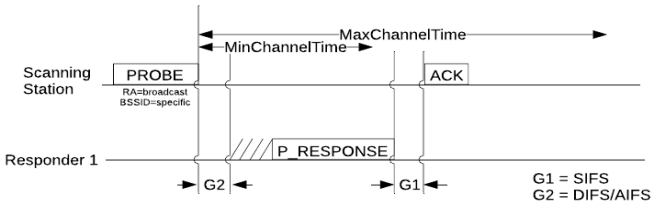

Figure 11-7—Active scanning by a non-DMG STA with a Probe Request frame addressed to a specific BSSID

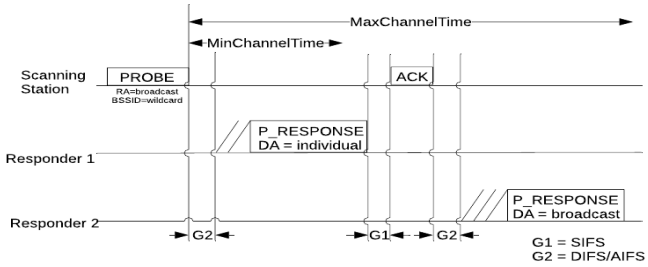

Figure 11-8—Active scanning by a non-DMG STA with a Probe Request frame addressed to wildcard BSSID

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.1.4.3.3 Active scanning procedure for a DMG STA

Upon receipt of the MLME-SCAN.request primitive with ScanType parameter indicating an active scan, a DMG STA shall use the following procedure.

For each channel to be scanned:

a) Wait until the ProbeDelay time has expired or a PHY-RXSTART.indication primitive has been received.

b) Initialize a timer to 0 and start it running.

c) If the DiscoveryMode parameter of the MLME-SCAN.request primitive is equal to 1, generate DMG Beacon frames as (described in 11.1.3.4) for a period no longer than MaxChannelTime.

d) If a DMG Beacon frame is received before the timer reaches MaxChannelTime and beamforming training is required (see 10.41), perform beamforming training defined in 10.41.5.

e) Perform the basic access procedure defined in 10.3.4.2.

f) If an SSW-Feedback frame is transmitted or received in step d), then:

   1) Send a Probe Request frame to the broadcast address or
      — Following the transmission of an SSW-Feedback frame, send a Probe Request frame to the MAC address of the STA addressed by the SSW-Feedback frame.
      — Optionally, following the reception of an SSW-Feedback frame, send a Probe Request frame to the MAC address of the STA that transmitted the SSW-Feedback frame.

      In all Probe Request frames sent under step f) 1), the Probe Request frame is sent with the SSID and BSSID from the received MLME-SCAN.request primitive and includes the DMG Capabilities element. The basic access procedure (10.3.4.2) is performed prior to the Probe Request frame transmission.

   2) When the SSID List parameter is present in the MLME-SCAN.request primitive, send zero or more Probe Request frames to the broadcast address. Each Probe Request frame is sent with an SSID indicated in the SSID List parameter and the BSSID from the received MLME-SCAN.request primitive and includes the DMG Capabilities element. The basic access procedure (10.3.4.2) is performed prior to each Probe Request frame transmission.

g) If an SSW-Feedback frame is neither transmitted nor received in step d), then:

   1) Optionally send a Probe Request frame to the broadcast address. The Probe Request frame is sent with the SSID and BSSID from the received MLME-SCAN.request primitive and includes the DMG Capabilities element. An EDMG STA may transmit the Probe Request frame using a quasi-omni antenna pattern and, in this case, may send the Probe Request frame using an EDMG BRP-RX PPDU. The basic access procedure (10.3.4.2) is performed prior to the Probe Request frame transmission.

   2) When the SSID List is present in the MLME-SCAN.request primitive, send zero or more Probe Request frames to the broadcast address. Each Probe Request frame is sent with an SSID indicated in the SSID List and the BSSID from the MLME-SCAN.request primitive and includes the DMG Capabilities element. An EDMG STA may transmit the Probe Request frame using a quasi-omni antenna pattern and, in this case, may send the Probe Request frame using an EDMG BRP-RX PPDU. The basic access procedure (10.3.4.2) is performed prior to each Probe Request frame transmission.

h) Respond with a Probe Response frame to any Probe Request frame received, subject to the conditions in 11.1.4.3.4.

NOTE—The requirement to respond with a Probe Response frame also applies to a non-AP non-PCP DMG STA that is not a member of a PBSS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

i) Process all Probe Response frames received until the timer reaches MaxChannelTime, constructing BSSDescriptions corresponding to the Probe Response frames that match the criteria specified in the MLME-SCAN.request primitive.

j) Set the NAV to 0 and scan the next channel.

When all channels in the ChannelList have been scanned, the MLME shall issue an MLME-SCAN.confirm primitive with the BSSDescriptionSet containing all the BSSDescriptions constructed during the scan.

See Figure 11-9 for DMG STAs that generate DMG Beacon frames with the Discovery Mode field set to 1, where STA A and STA B are actively scanning at the same time and STA B is not a member of a PBSS. STA A may be a member of a PBSS.

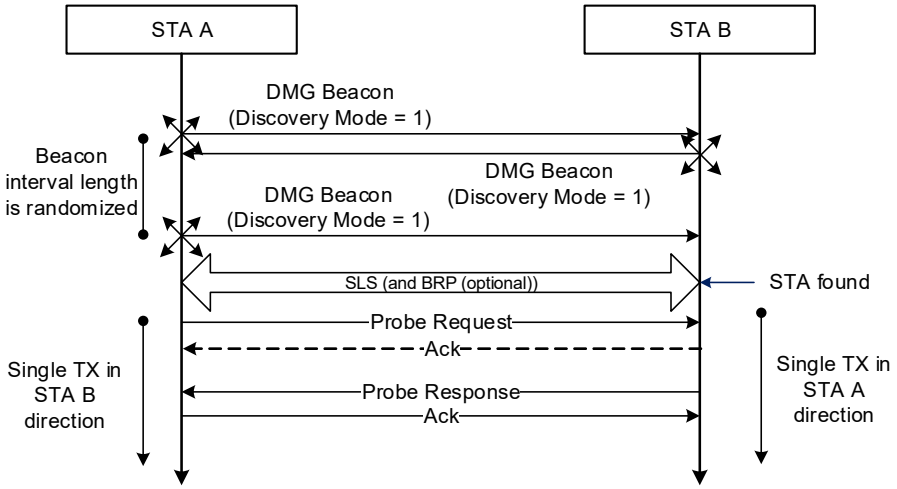

Figure 11-9—Active scanning for DMG STAs

11.1.4.3.4 Criteria for sending a response

If a STA that receives a Probe Request frame is not in a multiple BSSID set, that STA shall send the Probe Response frame(s), subject to the criteria below. If a STA that receives a Probe Request frame is in a multiple BSSID set, the STA corresponding to the transmitted BSSID shall send the Probe Response frame(s), subject to the criteria below; other STAs in the multiple BSSID set shall not send a Probe Response frame.

An EDMG STA that receives a Probe Request frame before performing transmit antenna training may use a quasi-omni antenna pattern for transmission of the Probe Response. An EDMG STA that receives a Probe Request frame transmitted using an EDMG BRP-RX PPDU may perform receive training and select a transmit sector if the STA supports antenna reciprocity or antenna pattern reciprocity as indicated by setting the DMG Antenna Reciprocity field or Antenna Pattern Reciprocity field in the DMG Capabilities element to 1 respectively, for transmission to the transmitter of the Probe Request frame based on the result of the receive training.

A STA that receives a Probe Request frame shall not respond if any of the following apply:

a) The STA does not match any of the following criteria:
   1) The STA is an AP.
   2) The STA is an IBSS STA.
   3) The STA is a mesh STA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

4) The STA is a DMG STA that is not a member of a PBSS and that is performing active scan as defined in 11.1.4.3.3.

5) The STA is a PCP.

b) The Address 1 field of the Probe Request frame contains an individual address and one of the following criteria is met:

1) The STA is not a member of a multiple BSSID set, and the individual address is not the MAC address of the STA.

2) The STA is a member of a multiple BSSID set, and the individual address does not match the BSSID of any of the BSSs in the multiple BSSID set.

c) The STA is a non-AP STA in a DMG infrastructure BSS and the Address 1 field of the Probe Request frame contains the broadcast address.

d) The STA is a non-PCP STA in a PBSS and the Address 1 field of the Probe Request frame contains the broadcast address.

e) The STA is in an IBSS and did not transmit a Beacon or DMG Beacon frame since the last TBTT, and the Address 1 field of the Probe Request frame contains the broadcast address.

f) The STA is a mesh STA and either of the following criteria are met:

1) The Probe Request frame does not contain a Mesh ID element.

2) The Mesh ID element in the Probe Request frame is present but does not contain the wildcard mesh ID and does not match the mesh ID of the MBSS with which the STA is peered.

g) The STA is not a mesh STA and none of the following criteria are met:

1) The SSID in the Probe Request frame is the wildcard SSID.

2) The SSID in the Probe Request frame matches the SSID of the STA's BSS.

3) The STA is an AP that is in the same colocated AP set as a 6 GHz AP, the SSID in the Probe Request frame matches the SSID of the 6 GHz AP, and the STA reports the colocated 6 GHz AP in Beacon and Probe Response frames (see 11.53).

4) The STA is a member of a multiple BSSID set and the SSID in the Probe Request frame matches any of the SSIDs of the members of that multiple BSSID set.

5) dot11SSIDListImplemented is true, and the SSID List element is present in the Probe Request frame and includes the SSID of the STA's BSS.

6) dot11SSIDListImplemented is true, the STA is an AP that is in the same colocated AP set as a 6 GHz AP, the SSID List element is present in the Probe Request frame and includes the SSID corresponding to the colocated 6 GHz AP, and the AP reports the colocated 6 GHz AP in Beacon and Probe Response frames (see 11.53).

7) dot11ShortSSIDListImplemented is true, and the Short SSID List element is present in the Probe Request frame and includes the short SSID corresponding to the SSID of the STA's BSS.

8) dot11ShortSSIDListImplemented is true, the STA is an AP that is in the same colocated AP set as a 6 GHz AP, the Short SSID List element is present in the Probe Request frame and includes the short SSID corresponding to the SSID of the 6 GHz AP, and the AP reports this 6 GHz AP in its Beacon and Probe Response frames (see 11.53).

h) The STA is not a mesh STA and the Address 3 field of the Probe Request frame does not contain a wildcard BSSID and one of the following criteria is met:

1) The STA is not a member of a multiple BSSID set and the Address 3 field of the Probe Request frame does not match the BSSID of the STA's BSS.

2) The STA is a member of a multiple BSSID set and the Address 3 field of the Probe Request frame does not match the BSSID of any of the BSSs in the multiple BSSID set.

i) The STA has dot11InterworkingServiceActivated equal to true and the Probe Request frame contains an Interworking element and an Extended Capabilities element whose Interworking field contains the value 1, and at least one of the following criteria is not met:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

1) The HESSID field of the Interworking element is absent, or is present and contains the wildcard HESSID or matches the HESSID field of the InterworkingInfo parameter of the last MLME-START.request or MLME-JOIN.request primitive.
2) The Access Network Type field of the Interworking element contains the wildcard access network type or matches the access network type of the STA.

j) The Probe Request frame contains a DSSS Parameter Set element in which the Current Channel field contains a value that is not the same as dot11CurrentChannel.

k) The STA is a DMG STA, the transmit antenna of the DMG STA is not trained to transmit to the STA from which the Probe Request frame was received, and the STA is not an EDMG STA that intends to transmit the response using a quasi-omni antenna pattern.

A FILS STA shall not respond to a Probe Request frame if any of the following criteria is met for a FILS Request Parameters element contained in the Probe Request frame:

1) If the FILS Criteria field is present in the FILS Requests Parameters element and the Max Delay Limit field of the FILS Request Parameters indicates a delay shorter than the selected average access delay of the responding STA. The BSS Delay Criterion field of the FILS Criteria field of the FILS Request Parameters element indicates the selected average access delay for the comparison as defined in Table 9-336. The Max Delay Limit field contains the maximum selected average access delay. If the compared Average Access Delay indicates Measurement not available, the STA shall respond and the response shall include a BSS AC Access Delay element as described in 9.4.2.42 and Average Access Delay as described in 9.4.2.37 or Average Access Delay as described in 9.4.2.37 that was requested in the Probe Request frame. If the compared Average Access Delay indicates Service unable to access channel, the response shall not be transmitted.
2) If the FILS Criteria field is present in the FILS Requests Parameters element and the PHY Support Criterion of the FILS Criteria field of the FILS Request Parameters element is 1 and the responding STA is not HT capable.
3) If the FILS Criteria field is present in the FILS Requests Parameters element and the PHY Support Criterion of the FILS Criteria field of the FILS Request Parameters element is 2 and the responding STA is not VHT capable.
4) If the FILS Criteria field is present in the FILS Requests Parameters element and the PHY Support Criterion of the FILS Criteria field of the FILS Request Parameters element is 3 and the responding STA is not HE capable.
5) If the Minimum Data Rate is present in the FILS Request Parameters element and the Minimum Data Rate field of the FILS Request Parameters element indicates a data rate higher than the one that is provided over the MAC SAP.
6) If the RCPI Limit field is present in the FILS Request Parameters element and either of the following conditions is true:
   — The RCPI of the Probe Request frame > –90 dBm + the RCPI Limit field of the FILS Request Parameters element.
   — The RCPI Limit field of the FILS Request Parameters element contains value 255.
7) If the OUI Response Criteria field is present in the FILS Request Parameters element and if any of the OUIs specified by the OUI Response Criteria field are not in the list of known OUIs configured in the AP (see Known OUIs, 6.5.11.2.2).

If the FILS Request Parameters element is present in the Probe Request frame, the responding FILS STA should discard any Probe Response frame that has not been transmitted as a response to the Probe Request frame when the elapsed time measured from the end of the reception of the Probe Request frame by the MAC entity of the responding STA exceeds the time indicated by the Max Channel Time field of the FILS Request Parameters element of the Probe Request frame. If the FILS Request Parameter element is not present in the Probe Request frame, transmission time of the Probe Response frame to the Probe Request frame by the responding STA is only limited by the retransmission procedure in 10.23.2.12.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—It is possible for the STA to leave the channel on which it sent the Probe Request frame prior to MaxChannelTime. Should this occur the STA might not receive some of the Probe Response frames transmitted.

An individually addressed Probe Response frame, subject to the criteria above, shall be transmitted to all non-FILS STAs from which a Probe Request frame is received.

If a FILS STA has dot11FILSOmitReplicateProbeResponses equal to false, an individually addressed Probe Response frame, subject to the criteria above, shall be transmitted to all STAs from which a Probe Request frame is received.

If a FILS STA receives one or more Probe Request frame(s) and the STA has dot11FILSOmitReplicateProbeResponses equal to true, then the responding STA shall respond, subject to the criteria above, via the next Beacon frame, a broadcast Probe Response frame, or one or more individually addressed Probe Response frames.

The FILS STA shall respond with the next Beacon frame, as described in 11.1.3 (Maintaining synchronization), to Probe Request frames addressed to individual or broadcast address if all of the following conditions are met:

— The STA is queuing a Beacon frame for transmission;
— The next TBTT of the responding STA is within dot11FILSBeaconResponseWindow;
— The next TBTT is no later than any deadline of Max Channel Time indicated in the FILS Request Parameter element of the Probe Request frame(s), if present; and
— The Beacon frame contains all elements requested by the Request element.

If the next Beacon frame is not used as a response, a Probe Response frame is transmitted. The Probe Response frame shall be addressed to the broadcast or the address of the transmitter of the Probe Request frame. The Probe Response frame may be transmitted to all or some of the Probe Request frames received from FILS STAs. A first FILS STA may choose not to respond to Probe Request frames from a second FILS STA addressed to the broadcast address if the first STA receives an acknowledged Probe Response frame addressed to the second STA containing the SSID of the first STA's BSS. A non-S1G AP shall remain in the awake state, and shall respond to Probe Request frames, subject to the criteria above.

An S1G AP that is awake shall respond to NDP Probe Request frames or Probe Request frames, subject to the criteria above. The response to the NDP Probe Request frames or Probe Request frames shall have the same CH_BANDWIDTH as the preceding NDP Probe Request frame or Probe Request frame. The S1G AP may send a PV1 Probe Response frame instead of a Probe Response frame as specified in 11.1.4.3.7.

NOTE 2—This rule does not allow an S1G AP to respond with a PV1 Probe Response frame or Probe Response frame in 1 MHz channel width after receiving a NDP Probe Request frame or Probe Request frame in 2 MHz channel width.

An IBSS STA that sent a Beacon or DMG Beacon frame shall remain in the awake state, and shall respond to Probe Request frames, subject to the criteria above, until a Beacon or DMG Beacon frame with the BSSID of the STA's IBSS is received.

A mesh STA or PCP that is awake shall respond to Probe Request frames, subject to the criteria above.

NOTE 3—Results of the procedures defined in this subclause are as follows:

a) Infrastructure BSS: The AP is always awake to respond to Probe Request frames.
b) IBSS: At least one STA is awake to respond to Probe Request frames. More than one STA might respond to any given Probe Request frame, particularly when more than one STA transmitted a Beacon or DMG Beacon frame following the most recent TBTT, either due to not receiving a previous Beacon or DMG Beacon frame or due to collisions between beacon transmissions.
c) MBSS or PBSS: At any given time it might be the case that no STA is awake to respond to Probe Request frames.

11.1.4.3.5 Active scanning for relay discovery

An S1G STA that is performing an active scan to discover operating APs, or S1G relay APs may include the S1G Relay Discovery element (see 9.4.2.206) in the Probe Request frame. This element provides information on the QoS criteria on the relay path.

The active scanning procedure for relay AP is similar to the active scanning procedure outlined in 11.1.4.3.

An S1G relay AP receiving Probe Request frames may respond with a Probe Response or a PV1 Probe Response frame, if the criteria outlined in 11.1.4.3.2 are met. An S1G relay AP shall not respond with a Probe Response, or a PV1 Probe Response, frame if the QoS criteria on the relay path specified in the S1G Relay Discovery element (see 9.4.2.206) cannot be satisfied.

An S1G relay AP sending Probe Response, or PV1 Probe Response frames may include the S1G Relay Discovery element (see 9.4.2.206) to carry link budget information between the S1G relay AP and S1G root AP.

An S1G STA may use the information received from different S1G relay APs to determine a suitable S1G relay AP for association. The S1G relay AP selection is made by the S1G STA, and the specific selection procedure is up to the implementation.

11.1.4.3.6 NDP Probing

An NDP probing procedure is used to reduce the energy consumption during the scanning procedure. Upon receipt of the MLME-SCAN.request primitive with ActiveScanType parameter indicating an NDP, a STA for which dot11NDPProbingActivated is true shall transmit an NDP Probe Request frame, instead of a Probe Request frame, that has either a short SSID or an access network option. The NDP probing procedure is allowed when an S1G STA knows the operating frequency bands and regulatory domains. A non-S1G STA shall not transmit an NDP Probe Request frame.

APs receiving an NDP Probe Request frame shall transmit a broadcast Probe Response only if

a) The compressed SSID in the NDP Probe Request frame is the specific short SSID of the AP's BSS.
b) The access network option in the NDP Probe Request frame is the access network option of the AP.

The response to the NDP Probe Request frame shall be a PV1 Probe Response frame if all the criteria below are satisfied:

— dot11PV1ProbeResponseOptionImplemented is true at the responding STA.
— The Requested Probe Response Type field in the NDP Probe Request frame is set to 0.

If any of the criteria above is not satisfied, then the response to the NDP Probe Request frame shall be a Probe Response frame. The AP shall follow the channel access procedure defined in 9.3.4.3 to transmit the probe response.

If PHY-CCA.indication(BUSY) primitive has not been detected before the ActiveScanningTimer reaches MinChannelTime, then set NAV to 0 and scan the next channel.

NOTE—If the STA receives a PV1 Probe Response frame, it might transmit a Probe Request frame or wait for a Beacon frame to obtain more information.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An illustration of the NDP probing procedure is shown in Figure 11-10 .

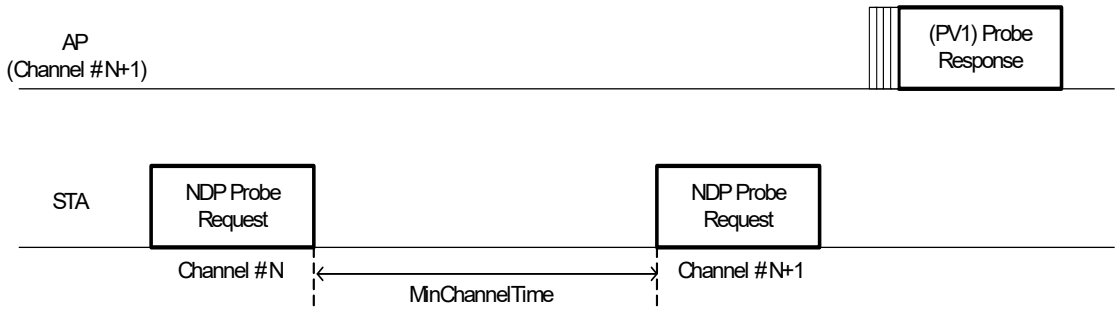

Figure 11-10—NDP probing procedure

11.1.4.3.7 Active scanning using PV1 Probe Response

An S1G STA may use PV1 Probe Response frames as defined in 9.8.5.3 instead of Probe Response frames as defined in 9.3.3.10. PV1 Probe Response frame is used for reducing overhead of using long Probe Response frame in active scanning by optimizing the frame format and by allowing STA to request minimum information that is required for association with the responding STA to be included in the PV1 Probe Response frame.

An S1G STA may solicit PV1 Probe Response frames by including the PV1 Probe Response Option element defined in 9.4.2.208 in the Probe Request frames it transmits or by setting the Requested Probe Response Type field in the NDP Probe Request frame it transmits to 0.

A STA may include the PV1ProbeResponseOption parameter in the MLME-SCAN.request primitive to include the PV1 Probe Response Option element in the Probe Request frames. The requesting STA indicates which optional information is requested to be included in the PV1 Probe Response frame to the responding STA by setting one or more bits in the Probe Response Option bitmaps in the PV1 Probe Response Option element.

An S1G STA responds to the probe request subject to the criteria defined in 11.1.4.3.4. The response to the probe request shall be a PV1 Probe Response frame if all the criteria below are satisfied:

— dot11PV1ProbeResponseOptionImplemented is true at the responding STA.
— A PV1 Probe Response Option element is included in the received Probe Request frame.

If any of the criteria above is not satisfied, then the response to the probe request shall be a Probe Response frame.

When an NDP Probe request frame is used instead of a Probe Request frame, the response shall be either a PV1 Probe Response frame or a Probe Response frame as described in 11.1.4.3.6.

If any of the criteria above is not satisfied, then the response to the NDP Probe Request frame shall be a Probe Response frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An S1G STA that responds with a PV1 Probe Response frame shall include the following information in the frame:

- The elements that are requested by the requesting STA as indicated in the PV1 Probe Response Option element contained in the received Probe Request frame.
  - If a bit in a Probe Response Option bitmap in the PV1 Probe Response Option element is equal to 1, then the corresponding element is requested and it shall be included in the PV1 Probe Response frame (see 9.4.2.208).
  - If the S1G Beacon Compatibility element is included in the PV1 Probe Response frame, then it shall be included as the first optional element and shall be generated no later than the Timestamp field of the frame and not earlier than $2^{31} - 1$ μs.
- Either the SSID element or the Short SSID field.
  - If the Request Full SSID field in the PV1 Probe Response Option element is equal to 1, then the SSID element shall be present in the PV1 Probe Response frame and the Short SSID field shall not be present. If it is equal to 0 or is not present in the PV1 Probe Response Option element, then the Short SSID field shall be present and the SSID element shall not be present.
- The 1 MHz Channel Primary Location field in the Frame Control field shall indicate the location of the 1 MHz primary channel within the 2 MHz primary channel.

PV1 Probe Response frames shall be sent as individually addressed frames to the address of the STA that generated the Probe Request frame.

Upon reception of a PV1 Probe Response frame that includes an S1G Beacon Compatibility element an S1G STA that included the PV1 Probe Response Option element in a previously transmitted Probe Request frame or that set the Requested Probe Response Type to 0 in a previously transmitted NDP Probe Request frame may update its TSF timer using the same TSF timer update procedure described in 11.1.3.10.3 for S1G Beacon frames.

11.1.4.3.8 Non-scanning probe request transmission

A STA may send an individually addressed or broadcast Probe Request frame to a peer STA that it has determined is within range, in order to solicit information contained within a response frame, see 11.1.4.3.9. When the Probe Request frame is sent to the broadcast address, the Address 3 (BSSID) field shall be set to the MAC address of the peer STA.

NOTE 1—A STA might determine that a peer STA is within range by, for example, receiving a frame from that peer STA or, if the peer STA is an AP, by receiving a frame from another AP that corresponds to a colocated BSS of the AP.

NOTE 2—Transmission of an individually addressed frame can provide more reliable delivery to a peer STA since it is acknowledged and retransmit procedures apply. The responder STA responds in accordance with 11.1.4.3.4. See Figure 11-11 for an example in which both the probe request and response are individually addressed. When a STA has not determined that a peer STA is in range, Probe Request frames it sends to discover the peer STA are transmitted in accordance with the active scanning procedures in 11.1.4.3.4. For a non-DMG STA, such Probe Request frames are always sent to the broadcast address.

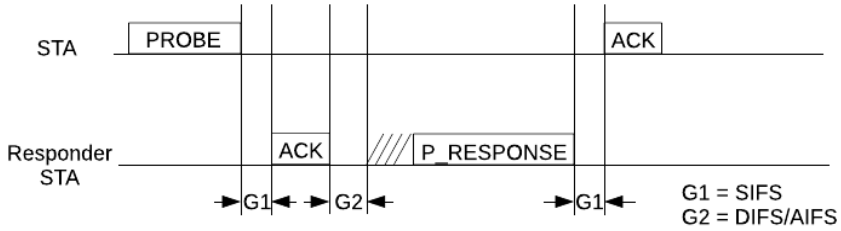

Figure 11-11—Example of a probe request addressed to an individual address

11.1.4.3.9 Contents of a probe response

A STA that responds to a Probe Request frame according to 11.1.4.3.4 shall transmit a Probe Response frame or a Beacon frame to the STA that transmitted the Probe Request frame.

A FILS STA that transmits a Probe Response frame shall either set the Address 1 field to the address of the STA that generated the probe request or to the broadcast address if the STA that generated the probe request indicated FILS Capability. A non-FILS STA that transmits a Probe Response frame shall set the Address 1 field to the address of the STA that generated the probe request.

When a FILS AP responds to a Probe Request frame containing a FILS Capability field in the Extended Capabilities element equal to 1, and when both the FILS AP and the FILS STA that transmitted the Probe Request frame support other than DSSS/CCK rates (see Clause 15 or Clause 16), the AP shall transmit a Probe Response frame in a PPDU using a rate other than a DSSS/CCK.

A STA having dot11InternetworkingServiceActivated true may include in the Probe Response frame a CAG Number element containing one or more current version numbers of the CAG information associated with the AP, where each version number is associated with an advertisement protocol. The current CAG information associated with the AP can be acquired by the GAS query mechanism as described in 11.22.3 using the associated advertisement protocol.

If there was a Request element, Extended Request element, or Vendor Specific Request element in the Probe Request frame, then:

— Each element that is listed by a non-FILS STA in the Request element, Extended Request element(s), or Vendor Specific Request element and that is supported by the STA shall be included in the Probe Response frame. An element that is listed in a Request element, Extended Request element, or Vendor Specific Request element and that is not supported by the STA shall not be included. Each element requested by a FILS STA in a Request element shall be included in the Probe Response frame or a Beacon frame if the responding FILS STA supports that element.

— Elements that would not have been included otherwise shall be included after all of the elements that would have been included even in the absence of the Request element, Extended Request element, or Vendor Specific Request element.

— Elements that would have been included even in the absence of the Request element, Extended Request element, or Vendor Specific Request element shall be included in their normal position (see Table 9-69), and may be included again after all of the elements that would have been included even in the absence of the Request element.

  NOTE—An element that would necessarily be included anyway is not expected to be requested.

— Elements after all of the elements that would have been included even in the absence of the Request element, Extended Request element, or Vendor Specific Request element shall be included in the order that they appear in the (Extended) Request element(s) of the Probe Request frame.

— If dot11RadioMeasurementActivated is true and the RCPI element was requested, an RCPI element containing the RCPI of the Probe Request frame shall be included. If no measurement result is available, the RCPI value shall be set to indicate “Measurement not available” (see Table 9-215).

— If dot11RadioMeasurementActivated is true and the RSNI element was requested, an RSNI element containing the RSNI of the Probe Request frame shall be included. If no measurement result is available, the RSNI value shall be set to indicate that a measurement is not available. (see 9.4.2.39).

— If a Probe Request frame includes a Request element that contains the element ID of the Reduced Neighbor Report element, a Probe Response frame or a Beacon frame if transmitted may include the Reduced Neighbor Report element if the criteria as defined in 11.1.4.3.4 (Criteria for sending a

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

response) are met for the included BSS. The reported BSSs may have different primary channels to the responding STA.

11.1.4.3.10 PCP selection in a PBSS

The PCP selection procedure is performed by the SME when:

— An MLME-SCAN.confirm primitive is received in response to an MLME-SCAN.request primitive with the value of the ScanType parameter equal to ACTIVE and BSSType parameter equal to PERSONAL

— There is a PCP handover (see 11.27.2)

The decision of whether a STA or its peer STA is the PCP depends on a comparison of their respective PCP factors (self_PCP_factor and peer_PCP_factor). The PCP factor, for a DMG STA and a CDMG STA operating on a 2.16 GHz channel, defined in Figure 11-12 , is the concatenation of the value of some of the fields from the DMG Capabilities element transmitted by the STA (see 9.4.2.126). The PCP factor for a CDMG STA operating on a 1.08 GHz channel is constructed by concatenating the value of select fields present in the STA's DMG Capabilities element and the Supported Channel Width Set field. The PCP factor for a CDMG STA operating on a 1.08 GHz channel is defined in Figure 11-13 .

NOTE—According to convention, the least significant bit is the leftmost bit (B0).

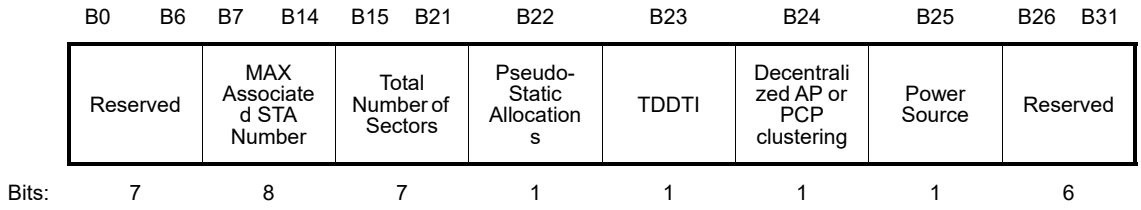

Figure 11-12—PCP factor for a DMG STA

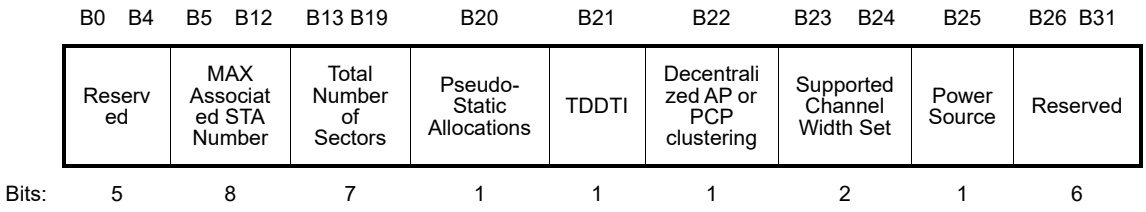

Figure 11-13—PCP factor for a CDMG STA operating on a 1.08 GHz channel

The Supported Channel Width Set field in Figure 11-13 is obtained via encoding based on the supported channel widths that are indicated by the Operating Classes field of the received Country element or the Supported Operating Classes element of the peer STA. The encoding of the Supported Channel Width Set field is given in Table 11-1.

Table 11-1—Encoding of the Supported Channel Width Set field

Bit 23	Bit 24	Meaning
0	0	The CDMG STA supports 1.08 GHz channel width in 60 GHz band.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table 11-1—Encoding of the Supported Channel Width Set field *(continued)*

0	1	The CDMG STA supports both the 1.08 GHz and 2.16 GHz channel widths in 60 GHz band.
All other combinations		Reserved

For each peer STA reported as part of an MLME-SCAN.confirm primitive or considered as part of a PCP handover, the STA proceeds as follows. If the STA's value of self_PCP_factor is greater than the value of peer_PCP_factor or if the values are equal and the MAC address of the STA is greater than (see 12.7.1 for MAC address comparison) the MAC address of the peer STA contained in the peer STA's DMG Capabilities element, the STA becomes a candidate PCP. Otherwise, the STA does not become a candidate PCP.

Subclause 11.1.4.4.2 specifies the rules followed by the SME of a candidate PCP to start a PBSS.

11.1.4.3.11 Enhanced FILS active scanning to preferred AP

A FILS non-AP STA may maintain one or more BSS configuration parameter sets. A BSS configuration parameter set is obtained from a preferred AP by using a preferred AP determination process that is out of scope of this standard. Each BSS configuration parameter set may be different according to the preferred AP's capabilities. A BSS configuration parameter set is a set of elements of the Beacon frame or the Probe Response frame. The following dynamic elements are excluded from a BSS configuration parameter set:

— TIM element
— Quiet element
— BSS Load element
— EDCA Parameter element
— BSS Average Access Delay element
— BSS Available Admission Capacity element
— BSS AC Access Delay element
— Time Advertisement element
— Emergency Alert Identifier element
— Beacon Timing element
— QLoad Report element
— Extended BSS Load element
— Quiet Channel element
— Reduced Neighbor Report element (see NOTE 1)
— CAG Number element
— AP-CSN element
— DILS element
— Fragment element (see NOTE 2)
— TWT element
— MU EDCA Parameter Set element
— NDP Feedback Report Parameter Set element
— UORA Parameter Set element
— Spatial Reuse Parameter Set element
— HE BSS Load element
— Quiet Time Parameter element

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— Vendor Specific element

NOTE 1—The Reduced Neighbor Report element is excluded from the BSS configuration parameter set based on the principle that an element is excluded from the BSS configuration parameter set if that element has no impact on a FILS STA's ability of using AP-CSN to make a decision of initiating an association procedure with an AP without receiving Beacon or Probe Response frame from the AP.

NOTE 2—Any change in a Fragment element is considered under the context of the element being fragmented by the Fragment element.

If a vendor-specific subelement is included in an element within the BSS configuration parameter set, the AP-CSN does not provide any indication regarding if that vendor-specific subelement has changed or not, and AP-CSN is not increased if the only change within the BSS configuration parameter set is due to the change to a vendor-specific subelement embedded in an element within the BSS configuration parameter set.

NOTE 3—A vendor-specific subelement can be included in a BSS configuration parameter set within one of the permitted elements, even though the Vendor Specific element is excluded.

A FILS AP maintains an AP-CSN list consisting of the current AP-CSN value and an implementation-dependent number of zero of more previous AP-CSN values. The AP initializes the AP-CSN to a random integer value in the range 0 to 255. For each maintained previous AP-CSN value, the AP also maintains the identifiers of the changed elements.

NOTE 4—The AP maintains the AP-CSN values in the AP-CSN list for a duration whose value is out of the scope of this standard.

An AP maintaining an AP-CSN list shall increase the current AP-CSN value (modulo 256) by one if an update occurs to any of the fields or elements within the BSS configuration parameter set.

A FILS AP may provide FILS STAs its AP-CSN value by sending a Beacon frame or a Probe Response frame including an AP-CSN element (as defined in 9.4.2.180).

A FILS non-AP STA identifies an BSS configuration parameter set by its associated AP-CSN value and the AP's BSS's BSSID.

A FILS non-AP STA may send a Probe Request frame that includes an AP-CSN element (as defined in 9.4.2.180) if the STA has the BSS configuration parameter set associated with the AP-CSN of an AP. When sending such a Probe Request frame, the FILS non-AP STA shall send it to the broadcast address and set the Address 3 (BSSID) field in the Probe Request frame to the BSSID of the AP's BSS.

When a FILS AP receives a Probe Request frame with an AP-CSN element where the Address 3 (BSSID) field matches the BSSID of this AP's BSS, and the criteria for responding to a Probe Request frame (11.1.4.3.4) are met, the AP sends a Probe Response frame according to comparison result, as follows:

a) If the AP does not maintain an AP-CSN list, the AP sends a Probe Response frame.
b) If the received AP-CSN element matches with the current AP-CSN of the AP, the AP sends an optimized Probe Response frame including mandatory fields (i.e., Timestamp, Capability, and Beacon Interval), the current AP-CSN element, and one or more elements among dynamic elements defined in this subclause.
c) If the received AP-CSN element that matches one of the previous AP-CSN in the AP-CSN list, the AP sends an optimized Probe Response frame including mandatory fields, the current AP-CSN element, the elements that need to be updated at the STA, and one or more elements among dynamic elements defined in this subclause.

If the received AP-CSN value does not match with any of AP-CSN values in the AP-CSN list, the AP shall send a Probe Response frame with its current AP-CSN.

11.1.4.4 Initializing a BSS

11.1.4.4.1 General

Upon receipt of an MLME-START.request primitive, a STA shall determine the BSS's BSSID (as described in 11.1.4), select channel synchronization information, select a beacon period, initialize and start its TSF timer, and begin transmitting Beacon frames if the STA is a neither a DMG nor an S1G STA, or DMG Beacon frames if the STA is a DMG STA, or S1G Beacon frames if the STA is an S1G STA. See 9.3.3.2 for the description of a Beacon frame, and see 9.3.4.2 for the description of a DMG Beacon frame. Upon receipt of an MLME-START.request primitive, an S1G STA with dot11ShortBeaconInterval equal to true shall select a short beacon period and begin transmitting S1G Beacon frames.

11.1.4.4.2 Initializing a DMG BSS

Prior to choosing a suitable operating channel and starting a BSS, the SME of a DMG STA should perform a channel scan to ascertain the quality of each channel that the STA supports. The rules for choosing a suitable operating channel are implementation specific and might be subject to regulatory requirements.

When a STA's MAC receives an MLME-START.request primitive, the MAC shall attempt to start a BSS. The STA may listen for a duration of aMinChannelTime, the listening duration, in the channel specified by the SME in the request. If the STA determines the channel is suitable for BSS operation at the end of this listening duration, the STA initializes the BSS by commencing transmission of DMG Beacon frames according to 11.1.3.3 in the case of a PBSS or an infrastructure BSS and according to 11.1.3.5 in the case of an IBSS. If AP or PCP clustering is in use on the selected channel, the DMG Beacon frame transmission by an AP or PCP commences following the additional rules described in 10.39.

For an EDMG BSS, an AP or PCP shall set the Channel BW Configuration subfield within the EDMG Operation element it transmits to a valid value as defined in Table 11-2.

Table 11-2—Valid Channel BW Configuration subfield values

EDMG Operation element configuration			
BSS Operating Channel subfield in EDMG Operation element		Valid Channel BW Configuration subfield values when primary channel is not adjacent to secondary channel	Valid Channel BW Configuration subfield values when primary channel is adjacent to secondary channel
Total number of subfields set to 1 in BSS Operating Channels field	Total number of adjacent channels indicated by BSS Operating Channels field		
1	No adjacent channels	4	—
2, 3, or 4	No adjacent channels	8	—
2, 3, or 4	Two adjacent channels	8	5, 8, 9
4	Pair of two adjacent channels	—	8, 9, 12, 13
3 or 4	Three adjacent channels	8	6, 8, 9, 10
4	Four adjacent channels	—	7, 11, 12, 13, 14, 15

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the STA determines that no channels are suitable or available, it responds with an MLME-START.confirm primitive with a ResultCode of NOT_SUPPORTED. Otherwise, the MLME shall respond with an MLME-START.confirm primitive with a ResultCode of SUCCESS.

The SME should issue an MLME-START.request primitive with BSSType parameter equal to PERSONAL for at least one network in which the STA becomes a candidate PCP as defined in 11.1.4.3.10. If the STA becomes a candidate PCP of more than one network, the SME may issue an MLME-START.request primitive with BSSType parameter equal to PERSONAL for any of the remaining networks. In either case, the MLME-START.request primitive should be issued no later than 4×aMaxBIDuration after the MAC receives an MLME-SCAN.confirm primitive.

The SME should not issue an MLME-START.request primitive with BSSType parameter equal to PERSONAL for networks in which the STA does not become a candidate PCP as defined in 11.1.4.3.10. If the SME issues the MLME-START.request primitive under this circumstance, it shall not be issued if less than 4 × aMaxBIDuration has elapsed since the MAC received the MLME-SCAN.confirm primitive.

11.1.4.5 Synchronizing with a BSS

Upon receipt of an MLME-JOIN.request primitive, a STA shall adopt the BSSID in the request. Upon receipt of a Beacon frame from the BSS, a STA shall adopt the TSF timer value of the parameters in the Beacon frame using the algorithm described in 11.1.3.9, and the MLME shall issue an MLME-JOIN.confirm primitive indicating the operation was successful.

In addition to these synchronization parameters, a STA joining an infrastructure BSS adopts each of the parameters found in the SelectedBSS parameter of the MLME-JOIN.request primitive except Local time, Capability Information, BSSBasicRateSet parameters, and HT Capabilities element. Local time is not adopted but is used in adopting the TSF as described in 11.1.3.9. The Capability Information reflects the capabilities of the sender and is not adopted but may be used to determine local configuration or behavior. The BSSBasicRateSet parameter is not adopted but may determine if the STA can join the BSS.

If the JoinFailureTimeout timer expires prior to the receipt of a Beacon frame from the BSS, the MLME shall issue an MLME-JOIN.confirm primitive indicating the operation was unsuccessful.

If dot11MultiDomainCapabilityActivated is true, a STA that is joining an infrastructure BSS and receives a Beacon or Probe Response frame containing a Country element shall adopt the applicable parameters included in that Country element, and the dot11RegDomainsSupportedEntry shall be set to Other.

In addition to adopting the synchronization parameters as described in the first paragraph of this subclause, a STA joining an IBSS shall adopt each of the parameters found in the SelectedBSS parameter of the MLME-JOIN.request primitive according to the rule found for that parameter in the IBSS adoption column of the matching row of the BSSDescription table found in 6.5.3.3.2 when those parameters exist at the STA. Parameters adopted by a STA when joining an IBSS shall not be changed by the STA except when adopting parameters following the reception of a Beacon frame with a later timestamp as described in 11.1.5. When an IBSS contains STAs with a mix of STA capabilities, e.g., non-HT and HT, a STA in the IBSS adopts the behavioral parameters of the last beacon with the highest TSF (e.g., a HT STA does not continue use of HT and does not include an HT Operations element in its beacons).

In addition to the table entries in 6.5.3.3.2, if dot11MultiDomainCapabilityActivated is true, a STA that is joining an IBSS and receives a Beacon or Probe Response frame containing a Country element shall adopt the applicable parameters included in that Country element, and the dot11RegDomainsSupportedEntry shall be set to Other.

A DMG STA shall support transmitting DMG Beacon frames. A DMG STA obtains the operational parameters in use by its AP or PCP through the DMG Operation Information field of the DMG Operation

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

element. A DMG STA shall update the value of its local MIB attributes with the corresponding field value transmitted by its AP or PCP within the DMG BSS Parameter Configuration field of the DMG Operation element (9.4.2.126.7). Except for the prefix "dot11" used in the MIB attribute naming convention, the name of the field is the same as the name of the corresponding MIB attribute.

11.1.4.6 Operation of Supported Rates and BSS Membership Selectors element and Extended Supported Rates and BSS Membership Selectors element

The Supported Rates and BSS Membership Selectors element and Extended Supported Rates and BSS Membership Selectors element in Beacon and Probe Response frames is used by STAs in order to avoid joining a BSS if they do not support all of the data rates in the BSSBasicRateSet parameter or all of the BSS membership requirements in the BSSMembershipSelectorSet parameter.

A STA shall include the rates from its OperationalRateSet parameter and the rates from the BSSBasicRateSet parameter and the BSS membership selectors from the BSSMembershipSelectorSet parameter in frames it transmits containing Supported Rates and BSS Membership Selectors elements and Extended Supported Rates and BSS Membership Selectors elements according to the rules described in this subclause with the following exceptions:

1) A non-AP STA may omit the HT and VHT BSS membership selectors, as the (V)HT capabilities are indicated through the presence of a (V)HT Capabilities element.
2) An S1G or CMMG STA should not include supported rates in frames it transmits since its MCS capabilities are indicated in its Capabilities element. An S1G or CMMG STA should ignore supported rates in frames it receives since the peer's MCS capabilities are indicated in its Capabilities element.

NOTE 1—Rates are expressed in units of 500 kb/s, up to 63.5 Mb/s (see 9.4.2.3). This might result in duplicate values for an S1G STA, and in values that cannot be expressed for a CMMG STA.

For a STA that supports a combined total of eight or fewer data rates and BSS membership selectors the Extended Supported Rates and BSS Membership Selectors element is optional, and may be included in all of the frame types that include the Supported Rates and BSS Membership Selectors element.

A STA that supports a combined total of the number of rates in the OperationalRateSet parameter and the number of BSS membership selectors that exceeds eight shall include an Extended Supported Rates and BSS Membership Selectors element to specify the supported rates and BSS membership selectors that are not included in the Supported Rates and BSS Membership Selectors element.

If the BSSMembershipSelectorSet parameter contains at least one BSS membership selector, then the STA shall include at least one BSS membership selector value from the BSSMembershipSelectorSet parameter in the Supported Rates and BSS Membership Selectors element.

NOTE 2—Inclusion of at least one BSS membership selector in the Supported Rates and BSS Membership Selectors element causes a receiving STA that was implemented before the existence of the Extended Supported Rates and BSS Membership Selectors element to still receive at least one BSS membership selector, which it will consider to be a basic rate that it does not support, and therefore it will not associate to the BSS.

Upon receipt, the Supported Rates and BSS Membership Selectors element in Beacon and Probe Response frames is delivered to the management entity in a STA via the BSSBasicRateSet parameter in the MLME-SCAN.confirm primitive. The BSS membership selector information in Beacon and Probe Response frames is delivered to the management entity in a STA via the BSSMembershipSelectorSet parameter in the MLME-SCAN.confirm primitive. Together, these parameters are used by the management entity in a STA to avoid joining a BSS if the STA cannot receive and transmit all of the data rates in the BSSBasicRateSet parameter or does not support all of the features represented in the BSSMembershipSelectorSet parameter.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA that is implemented after the existence of the BSSMembershipSelectorSet parameter includes each octet of the Supported Rates and BSS Membership Selectors element that is encoded with the MSB (bit 7) equal to 1 and that it does not recognize as a rate in its BSSMembershipSelectorSet parameter. The STA then determines if it can support all of the features represented in its BSSMembershipSelectorSet parameter before attempting to join the network. If some BSSMembershipSelectorSet parameter values are not recognized by the STA, the STA does not attempt to join the network.

NOTE 3—STA that was implemented before the existence of the BSSMembershipSelectorSet parameter interprets each BSS membership selector in the Supported Rates and BSS Membership Selectors element as though it were a rate from the BSSBasicRateSet parameter. These values of BSS membership selectors will not match a rate that is known to the STA and, therefore, the management entity in the STA will not associate with the BSS, because it will determine that the STA cannot receive or transmit at what appears to be a required rate.

11.1.4.7 DMG discovery outside the context of a BSS

This subclause applies to a DMG STA when dot11DMGOCBActivated is true.

Upon receipt of the MLME-DMG-OCB-START.request primitive, a DMG STA continuously discovers new peer STAs. If the discovery beacon parameter is equal to true, the STA shall start transmitting DMG Beacon frames with the Discovery Mode field set to 1, the OCB subfield in the Clustering Control field set to 1, and the Beacon Interval field set to a random value as described in 11.1.3.4. If the discovery beacon parameter is equal to false, the DMG STA shall not transmit DMG Beacon frames.

When the STA receives one or more SSW frames with the OCB subfield equal to 1 during an A-BFT or DTI and completes SLS with the peer STA, and the address of the peer STA is an address that is newly discovered, the STA shall issue an MLME-OCB-DMGDISCOVERY.indication with the PeerInfoSet parameter including the PeerInfo vector for the peer STA that transmitted the SSW frame. Each PeerInfo vector consists of the parameters shown in Table 11-3, in which the term peer STA refers to the STA that transmitted the received DMG Beacon frame, SSW frame, SSW Feedback frame, or SSW Ack frame.

Table 11-3—PeerInfo vectors

Name	Type	Valid range	Description
PeerSTAAddress	MAC address	Any valid individual MAC address	Specifies the MAC address of the discovered peer STA.
Sector sweep	As defined in frame format	As defined in 9.3.4.2	The values from the Sector Sweep field from the DMG Beacon frame, else null.
Sector sweep feedback	As defined in frame format	As defined in 9.5.3	The values from the Sector Sweep field from the SSW, SSW Feedback, or SSW Ack frame, else null.
DMG parameters	As defined in frame format	As defined in 9.3.4.2	The values from the DMG Parameters field from the DMG Beacon frame, else null.
DMG capabilities	As defined in frame format	As defined in 9.4.2.127	The values from the DMG Capabilities element if such an element was present in the DMG Beacon frame, else null.
EDMG capabilities	As defined in frame format	As defined in 9.4.2.265	Specifies the parameters within the EDMG Capabilities element that are supported by the MAC entity.

When the STA receives one or more DMG Beacon frames with the OCB subfield equal to 1 from a peer STA, and the address of the peer STA is an address that is newly discovered, the STA shall perform an SLS with the OCB subfield set to 1 in transmitted SSW frames during the A-BFT following the DMG Beacon frames or the DTI. If the SLS is completed, the STA shall issue an MLME-OCB-DMGDISCOVERY.indication with the PeerInfoSet parameter including the PeerInfo for the peer STA that transmitted the DMG Beacon frame.

When the STA completes SLS with a peer STA that transmitted an SSW frame with the OCB subfield equal to 1 or a DMG Beacon frame with the OCB subfield equal to 1, and the address of the peer STA is not an address that is newly detected, the STA may issue an MLME-OCB-DMGDISCOVERY.indication with the PeerInfoSet parameter including the PeerInfo regarding the peer STA.

Upon receipt of the MLME-DMG-OCB-STOP.request primitive, a DMG STA shall terminate transmission of DMG Beacon frames and cease discovery of peer STAs.

Figure 11-14 illustrates an example of the DMG discovery outside the context of a BSS, in which the discovery beacon parameter is equal to true in the MLME-DMG-OCB-START.request primitive for both STAs.

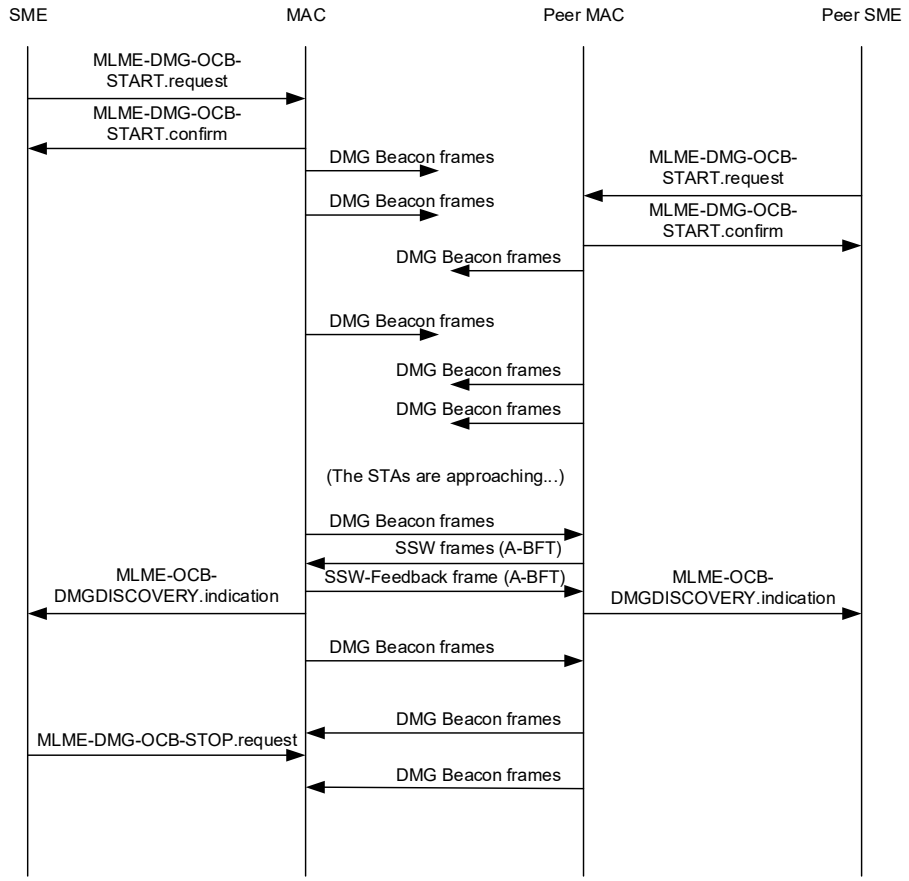

Figure 11-14—DMG discovery outside the context of a BSS

Figure 11-15 illustrates an example of beamforming training during the DMG discovery outside the context of a BSS, in which the MAC address of the peer STA is informed over a higher layer and included in the MLME-BF-TRAINING.request primitive.

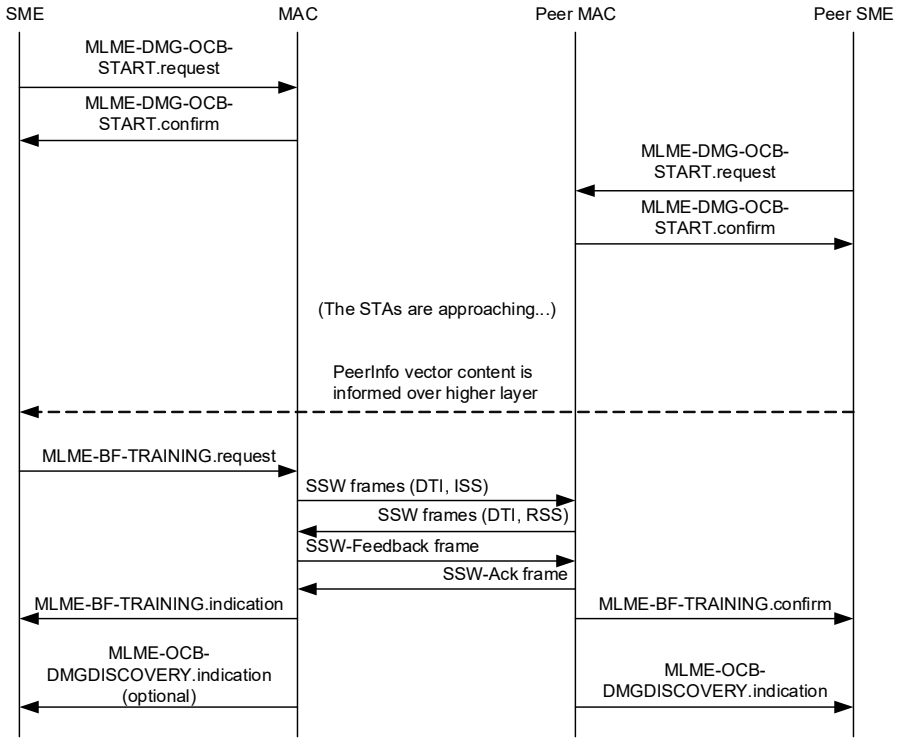

Figure 11-15—Beamforming training during the DMG discovery outside the context of a BSS

11.1.5 Adjusting STA timers

A STA in an infrastructure BSS or PBSS shall adopt the TSF timer value in a Beacon, S1G Beacon, Probe Response, PV1 Probe Response, DMG Beacon, or Announce frame transmitted by the BSS's AP or PCP. The STA shall use the algorithm specified in 11.1.3.9.

To response to an MLME-JOIN.request primitive, a STA joining an IBSS shall initialize its TSF timer to 0 and shall not transmit a Beacon, S1G Beacon, Probe Response, PV1 Probe Response, or DMG Beacon frame until it receives from a member of the IBSS a Beacon, S1G Beacon, Probe Response, PV1 Probe Response, or DMG Beacon frame that has a matching SSID. Consequently, the STA joining an IBSS adopts the timer from the next Beacon, S1G Beacon, Probe Response, PV1 Probe Response, or DMG Beacon frame from its IBSS.

A STA receiving a Beacon, S1G Beacon, Probe Response, PV1 Probe Response, DMG Beacon, or Announce frame from another IBSS STA with the same SSID shall compare the Timestamp field with its own TSF time. If the Timestamp field of the received frame is later than its own TSF timer, a STA that is neither a DMG nor an S1G STA in the IBSS shall adopt all parameters contained in the Beacon frame according to the rule for that parameter found in the IBSS adoption column of the matching row of the BSSDescription table found in 6.5.3.3.2. An S1G STA shall adopt all parameters contained in the S1G Beacon frame according to the rule for that parameter found in IBSS adoption column of the matching row of the BSSDescription table found in 6.5.3.2.2 if the Timestamp field of the received frame is later than its own TSF timer and the TSF Completion field in the S1G Beacon Compatibility element is not less than the value of the 4 most significant octets of its own TSF timer. A DMG IBSS STA shall adopt each parameter contained in the DMG Beacon or Announce frames. Parameters adopted by a STA due to the receipt of a later timestamp shall not be changed by

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the STA except when adopting parameters due to a subsequently received Beacon, S1G Beacon, DMG Beacon, or Announce frame with a later timestamp.

11.1.6 Terminating a BSS

At any time an infrastructure BSS or PBSS may be terminated. At any time a STA may cease support for an IBSS that it formed. Upon receipt of an MLME-STOP.request primitive, a STA shall stop transmitting Beacon, S1G Beacon, Probe Response, PV1 Probe Response, DMG Beacon, and Announce frames and deauthenticate all associated STAs.

11.1.7 TDD time synchronization

This subclause applies to DMG STAs that are operating under TDD channel access (see 10.38.6.2.2 (SP with TDD channel access)) and that have the TDD Synchronization Mode subfield in their DMG Capabilities element equal to 1.

All STAs shall include a TDD Synchronization element, at least once per beacon interval, in transmitted Announce frames. An AP or PCP may include a TDD Synchronization element in DMG Beacon frames.

NOTE 1—A STA is not required to transmit the TDD Synchronization element during a beacon interval where it does not have transmit opportunity, subject to TDD channel access rules, to transmit an Announce frame.

A STA with dot11DMGTDDLocalClockModeActivated set to true shall not update its TSF timer based on the Timestamp field of a received DMG Beacon or Announce frame.

A STA with dot11DMGTDDLocalClockModeActivated set to false shall update its TSF timer based on the Timestamp field of each received DMG Beacon or Announce frame that includes a TDD Synchronization element with the Sync Mode field set to 0, unless both of the following are true:

— The last frame the STA used to update its TSF timer was a frame received in the same beacon interval as the new frame.
— The Clock Attributes field in the TDD Synchronization element of that last frame scores better than the Clock Attributes field in the TDD Synchronization element of the new frame. The logic to compare two Clock Attributes field values is the same as the logic to compare two IEEE 802.1AS systemIdentity attributes, as defined in 8.6.2 in IEEE Std 802.1AS-Rev/D8.0.

NOTE 2—While the comparison metric and logic are defined the same as IEEE 802.1AS for flexibility, using the IEEE 802.1AS protocol for TDD time synchronization is not required and is beyond the scope of this standard. The logic to compare two Clock Attributes field values is a hierarchical comparison of the Clock Attributes subfields in this order: Priority 1, Clock Class, Clock Accuracy, Offset Scaled Log Variance, and Priority 2, with a lower numeric value for each subfield indicating a better clock.

If a STA with dot11DMGTDDLocalClockModeActivated set to false receives an Announce frame that has the Sync Mode field in the TDD Synchronization element equal to 1, then the SME of the STA shall issue an MLME-DISASSOCIATE.request primitive with ReasonCode parameter set to TIME_SYNC_LOST and PeerSTAAddress parameter set to the TA of the received Announce.

11.2 Power management

11.2.1 General

A non-AP STA can be in one of two power management modes:

— Active mode: The STA receives and transmits frames at any time if the STA is in awake state. A non-HE STA remains in the awake state. An HE STA remains in the awake state, unless the STA is

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

unavailable. A STA that is unavailable is not capable of receiving PPDUs. A STA is permitted to be unavailable as described in 26.14.3, 26.14.1, and 26.8.4.4.

— Power save (PS) mode: The STA enters the awake state to receive or transmit frames. The STA remains in the doze state otherwise.

A STA in PS mode can be in one of two power states:

— Awake: STA is fully powered.

— Doze: STA is not able to transmit or receive non-WUR PPDUs and consumes very low power.

The manner in which a STA transitions between power states is determined by its power management mode and reflected in dot11PowerManagementMode.

The power management mode of a STA is selected by the PowerManagementMode parameter of the MLME-POWERMGT.request primitive or MLME-MESHPOWERMGT.request primitive. Once the STA updates its power management mode, the MLME shall issue an MLME-POWERMGT.confirm primitive or MLME-MESHPOWERMGT.confirm primitive respectively indicating the success of the operation.

When MSDUs or A-MSDUs are buffered for power management purposes, the information in the MAC service tuple(s) for the MSDU(s) shall be maintained (and reordered) as a unit.

11.2.2 Bufferable MMPDUs

MMPDUs are categorized as bufferable or nonbufferable, as shown in Table 11-4. Bufferable MMPDUs are eligible to be queued for delivery using a power-saving mechanism.

Nonbufferable MMPDUs are delivered without reference to a power saving mechanism.

Table 11-4—Bufferable/nonbufferable classification of MMPDUs

Description	Classification
An MMPDU that is carried in one or more Action (except for FTM frame and FTMR frame), Disassociation, or Deauthentication frame	Bufferable
An individually addressed MMPDU that is carried in one or more Probe Response frames and that is sent in an IBSS in response to an individually addressed Probe Request frame.	Bufferable
All other MMPDUs.	Nonbufferable

11.2.3 Power management in a non-DMG infrastructure network

11.2.3.1 General

A STA that is associated with an AP and that changes power management mode shall inform the AP of this fact using the Power Management subfield within the Frame Control field of transmitted frames. The STA shall remain in its current power management mode until it informs the AP of a power management mode change via a frame exchange sequence that includes an acknowledgment from the AP. Power management mode shall not change during any single frame exchange sequence.

NOTE 1—This means the Power Management subfield is the same for all MPDUs in an A-MPDU.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The AP shall buffer individually addressed BUs addressed to STAs operating in a PS mode. These buffered BUs shall be transmitted only at designated times.

If any non-GLK STA in its BSS is in PS mode, the AP shall buffer all non-GCR-SP group addressed BUs that arrive via the DS and deliver them to all non-GLK STAs immediately following the next DTIM beacon. If the AP is an S1G AP, the AP may additionally deliver these BUs using group AID as defined in 10.54. If any GLK STA in its BSS is in PS mode, the AP shall not include any such STAs as a SYNRA destination and shall buffer all group addressed BUs that arrive from the attached bridge and are destined to such STAs, delivering them with individually addressed MPDUs using power save delivery methods.

NOTE 2—The group addressed buffered BUs containing one or more MSDUs for GLK type STAs and for non-GLK type STAs are not repeated by the AP to the other type of STA. Network entities external to the AP, such as the bridged network, may repeat these MSDUs to both types of STAs by other means, outside the scope of this standard.

An S1G AP with dot11NDPPSPollSupport equal to true shall set the NDP PS-Poll Supported field in the S1G Capabilities element to 1. Otherwise it shall set the NDP PS-Poll Supported field in the S1G Capabilities element to 0.

The STAs that currently have buffered BUs (excluding those BUs for a STA associated with ACs that are U-APSD delivery-enabled when not all ACs are delivery-enabled by that STA) within the AP are identified in a TIM, which shall be included as an element within all Beacon frames generated by the AP. A STA shall determine that a BU is buffered for it by receiving and interpreting a TIM.

In a non-S1G STA, the traffic-indication virtual bitmap, maintained by the AP, shall be transmitted in a TIM element. In an S1G STA, the traffic-indication virtual bitmap may be divided into more than one page and each page shall be transmitted in a TIM element, hence, more than one TIM element may appear in an S1G Beacon frame. If more than one TIM element is present, then the TIM elements shall be ordered based on the Page Index and Page Slice Number subfields in the Bitmap Control field. TIM elements with Page Slice Number field equal to 31 (if any) shall be the first ones and ordered from page 0 to page 3, and may be followed by TIM elements (if any when Page Slicing is supported) with Page Slice Number field from 0 to 30 each of which shall also be ordered from page 0 to page 3. In an S1G STA, the traffic virtual bitmap shall be encoded as defined in 9.4.2.5 (TIM element) where the ADE mode may be used by the AP only if the TIM ADE Support field in the S1G Capabilities element received from every STA with AID included in the TIM element, is 1. Otherwise ADE mode shall not be used to encode the TIM element.

A STA operating in PS mode with dot11NonTIMModeActivated equal to false that is not in WNM sleep mode shall periodically listen for Beacon frames, as determined by the ListenInterval parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive and the ReceiveDTIMBeacons parameter of the MLME-POWERMGT.request primitive. STAs operating in PS modes with dot11NonTIMModeActivated equal to true transmit at least one PS-Poll or trigger frame that is individually addressed to the associated AP every ListenInterval parameter used by the MLME primitives starting from the last known transition of the S1G STA in non-TIM mode in doze state unless it follows the TWT or NDP Paging procedure.

WNM sleep mode enables an extended power save mode for non-AP STAs in which a non-AP STA need not listen for every DTIM beacon, and need not perform GTK/IGTK/BIGTK updates. STAs in WNM sleep mode can transition to awake state as infrequently as once every WNM sleep interval to check whether the corresponding TIM bit is set or group addressed traffic is pending.

NOTE 3—A STA might use both WNM sleep mode and PS mode simultaneously.

If an S1G AP with dot11NDPPSPollSupport equal to true has a buffered BU for a STA associated with the AP and receives an NDP PS-Poll frame from the STA, it should send the buffered BU with the MCS level that is calculated based on the value indicated in the Preferred MCS subfield in the received NDP PS-Poll frame

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

unless the indicated MCS level violates rate selection rule for Data frames (as defined in 10.6.5 (Rate selection for Data and Management frames)).

The Power Management subfield of the Frame Control field may be set to 0 or 1 within a frame sent by a STA in WNM sleep mode.

When a STA is in WNM sleep mode and in PS mode, the AP buffers individually addressed frames according to the traffic filtering agreement established between the AP and STA, as specified in 11.21.12.2. When a STA is in WNM sleep mode but not in PS mode, the traffic filtering agreement between the AP and STA and the timer for the WNM sleep interval remain in place, and the AP queues for nonbuffered delivery all matched frames (i.e., matched by the traffic filtering agreement) destined to the STA.

In a BSS operating under the DCF or EDCA, upon determining that a BU is currently buffered in the AP, a STA operating in the normal (non-APSD) PS mode transmits a (NDP) PS-Poll frame to the AP, which responds with the corresponding buffered BU immediately, or acknowledges the (NDP) PS-Poll frame and responds with the corresponding BU at a later time.

An S1G STA may transmit NDP PS-Poll frames instead of PS-Poll frames to an S1G AP from which it has received a frame containing an S1G Capabilities element with the NDP PS-Poll Supported field equal to 1; otherwise, the S1G STA shall not transmit NDP PS-Poll frames. If an S1G STA detects that the partial BSSID of the BSS of which it is a member is equal to the partial BSSID of another BSS from which it receives frames, then the S1G STA shall not transmit NDP PS-Poll frames to its associated AP to avoid ambiguity. A non-S1G STA shall not transmit NDP PS-Poll frames. An S1G STA shall set the Poll Type subfield in the Frame Control field of the transmitted PS-Poll(+BDT) frame to 0 unless it is an S1G STA in non-TIM mode that follows the procedure described in 10.47.2. An S1G STA in TIM mode shall not send a PS-Poll with the Poll Type subfield equal to 1.

A non-AP QoS STA may be in PS mode before the setup of block ack. BUs for a TID without a schedule are sent using Normal Ack following a PS-Poll frame as described in rest of 11.2.3 (Power management in a non-DMG infrastructure network). Uplink block ack agreements, block ack agreements for any TID with a schedule, and any block ack agreements to APSD STAs continue to operate normally.

NOTE 4—When a STA is in normal (non-APSD) PS mode, the rules described in 11.2.3.6 for PS-Poll operation apply to any downlink block ack agreement without an associated schedule. An (A-)MSDU delivered for this block ack agreement in response to the PS-Poll frame might be delivered in an A-MPDU. At most one (A-)MSDU is delivered.

An S1G AP may change its Power Management mode as described in 11.2.3.17.

An S1G STA in PS mode shall set the More Data field to 1 in a frame transmitted to its AP when the STA intends to transmit another frame to the AP within this SP. An S1G STA in PS mode shall set the More Data field to 0 in a frame transmitted to its AP when the STA does not intend to transmit another frame to the AP within this SP.

11.2.3.2 Non-AP STA power management modes

A non-AP STA shall be in active mode upon (re)association, except that if the (re)association is performed using the on-channel tunneling procedure defined in 11.31.5, then the non-AP STA shall be considered to be in power save mode and in doze state upon (re)association on the BSS identified by the BSSID, Band ID, and Channel Number fields contained in the Multi-band element transmitted in the On-channel Tunnel Request frame that carries the (Re)Association Request frame.

A STA that has transmitted a frame to an AP with which it is not associated and from which it expects a response shall remain in the awake state until such a response is received or until the procedure has timed out.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

To change power management modes a STA shall inform the AP by completing a successful frame exchange that is initiated by the STA. This frame exchange sequence shall include a Management frame, Extension frame or Data frame from the STA, and an Ack or a BlockAck frame from the AP. The Power Management subfield(s) in the Frame Control field of the frame(s) sent by the STA in this exchange indicates the power management mode that the STA shall adopt upon successful completion of the frame exchange sequence, except where the Power Management subfield is reserved (see 9.2.4.1.7). A non-AP STA shall not change power management mode using a frame exchange sequence that does not receive an Ack or BlockAck frame from the AP, or using a BlockAckReq frame.

NOTE 1—A PS-Poll frame exchange sequence does not necessarily result in an Ack frame from the AP, so a non-AP STA cannot change power management mode using a PS-Poll frame.

NOTE 2—The Power Management subfield is ignored in frame exchange sequences initiated by the AP.

A non-S1G STA that is changing from doze to awake state in order to transmit shall perform CCA until a frame is detected by which it can set its NAV, or until a period of time indicated by the NAVSyncDelay from the MLME-JOIN.request primitive has transpired. An S1G STA that is changing from doze to awake state in order to transmit shall perform CCA until a frame is detected by which it can set its RID or NAV, or until a period of time indicated by the NAVSyncDelay from the MLME-JOIN.request primitive has transpired.

To change power management mode, a STA that is coordinated by an MM-SME shall inform the AP through a successful frame exchange sequence initiated by the STA. The Power Management subfield in the Frame Control field of the frame sent by the STA in this exchange indicates the power management mode that the STAs coordinated by the MM-SME and advertised in the MMS element sent by the STA shall adopt upon successful completion of the frame exchange sequence. To change the power management mode of the coordinated STA, the frame may be sent using any of the MMSLs within the MMSL cluster established with the AP.

An S1G AP that sets the STA Type Support in transmitted S1G Capabilities elements to 0 or 1 shall set dot11NonTIMModeActivated to true and the Non-TIM Support field in the S1G Capabilities element to 1. An S1G AP that sets the STA Type Support in transmitted S1G Capabilities elements to 2 may set dot11NonTIMModeActivated to false and the Non-TIM Support field in the S1G Capabilities element to 0. An S1G AP that sets the STA Type Support in transmitted S1G Capabilities elements to 2 may set dot11NonTIMModeActivated to true and the Non-TIM Support field in the S1G Capabilities element to 1.

An S1G AP shall not set the Non-TIM Support field to 1 in response to a non-TIM Support field equal to 0.

An S1G AP that includes an AID Response element in a (Re)Association Response frame shall set the AID/Group AID field to the AID assigned to the (re)associating STA, the AID Switch Count field to 0, and the AID Response Interval field to the Listen Interval field.

NOTE 3—The S1G AP can specify a listen interval that is different from the listen interval requested by the non-AP S1G STA in the (Re)Association Request frame if the AP cannot buffer the S1G STA's BUs for the requested listen interval.

A non-AP S1G STA requests the type of PS mode (TIM mode or non-TIM mode) through the (Re)Association Request frame transmitted to the S1G AP.

A non-AP S1G STA requests operation in non-TIM mode by setting the Non-TIM Support field in the S1G Capabilities element in the (Re)Association Request frame to 1.

A non-AP S1G STA requests operation in TIM mode by setting the Non-TIM Support field in the S1G Capabilities element in the (Re)Association Request frame to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A non-AP S1G STA determines the type of PS mode (TIM mode or non-TIM mode) from the (Re)Association Response frame received from the S1G AP.

If an S1G AP sets the Non-TIM Support field in the S1G Capabilities element in the (Re)Association Response frame to 1, then the non-AP S1G STA shall set dot11NonTIMModeActivated to true and operate in non-TIM mode following association, and is referred to as a non-TIM STA.

If an S1G AP sets the Non-TIM Support field in the S1G Capabilities element in the (Re)Association Response frame to 0, then the non-AP S1G STA shall set dot11NonTIMModeActivated to false and operate in TIM mode following association, and is referred to as a TIM STA.

A non-AP S1G STA shall operate in the negotiated PS mode during association unless a PS mode switch is negotiated as described in 10.20 or a temporary PS mode switch has occurred as described in 10.47.2. The STA shall update the value of the ListenInterval parameter it uses in invocations of primitives with the AID Response Interval field in the AID Response element of the (Re)Association Response frame.

An S1G STA in TIM mode listens to selected Beacon frames (based upon the ListenInterval parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive) and sends PS-Poll frames to the AP if the TIM element in the most recent Beacon frame indicates an individually addressed BU is buffered for that STA.

An S1G STA in non-TIM mode shall transmit at least one PS-Poll or trigger frame that is individually addressed to the associated AP every listen interval and might not listen to selected S1G Beacon frames (based upon the ListenInterval parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive) unless it follows the TWT or NDP Paging procedure. An S1G STA in non-TIM mode may send (NDP) PS-Poll frames to an S1G AP regardless of whether individually addressed buffered BUs have been indicated by the S1G AP.

11.2.3.3 AP TIM transmissions

The TIM shall identify the STAs for which traffic is pending and buffered in the AP. This information is coded in a *partial virtual bitmap*, as described in 9.4.2.5. In addition, the TIM contains an indication whether non-SYNRA group addressed traffic is pending. Every STA is assigned an AID by the AP as part of the association process. AID 0 is reserved to indicate the presence of buffered non-GCR-SP group addressed BUs to be delivered using MPDUs with an RA other than a SYNRA but that are not delivered using group AID. The AP shall identify those STAs for which it is prepared to deliver[43] buffered BUs by setting bits in the TIM's partial virtual bitmap that correspond to the appropriate AIDs.

NOTE—AID 0 is signaled in the Traffic Indicator field when the DTIM Count field is zero.

For an S1G band, the TIM is coded in an S1G partial virtual bitmap, as described in 9.4.2.5. This information is constructed with one of the four encoding modes: the Block Bitmap mode, the Single AID model, the OLB (offset, length, bitmap) mode, and the ADE (AID with differential encoding) mode. An S1G AP shall not transmit the TIM with the encoding mode in the Block Control subfield set to ADE mode to another S1G STA unless the TIM ADE Support field of the S1G Capabilities element received from that STA contained a value of 1 and dot11TIMADEImplemented is true.

[43] How the AP or mesh STA determines the traffic it is prepared to deliver is outside the scope of this standard.

11.2.3.4 TIM types

Two different TIM types are distinguished: TIM and DTIM. After a DTIM beacon, the AP shall transmit buffered non-GCR-SP group addressed BUs to be delivered using MPDUs with an RA other than a SYNRA, before transmitting any individually addressed frames. The AP may additionally deliver these BUs using group AID as defined in 10.54.

The AP shall transmit a TIM with every Beacon frame except when the frame is scheduled for transmission in a TSBTT that is not a TBTT. Every dot11DTIMPeriod, a TIM of type DTIM is transmitted within a Beacon frame, rather than an ordinary TIM. An S1G AP with dot11ShortBeaconInterval equal to true may include a TIM in a Beacon frame that is scheduled for transmission in a TSBTT that is not a TBTT. An S1G AP with dot11ShortBeaconInterval equal to true may transmit a TIM of type DTIM in an S1G Beacon frame every dot11ShortBeaconDTIMPeriod.

Figure 11-16 illustrates the AP and STA activity under the assumption that a DTIM beacon is transmitted once every three TIMs. The top line in Figure 11-16 represents the time axis, with the beacon interval shown together with a DTIM Interval of three beacon intervals. The second line depicts AP activity. The AP schedules Beacon frames for transmission every beacon interval, but the Beacon frames may be delayed if there is traffic at the TBTT. This is indicated as “busy medium” on the second line. For the purposes of this figure, the important fact about Beacon frames is that they contain TIMs, some of which are DTIM beacons. Note that the second STA with ReceiveDTIMBeacons equal to false does not power-on its receiver for all DTIM beacons.

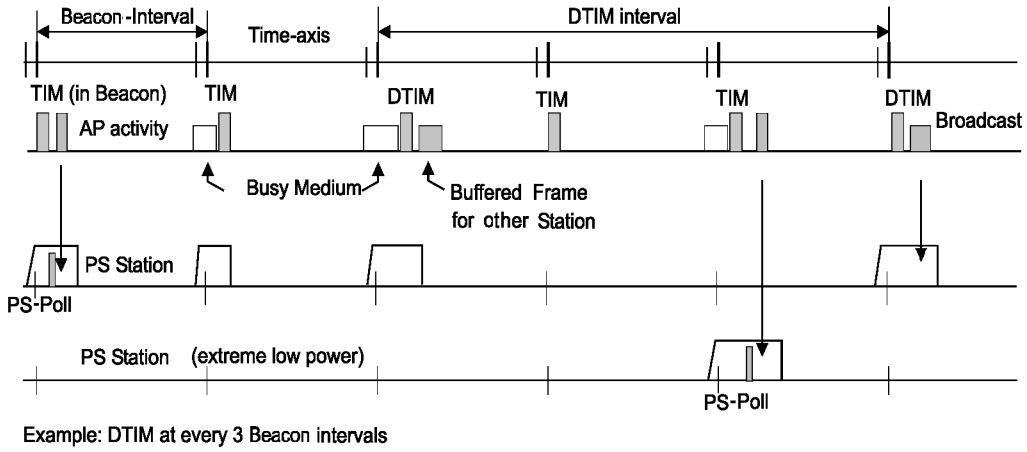

Figure 11-16—Infrastructure power management operation

The third and fourth lines in Figure 11-16 depict the activity of two STAs operating with different power management requirements. Both STAs power-on their receivers when they need to listen for a TIM. This is indicated as a rampup of the receiver power prior to the TBTT. The first STA, for example, powers up its receiver and receives a TIM in the first Beacon frame; that TIM indicates the presence of a buffered BU for the receiving STA. The receiving STA then generates a PS-Poll frame, which elicits the transmission of the buffered BU from the AP. Non-GCR-SP group addressed BUs are sent by the AP subsequent to the transmission of a DTIM beacon.

11.2.3.5 Power management with APSD

11.2.3.5.1 Power management with APSD procedures

QoS APs capable of supporting automatic power save delivery (APSD) shall signal this capability through the use of the APSD subfield in the Capability Information field in Beacon, Probe Response, and (Re)Association Response frames.

QoS STAs use the Power Management subfield in the Frame Control field of a frame to indicate whether it is in active or PS mode. As APSD is a mechanism for the delivery of BUs to power saving STAs, the frames transmitted by a STA in PS mode that is using APSD have the Power Management subfield in the Frame Control field set to 1, thereby causing buffering to take place at the AP.

APSD defines two delivery mechanisms, namely *unscheduled APSD* (U-APSD) and *scheduled APSD* (S-APSD). STAs may use U-APSD to have some or all of their BUs delivered during unscheduled SPs. STAs may use S-APSD to schedule delivery of some or all of their BUs during scheduled SPs.

If there is no unscheduled SP in progress, the unscheduled SP begins when the AP receives a trigger frame from a STA, which is a QoS Data or QoS Null frame using an AC the STA has configured to be trigger-enabled. An A-MPDU that contains one or more trigger frames acts as a trigger frame. An unscheduled SP ends after the AP has attempted to transmit at least one BU using a delivery-enabled AC and destined for the STA, but no more than the number indicated in the Max SP Length field of the QoS Capability element of the STA's (Re)Association Request frame if the field has a nonzero value.

NOTE 1—The transmission of one or more fragments of a BU counts as the transmission of one BU for the purposes of the constraint indicated by the Max SP Length field.

The last frame sent during the SP has the EOSP subfield set to 1. An unscheduled SP may be terminated before the maximum number of BUs in the SP has been reached. The times at which an AP may transmit during an unscheduled SP might be constrained by the U-APSD coexistence mechanism (see 11.2.3.5.2).

In order to configure an AP to deliver BUs during an unscheduled SP, a STA designates one or more of its ACs to be delivery-enabled and one or more of its AC to be trigger-enabled. A STA may configure an AP to use U-APSD using two methods. First, the STA may set individual U-APSD Flag bits in the QoS Info subfield of the QoS Capability element carried in (Re)Association Request frames. When a U-APSD Flag bit is 1, it indicates that the corresponding AC is both delivery- and trigger-enabled. When all four U-APSD Flag subfields are equal to 1 in (Re)Association Request frames, all of the ACs associated with the STA are trigger- and delivery-enabled during (re)association. When all four U-APSD Flag subfields are equal to 0 in (Re)Association Request frames, none of the ACs associated with the STA is trigger- or delivery-enabled during (re)association.

Alternatively, the STA may designate one or more AC as trigger-enabled and one or more AC as delivery-enabled by sending an ADDTS Request frame per AC to the AP with the APSD subfield set to 1 and the Schedule subfield set to 0 in the TS Info field in the TSPEC element. APSD settings in a TSPEC request take precedence over the static U-APSD settings carried in the QoS Capability element. In other words, a TSPEC request overwrites any previous U-APSD setting of an AC.

NOTE 2—Such an ADDTS Request frame can be sent regardless of the ACM setting of the AC.

A STA may set an AC to be trigger- or delivery-enabled for its own use by setting up TSPECs with the APSD subfield set to 1 and the Schedule subfield set to 0 in the uplink or downlink direction, respectively. An uplink TSPEC plus a downlink TSPEC, or a bidirectional TSPEC with the APSD subfield equal to 1 and the Schedule subfield equal to 0, makes an AC both trigger- and delivery-enabled. An uplink TSPEC plus a downlink TSPEC, or a bidirectional TSPEC with the APSD and the Schedule subfields both equal to 0, makes an AC neither trigger- nor delivery-enabled.

A scheduled SP starts at fixed intervals of time specified in the Service Interval field.The following rules describe scheduled SP operation:

a) If the scheduled Service Interval field equals 0 (for example, with the GCR-A delivery method), the scheduled SP starts from the service start time without a fixed delivery interval.

b) To use a scheduled SP for a TS when the access policy is controlled channel access, a STA shall send an ADDTS Request frame to the AP with the APSD subfield of the TS Info field in the TSPEC element set to 1.

c) To use a scheduled SP for a TS for an AC when the access policy is contention based channel access, a STA shall send an ADDTS Request frame to the AP with the APSD and Schedule subfields of the TS Info field in the TSPEC element both set to 1. If the APSD mechanism is supported by the AP and the AP accepts the corresponding ADDTS Request frame from the STA, the AP shall respond to the ADDTS Request frame with a response containing the Schedule element indicating that the requested service can be accommodated by the AP.

d) When the access policy is contention based channel access for a GCR group addressed stream, a scheduled SP is set up according to 11.21.16.3.3. The first scheduled SP starts when the lower order 4 octets of the TSF timer equals the value specified in the Service Start Time field.

e) If the SI is nonzero, a STA using scheduled SP shall first transition to awake state at the service start time to receive downlink individually addressed and/or GCR-SP group addressed BUs buffered and/or to receive polls from the AP or HC. The STA shall transition to awake state subsequently at a fixed time interval equal to the SI.

f) The AP may modify the non-GCR service start time by indicating so in the Schedule element in a successful ADDTS Response frame (which is sent in response to an ADDTS Request frame) and in Schedule frames (which are sent at other times).

g) The AP may modify the GCR service start time by indicating so in the Schedule element in the GCR Response subelements (see 9.4.2.87 and 11.21.16.3.4).

h) In both non-GCR and GCR cases, the service start time shall be updated (using the previously described service start time modification procedures) whenever the upper 4 octets of the TSF timer change.

A scheduled SP begins at the scheduled wakeup time that corresponds to the SI and the service start time indicated in the Schedule element sent in response to a TSPEC or GCR Request. If the SI is nonzero, the STA shall transition to awake state at a subsequent time when the following is true:

$$(TSF - T_{service\text{-}start}) \bmod SI_{min} = 0$$

where

$T_{service\text{-}start}$ is the service start time
SI_{min} is the minimum SI

If the SI is nonzero, a scheduled SP for a GCR group ends after the AP has attempted to transmit at least one BU associated with the GCR group but no more than the number indicated in the Max SP Length field of the QoS Capability element of the STA's (Re)Association Request frame. The last frame of the GCR SP shall have the EOSP subfield set to 1.

NOTE 3—The transmission of one or more fragments of a BU counts as the transmission of one BU for the purposes of the constraint indicated by the Max SP Length field.

If a scheduled SP overlaps the period during which the AP is required to transmit non-GCR-SP group addressed frames and individually addressed frames to STAs in PS mode that follow a DTIM beacon that has at least 1 bit set to 1 in the partial virtual bitmap of its TIM, the scheduled SP shall be deferred until the AP has transmitted all such buffered frames.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When the GCR-A delivery method is used, the scheduled Service Interval field is 0. If a STA has a GCR agreement with an AP for a group address using the GCR-A delivery method, there is no defined end of the scheduled SP. The STA in PS mode shall enter the awake state and shall remain awake in order to receive the buffered group addressed BUs until the AP changes the delivery method of the stream to a method other than GCR-A or until the GCR agreement is canceled.

If scheduled SPs are supported in a BSS, a STA may use both unscheduled and scheduled APSD on different ACs at the same time. The GCR-SP delivery method may be used on any AC, irrespective of any non-GCR unscheduled or scheduled APSD flows. When a STA establishes scheduled delivery for an AC the AP shall not transmit BUs using that AC during an SP that is initiated by a trigger frame, and it shall not treat BUs using the AC that are received from the STA as trigger frames.

APSD shall be used only to deliver individually addressed BUs and GCR-SP BUs to a STA. Non-GCR and non-GCR-SP group addressed BU delivery shall follow the frame delivery rules defined for group addressed BUs as defined in 11.2.3.6.

11.2.3.5.2 U-APSD coexistence

A non-AP STA that uses U-APSD might not be able to receive all AP transmitted frames during the service period due to interference observed at the non-AP STA. Although the AP might not observe the same interference, it is able to determine that the frames were not received correctly by the non-AP STA. The U-APSD coexistence capability enables the non-AP STA to indicate a requested transmission duration to the AP for use during U-APSD service periods. Use of the transmission duration enables the AP to transmit frames during the service period and improve the likelihood that the non-AP STA receives the frames when the non-AP STA is experiencing interference. The U-APSD coexistence capability reduces the likelihood that the AP transmits frames during the service period that are not received.

A STA with dot11UAPSDCoexistenceActivated equal to true shall support U-APSD coexistence and shall set to 1 the U-APSD Coexistence field of the Extended Capabilities elements that it transmits. Otherwise it shall set this field to 0.

A non-AP STA that is associated to an AP where both have previously advertised support for the U-APSD coexistence capability may transmit ADDTS Request frames including the U-APSD Coexistence element to the AP.

The content of the ADDTS Request frame excluding the U-APSD Coexistence element is referred to in subsequent text as the base ADDTS request. Upon reception of the ADDTS Request frame, the AP shall process the content of the base ADDTS request as described in 11.2.3.5. If the AP determines that the base ADDTS request cannot be granted it shall respond as described in 11.2.3.5, without processing the U-APSD Coexistence element. If the AP determines the base ADDTS request can be granted, it shall process the U-APSD Coexistence element. If the AP supports transmission of frames during the U-APSD service period for the duration value specified in the U-APSD Coexistence element Interval/Duration field, it shall grant the ADDTS request as described in 11.2.3.5. Otherwise, it shall deny the ADDTS Request.

If the AP has previously granted an ADDTS request with U-APSD coexistence, a non-AP STA that continues using QoS services provided by an ADDTS Request frame without U-APSD coexistence may terminate the use of U-APSD coexistence by transmitting an ADDTS Request frame without the U-APSD Coexistence element. A non-AP STA may terminate use of all QoS services (including U-APSD coexistence) resulting from an ADDTS Request frame by transmitting a DELTS Request frame to the AP.

The non-AP STA may transmit multiple ADDTS Request frames to the AP where the last received ADDTS Request frame overrides any previously received ADDTS Request frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An AP that supports U-APSD coexistence and accepts an ADDTS request limits the U-APSD coexistence service period according to the parameters specified in the ADDTS frame U-APSD Coexistence element, and shall transmit frames to the requesting non-AP STA according to the rules in 10.2.3.2 and the following rules:

— If the non-AP STA specified a nonzero TSF 0 Offset value in the U-APSD Coexistence element, the AP should not transmit frames to the non-AP STA outside of the U-APSD Coexistence Service Period, which begins when the AP receives the U-APSD trigger frame and ends after the transmission period specified by the result of the following calculation:

End of transmission period = *T* + (*Interval* – ((*T* – *TSF 0 Offset*) mod *Interval*))

where
T is the time the U-APSD trigger frame was received at the AP
Interval is the UAPSD Coexistence element Duration/Interval field value (see 9.4.2.89)

or upon the successful transmission of a frame with the EOSP subfield set to 1, whichever is earlier.

— If the non-AP STA specified a TSF 0 Offset value of 0 in the U-APSD Coexistence element, the AP should not transmit frames to the non-AP STA outside of the U-APSD coexistence service period, which begins when the AP receives a U-APSD trigger frame and ends after the transmission period specified by the result of the following calculation:

End of transmission period = *T* + *Duration*

where
T is the time the U-APSD trigger frame was received at the AP
Duration is the UAPSD Coexistence element Duration/Interval field value (see 9.4.2.89)

or upon the successful transmission of a frame with the EOSP subfield set to 1, whichever is earlier.

Throughout the U-APSD coexistence service period, the AP shall set the More bit to 1 if it has more frames to be transmitted and it can determine the frame might be received before the service period expires.

The AP should set the EOSP subfield to 1 in the frame that it expects to be the last frame transmitted to the non-AP STA during the U-APSD coexistence duration. If the last frame expected to be transmitted cannot be successfully transmitted to the non-AP STA before the termination of the U-APSD SP, or does not have QoS Control field, the AP should transmit a QoS Null frame with the EOSP subfield set to 1.

The non-AP STA may enter doze state at the end of the U-APSD coexistence service period.

11.2.3.6 AP operation

An AP shall maintain for each currently associated STA a Power Management status that indicates in which power management mode the STA is currently operating. APs that implement and signal their support of APSD shall maintain for each currently associated STA an APSD and an access policy status that indicates whether the STA is presently using APSD and shall maintain the schedule (if any) for the STA. An AP shall, depending on the power management mode of the STA, temporarily buffer BUs destined to the STA. An AP implementing APSD shall, if a STA is using APSD and is in PS mode, temporarily buffer BUs destined to that STA. No BUs addressed directly to STAs operating in the active mode shall be buffered for power management reasons. An HE AP should not transmit to an HE STA if the STA might be unavailable, as defined in 26.8.4.4 and 26.14.3, unless the transmission is solicited by the STA.

The following rules describe the operation:

a) BUs destined for PS STAs shall be temporarily buffered in the AP. The algorithm to manage this buffering is beyond the scope of this standard, with the exception that if the AP is QoS-enabled, it shall preserve the order of arrival of individually addressed frames sent to a given STA on a given TID.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

b) Nonbufferable MMPDUs and BUs destined for STAs in the active mode shall be directly transmitted to those STAs.

c) At every beacon interval, the AP shall assemble the partial virtual bitmap containing the buffer status per destination for STAs in the PS mode and shall send this out in the TIM element of the Beacon frame. At every beacon interval, the APSD-capable AP shall assemble the partial virtual bitmap containing the buffer status of nondelivery-enabled ACs (if there exists at least one nondelivery-enabled AC) per destination for STAs in PS mode and shall send this out in the TIM element of the Beacon frame. When all ACs are delivery-enabled, the APSD-capable AP shall assemble the partial virtual bitmap containing the buffer status for all ACs per destination. If FMS is enabled, the AP shall include the FMS Descriptor element in every Beacon frame. The FMS Descriptor element shall indicate all FMS group addressed frames that the AP buffers. An S1G AP should set the Duration field in the S1G Beacon frame to the estimated time required for all the S1G STAs that are indicated in the TIM elements and/or are allowed to access the first RAW immediately following the S1G Beacon frame as described in 10.23.5.4, to send the trigger or (NDP) PS-Poll frame and receive an acknowledgment from the AP. The operation described in this paragraph shall also be performed for every short beacon interval where a TIM is transmitted.

d) If a STA has set up a scheduled SP, the APSD-capable AP shall transmit frames associated with admitted traffic with the APSD subfield equal to 1 in the TSPECs buffered for the STA during a scheduled SP. If the STA has set up to use unscheduled SPs, the AP shall buffer BUs using delivery-enabled ACs until it has received a trigger frame using a trigger-enabled AC from the non-AP STA, which indicates the start of an unscheduled SP. A trigger frame received by the AP from a STA that already has an unscheduled SP underway shall not trigger the start of a new unscheduled SP. The AP transmits BUs destined for the STA and using delivery-enabled ACs during an unscheduled SP.

NOTE 1—Transmission of BUs during an unscheduled SP is constrained by the max SP length.

NOTE 2—The AC for delivery of an MMPDU (see 10.2.3.2) determines whether it is transmitted using a delivery-enabled AC during an unscheduled SP.

e) For an AP with dot11MultiBSSIDImplemented not true, the Traffic Indicator field in the Bitmap Control field of the TIM element shall be set to 1 when non-GCR-SP non-SYNRA group addressed traffic that is not to be delivered using group AID is buffered. For an AP with dot11MultiBSSIDImplemented set to true, the indication of group addressed traffic is described in 11.1.3.8.5.

f) If any associated non-GLK STAs are in PS mode, the AP shall buffer all non-GCR-SP group addressed BUs that arrive via the DS. If any GLK STA in its BSS is in PS mode, the AP shall not include any such STAs as a SYNRA destination and shall buffer all group addressed BUs destined to such STAs, delivering them with individually addressed MPDUs using power save delivery methods.

g) When dot11FMSActivated is false, the AP shall transmit all buffered non-GCR-SP non-SYNRA group addressed BUs immediately after every DTIM beacon or during broadcast TWT SPs within that beacon interval as defined in 26.8.3.2.

When dot11FMSActivated is true and the AP has established an FMS delivery interval for a multicast stream, the AP shall transmit all non-GCR-SP non-SYNRA group addressed BUs belonging to particular FMS stream immediately after the DTIM beacon that has the Current Count field of the FMS Counter field set to 0 for that particular FMS stream or during broadcast TWT SPs within that beacon interval as defined in 26.8.3.2.

The More Data subfield of each group addressed frame shall be set to indicate the presence of further buffered non-GCR-SP group addressed BUs to be delivered using MPDUs with an RA other than a SYNRA. If the AP is unable, before the primary or secondary TBTT following the DTIM beacon, to transmit all of the buffered non-GCR-SP group addressed BUs to be delivered using MPDUs with an RA other than a SYNRA, then the AP shall set the Traffic Indicator field in the TIM element to 1 for a single BSSID or set the corresponding group address bit to 1 for multiple BSSIDs, as defined in 9.4.2.5, and when dot11FMSActivated is true, shall set the appropriate bits in the FMS

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Descriptor element as described in 9.4.2.73 to indicate for which non-GCR-SP non-SYNRA group addresses there are still buffered BUs, until all buffered non-GCR-SP group addressed BUs to be delivered using MPDUs with an RA other than a SYNRA have been transmitted.

When the AP transmits an STBC Beacon frame, the AP shall retransmit all non-GCR-SP group addressed BUs to be delivered using MPDUs with an RA other than a SYNRA and that were transmitted following the non-STBC Beacon frame except that they are transmitted using the basic STBC MCS. It may be the case that a complete set of buffered non-GCR-SP non-SYNRA group addressed BUs is sent over a period of time during which non-STBC and STBC transmissions are interleaved, but the transition from non-STBC group addressed transmissions to STBC group addressed transmissions shall be preceded by the transmission of an STBC Beacon frame and the transition from STBC group addressed transmissions to non-STBC group addressed transmissions shall be preceded by the transmission of a non-STBC Beacon frame.

h) When the AP receives a PS-Poll frame from a STA that is in PS mode, it shall forward to the STA a buffered BU. The AP shall respond after a SIFS either with a Data or Management frame, or with an Ack frame; in which case the corresponding Data or Management frame is delayed. Until the transmission of this BU either has succeeded or is presumed failed (when maximum retries are exceeded), the AP shall acknowledge then discard all PS-Poll frames from the same STA. This prevents a retried PS-Poll frame from being treated as a new request to deliver a buffered BU.

NOTE 3—The BU might be delivered in multiple Data or Management frames.

For a STA using U-APSD, the AP transmits one BU destined for the STA from any AC that is not delivery-enabled in response to a PS-Poll frame from the STA. The AP should transmit the BU from the highest priority AC that is not delivery-enabled and that has a buffered BU. When all ACs associated with the STA are delivery-enabled, the AP transmits one BU from the highest priority AC that has a BU. Upon receiving a PS-Poll frame, the S1G AP may use the RTS/CTS scheme to protect the transmission of an immediate Data frame.

An S1G AP that sends an acknowledgment frame of type (NDP) Ack or NDP PS-Poll-Ack in response to an (NDP)PS-Poll/trigger frame that is received from an S1G STA shall set the More Data subfield of the acknowledgment frame to 0 when no BU is buffered for the STA; otherwise, it shall set it to 1. The reception of the acknowledgment frame provides the following indications to the S1G STA:

1) If the More Data subfield is equal to 0, it indicates that no service period starts for the STA and that it may enter the doze state,
2) If the More Data subfield is equal to 1, it indicates that a service period starts for the STA after a time T, starting from the end of the acknowledgment frame, after which the S1G STA shall remain in the awake state until a frame is received from the S1G AP that has the EOSP subfield equal to 1. The time T is equal to one of the following:
    i) 0 if the acknowledgment frame is an Ack frame or is an NDP (PS-Poll-)Ack frame with the Idle Indication subfield equal to 0.
    ii) The value indicated in the Duration field of the frame if the frame is an NDP (PS-Poll-)Ack frame with the Idle Indication subfield equal to 1.

For a STA in PS mode and not using U-APSD, the AP shall set the More Data subfield of the response Data or Management frame to 1 to indicate the presence of further buffered BUs (not including the BU currently being transmitted) for the polling STA.

For a STA using U-APSD, the AP shall set the More Data subfield to 1 to indicate the presence of further buffered BUs (not including the BU currently being transmitted) that do not use delivery-enabled ACs. When all ACs associated with the STA are delivery-enabled, the AP shall set the More Data subfield to 1 to indicate the presence of further buffered BUs (not including the BU currently being transmitted) using delivery-enabled ACs.

If there are buffered BUs to transmit to the STA, the AP may set the More Data bit in a QoS +CF-Ack frame to 1 in response to a QoS Data frame to indicate that it has one or more pending BUs

buffered for the PS STA identified by the RA in the QoS +CF-Ack frame. An AP may also set the More Data bit in an Ack frame to 1 in response to a QoS Data frame to indicate that it has one or more pending BUs buffered for the PS STA identified by the RA in the Ack frame, if that PS STA has set the More Data Ack subfield in the QoS Info field to 1. An HE AP may also set the More Data bit in a BlockAck or Multi-STA BlockAck frame to 1 to indicate that it has one or more pending BUs buffered for the HE PS STA identified by the RA in the BlockAck or Multi-STA BlockAck frame, if that HE PS STA has set the More Data Ack subfield in the QoS Info field to 1. An HE AP indicates support for sending Ack, BlockAck, or Multi-STA BlockAck frames with a nonzero More Data subfield by setting the More Data Ack subfield to 1 in the QoS Info field of frames it transmits.

Unless indicated above, the AP shall set the More Data bit to 0.

i) At each scheduled APSD SP for a STA, the APSD-capable AP (i.e., an AP for which dot11APSDOptionImplemented is true) shall attempt to transmit at least one BU, using admitted TSPECs with the APSD and Schedule subfields both set to 1, that are destined for the STA. At each unscheduled SP for a STA, the AP shall attempt to transmit at least one BU, but no more than the value specified in the Max SP Length field in the QoS Capability element from delivery-enabled ACs, that are destined for the STA.

NOTE 4—The transmission of one or more fragments of a BU counts as the transmission of one BU for the purposes of the constraint indicated by the Max SP Length field.

The AP shall set to 1 the More Data bit of an individually addressed MPDU containing all or part of a BU, using a delivery-enabled AC and destined for that STA, to indicate that more BUs (not including the BU currently being transmitted) are buffered for the delivery-enabled ACs. The AP shall set to 1 the More Data bit of an individually addressed MPDU containing all or part of a BU, using a nondelivery-enabled AC and destined for that STA, to indicate that more BUs (not including the BU currently being transmitted) are buffered for the nondelivery-enabled ACs.

In all frames except for the final frame of the SP, the AP shall set the EOSP subfield, if present, to 0 to indicate the continuation of the SP. An AP may also set the More Data bit to 1 in a QoS +CF-Ack frame in response to a QoS Data frame to indicate that it has one or more pending BUs buffered for the target STA identified by the RA in the QoS +CF-Ack frame. If the QoS Data frame is using a delivery-enabled AC, the AP shall set the More Data bit in the QoS +CF-Ack frame to 1 to indicate more BUs (not including the BU currently being transmitted) are buffered for the delivery-enabled ACs. If the QoS Data frame is not using a delivery-enabled AC, the AP shall set the More Data bit in the QoS +CF-Ack frame to 1 to indicate more BUs (not including the BU currently being transmitted) are buffered for the ACs that are not delivery-enabled.

Unless indicated above, the AP shall set the More Data bit to 0.

The AP considers an APSD STA to be in awake state after it has sent a QoS +CF-Ack frame, with the EOSP subfield equal to 0, to the APSD STA. If necessary, the AP may generate an extra QoS Null frame, with the EOSP subfield set to 1. When the AP has transmitted an individually addressed frame to the STA with the EOSP subfield set to 1 during the SP except for retransmissions of that frame, the AP shall not transmit any more frames to that STA using this mechanism until the next SP.

The AP shall set the EOSP subfield to 1 to indicate the end of the SP in APSD.

NOTE 5—Management frames do not have an EOSP subfield and so the end of the SP cannot be indicated in a Management frame. If the SP is to end after a Management frame, a QoS Null frame is used to indicate this.

The AP should not set the EOSP field to 1 in a frame that is not an individually addressed Data frame that requires immediate acknowledgment.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

j) If the AP does not receive an acknowledgment to an individually addressed MPDU containing all or part of a BU sent to a STA in PS mode following receipt of a PS-Poll frame from that STA, it may retransmit the frame for at most the lesser of the maximum retry limit and dot11QAPMissingAckRetryLimit times before the next Beacon frame, but it shall retransmit that frame at least once before the next Beacon frame, time permitting and subject to its appropriate lifetime limit. If an acknowledgment to the retransmission is not received, it may wait until after the next Beacon frame to further retransmit that frame subject to its appropriate lifetime limit.

k) If the AP does not receive an acknowledgment in response to a non-A-MPDU frame that is an individually addressed Data frame that is sent with the EOSP subfield equal to 1, and that requires immediate acknowledgment, it shall retransmit that frame at least once within the same SP, subject to applicable retry or lifetime limits. If the AP does not receive a BlockAck frame in response to an A-MPDU that contains one or more individually addressed Data frames that are sent with the EOSP subfield equal to 1, and that require immediate acknowledgment, it shall retransmit at least one of those frames at least once within the same SP, subject to applicable retry or lifetime limits. The maximum number of retransmissions within the same SP is the lesser of the maximum retry limit and dot11QAPMissingAckRetryLimit.

   If the AP does not receive an acknowledgment to an individually addressed Data or Management frame that requires immediate acknowledgment and that is not the initial attempt in this SP to send a frame with the EOSP subfield equal to 1, it may retransmit that frame in the next SP, subject to applicable retry or lifetime limits.

   An AP that transmits an A-MPDU containing Data frames in which the EOSP subfield is equal to 1 and that receives a BlockAck frame that does not acknowledge all of those MPDUs should not transmit any missed Data frames within the current service period because the destination STA might now be asleep.

k) An AP may delete buffered BUs for implementation dependent reasons (subject to 11.2.3.10), including the use of an aging function and availability of buffers. The AP may base the aging function on the listen interval indicated by the STA in its (Re)Association Request frame or the WNM sleep interval specified by the non-AP STA in the WNM Sleep Mode Request frame. In addition, the S1G AP may base the aging function on the listen interval indicated by the AP in the (Re)Association Response frame.

   NOTE 6—If for example the listen interval is 2, the AP might ensure it does not delete a buffered BU for age reasons until it has twice transmitted a beacon signaling the availability of the buffered BU, and has after this further allowed enough time (which is function of the channel occupancy and link quality) for the STA to request and obtain this buffered BU.

l) When an AP is informed that a STA has changed to the active mode, then the AP shall send buffered BUs (if any exist) to that STA without waiting for a PS-Poll frame. When an AP is informed that an APSD-capable STA is not using APSD, then the AP shall send buffered BUs (if any exist) to that STA according to the rules corresponding to the current PS mode of the STA.

11.2.3.7 Receive operation for STAs in PS mode

A STA in PS mode shall operate as follows to receive a BU from the AP:

a) A STA with dot11NonTIMModeActivated equal to false shall transition to awake state early enough to be able to receive the first Beacon frame scheduled for transmission at the time corresponding to the last TBTT or TSBTT for which the STA was awake plus the time interval indicated by the ListenInterval parameter of the MLME-ASSOCIATE.request or MLME REASSOCIATE.request primitive. A STA with dot11NonTIMModeActivated equal to true is not required to transition to awake state to receive a Beacon frame and shall transmit at least one PS-Poll or trigger frame that is individually addressed to the associated AP every listen interval starting from the last known transition of the S1G STA in non-TIM mode in doze state unless it follows the TWT or NDP Paging procedure.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—The STA might wake for a TBTT or TSBTT that is earlier than this deadline. In that case the previous requirement is reset based on a new "last TBTT or TSBTT".

b) When the STA detects that the bit corresponding to its AID is 1 in the TIM, the STA shall issue a PS-Poll frame, or a trigger frame if the STA is using U-APSD and all ACs are delivery-enabled, to retrieve the buffered BU. The PS-Poll or trigger frame shall be transmitted after a random delay uniformly distributed between zero and aCWmin slots following a DIFS.

NOTE 2—The BU might be delivered in multiple Data or Management frames.

c) The STA shall remain in the awake state until it receives the BU in response to its poll or it receives another Beacon frame whose TIM indicates that the AP does not have any BUs buffered for this STA. If the bit corresponding to the STA's AID is 1 in the subsequent TIM, the STA shall issue another PS-Poll frame to retrieve the buffered BU. When a STA that is using U-APSD and has all ACs delivery-enabled detects that the bit corresponding to its AID is 1 in the TIM, the STA shall issue a trigger frame or a PS-Poll frame to retrieve the buffered BU.

d) If the More Data subfield in the MPDU(s) containing the BU indicates that more traffic for that STA is buffered, the STA, at its convenience, shall poll until no more BUs are buffered for that STA.

e) When dot11FMSActivated is false and ReceiveDTIMBeacons is true, the STA shall transition to awake state early enough to be able to receive either every non-STBC DTIM beacon or every STBC DTIM beacon sent by the AP of the BSS. The STA shall remain in the awake state to receive the group addressed MPDUs transmitted by the AP as described in 11.2.3.1 and 11.2.3.4 when:

— the STA is associated with either an AP that has not set to 1 the Multiple BSSID field of the Extended Capabilities element it transmits or corresponds to the transmitted BSSID in a multiple BSSID set, and the Traffic Indicator field in the TIM element in the DTIM beacon is equal to 1, or

— the STA is associated with an AP that corresponds to a nontransmitted BSSID in a multiple BSSID set, and the field corresponding to the BSSID index (i.e., a bit position between 1 and 2^n – 1 of the Partial Virtual Bitmap field matching the BSSID index of a nontransmitted BSSID) in the TIM element is equal to 1 in the DTIM beacon of that nontransmitted BSSID.

When dot11FMSActivated is true and ReceiveDTIMBeacons is true and the STA has been granted by the AP an alternate delivery interval for a multicast stream, the STA shall transition to awake state before the DTIM beacon having the Current Count field of the FMS Counter field set to 0 for that particular FMS stream.

A STA that stays awake to receive group addressed BUs shall elect to receive all group addressed non-STBC transmissions or all group addressed STBC transmissions and remain awake until the More Data subfield of the appropriate type (non-STBC or STBC) of group addressed BUs indicates there are no further buffered group addressed BUs of that type, or until a TIM is received indicating there are no more buffered group addressed BUs of that type, or until an FMS Descriptor element is received indicating that there are no further buffered group addressed BUs for which the STA has previously received an FMS Response element in a frame that has a value in Address 1 that matches its MAC address or that has an Address 1 value that is a group address corresponding to a group of which it is a member and that was transmitted by the AP with which it is associated and which had an Element Status value in the FMS Status subelement of "Accept". If a STA receives a QoS +CF-Ack frame from its AP with the More Data bit equal to 1, then the STA shall operate as if it received a TIM with its AID bit equal to 1. If a STA has set the More Data Ack subfield in the QoS Info field to 1, then if it receives an Ack frame from its AP with the More Data bit equal to 1, the STA shall operate as if it received a TIM with its AID bit equal to 1. If an HE STA has set the More Data Ack subfield in the QoS Info field to 1, then if it receives a BlockAck or Multi-STA BlockAck frame from its AP with the More Data bit equal to 1, the STA shall operate as if it received a TIM with its AID bit equal to 1. For example, a STA that is using the PS-Poll delivery method shall issue a PS-Poll frame to retrieve a buffered BU. See also 10.3.6.

11.2.3.8 Receive operation using APSD

A STA using APSD shall operate as follows to receive a BU from the AP:

a) If a scheduled SP has been set up, the STA transitions from doze to awake state at its scheduled start time. (The STA shall transition to awake state early enough to receive transmissions at the scheduled SP.)

b) If the STA is initiating an unscheduled SP, the STA wakes up and transmits a trigger frame to the AP. When one or more ACs are not delivery-enabled, the STA may retrieve BUs using those ACs by sending PS-Poll frames to the AP.

c) The STA shall remain awake until it receives a QoS Data frame or QoS Null frame addressed to it, with the EOSP subfield equal to 1.

d) The STA may send additional PS-Poll frames if the More Data subfield is 1 in a downlink individually addressed MPDU containing all or part of a BU that does not use a delivery-enabled AC. The STA may send additional trigger frames if the More Data subfield is 1 in a downlink individually addressed MPDU containing all or part of a BU that uses a delivery-enabled AC.

For receive operation using the U-APSD coexistence mechanism, see additional procedures in 11.2.3.5.2.

11.2.3.9 STAs operating in the active mode

A STA operating in this mode shall have its receiver activated continuously, unless the STA is allowed to be temporarily unavailable through the opportunistic power save mechanism defined in 26.14.3 or through the intra-PPDU power save mechanism defined in 26.14.1 or 26.8.4.4; such STAs do not need to interpret the TIM elements in Beacon frames.

11.2.3.10 AP aging function

Any AP aging function shall not cause the buffered BU to be discarded after any period that is shorter than that indicated by the STA for which the BUs are buffered, in the Listen Interval field of its (Re)Association Request frame. The exact specification of the aging function is beyond the scope of this standard.

NOTE—This aging function is independent of (i.e., in addition to) other causes of MSDU discard within the MAC, such as due to the operation of a per-TS MSDU lifetime, or related to dot11QAPEDCATableMSDULifetime.

11.2.3.11 TDLS peer power save mode

TDLS peer power save mode (TDLS peer PSM) is a power save mechanism that can be used between TDLS peer STAs, and which is based on a periodic wakeup schedule. A station that signals support for this capability is capable of acting in both the TDLS peer PSM initiator and the TDLS peer PSM responder role.

In order to enter TDLS peer PSM (TDLS peer PSM initiator), a STA shall send a TDLS Peer PSM Request frame to the TDLS peer STA (TDLS peer PSM responder), including a proposed periodic wakeup schedule. A TDLS Peer PSM Request frame shall not be transmitted to a STA that did not indicate support for TDLS peer PSM. When the TDLS peer PSM responder accepts the proposed wakeup schedule, it shall respond with a TDLS Peer PSM Response frame indicating status code SUCCESS. Otherwise, the TDLS peer PSM responder shall respond with a TDLS Peer PSM Response frame indicating the appropriate status code for rejecting the schedule. An alternative schedule shall be included in the TDLS Peer PSM Response frame when the status code is equal to TDLS_REJECTED_ALTERNATIVE_PROVIDED. The alternative schedule may be used by the TDLS peer PSM initiator to generate a new TDLS Peer PSM Request frame. After successfully transmitting or receiving a TDLS Peer PSM Response frame indicating status code SUCCESS, the TDLS peer PSM initiator and TDLS peer PSM responder have established a periodic wakeup schedule between them. The wakeup schedule remains valid until one of the following occurs:

— The TDLS direct link is torn down;

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The STAs explicitly update the existing wakeup schedule; or
— No MPDUs containing data have been exchanged for Idle Count consecutive Awake Windows.

A STA transmitting a TDLS Peer PSM Request frame shall remain in the awake state until it received the corresponding TDLS Peer PSM Response frame. A TDLS Peer PSM Request frame may be transmitted via the AP path or via the direct path (which is up to the implementer to decide). A TDLS Peer PSM Response frame shall be transmitted over the direct path.

The timing of the periodic schedule of the TDLS Peer PSM awake windowsis based on the Offset field, the Interval field, the Awake Window Slots field, and the Maximum Awake Window Duration field of the Wakeup Schedule element that is contained in the TDLS Peer PSM Request frame that established TDLS peer PSM operation on the link.

Awake windows begin at TSF values that satisfy Equation (11-1) and that are after the TDLS Peer PSM Request/Response frame exchange has completed, where Interval and Offset are the fields of the Wakeup Schedule element.

$$\text{TSF mod Interval} = \text{Offset} \tag{11-1}$$

NOTE —The awake window timings might not be related to the beacon timings (TBTTs).

Awake windows end when the awake window slot counter reaches 0 or when the maximum awake window duration has been reached, whichever comes first.

The awake window slot counter counts down backoff slots that are determined using AIFS[AC_BE] in the same manner that normal backoff slots are determined according to 10.23.2.4.

The initial value of the awake window slot counter at the start of the awake window shall be equal to the value in the Awake Window Slots field of the Wakeup Schedule element that is contained in the TDLS Peer PSM Request frame that established TDLS peer PSM operation on the link.

The awake window slot counter begins counting at the beginning of the awake window and stops counting when it reaches 0.

A value of 0 in the Maximum Awake Window Duration field of the Wakeup Schedule element that is contained in the TDLS Peer PSM Request frame that established TDLS peer PSM operation on the link means that the end of the awake window duration is determined only by the awake window slot counter.

A value of 0 in the Awake Window Slots field of the Wakeup Schedule element that is contained in the TDLS Peer PSM Request frame that established TDLS peer PSM operation on the link means that the duration of the awake window is determined only by the maximum awake window duration.

The Maximum Awake Window Duration field and the Awake Window Slots field shall not both be set to 0 in a TDLS Peer PSM Request frame.

The Awake Window Slots field in a TDLS Peer PSM Request frame should be set to a value that is larger than CWmin[AC_BE].

A TDLS peer PSM service period is a period of time during which one or more individually addressed frames are transmitted between two TDLS peer STAs when at least one STA employs TDLS peer PSM. A TDLS peer PSM service period may be initiated during an awake window. A TDLS peer STA in power save mode may enter a doze state when it has successfully transmitted to and received from the corresponding TDLS peer STA in power save mode a QoS frame with the EOSP subfield equal to 1, ending the TDLS peer PSM service

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

period. A TDLS peer STA in power save mode may enter a doze state when it has received from the corresponding TDLS peer STA in active mode a QoS frame with the EOSP subfield equal to 1.

Either STA may update an existing schedule by initiating a TDLS peer PSM Request/Response frame exchange. If the TDLS Peer PSM Response frame indicates status code SUCCESS, a new wakeup schedule is established for the TDLS direct link. Otherwise, the existing schedule still applies. The new schedule takes effect after the termination of the current TDLS peer PSM service period.

After the successful PSM setup, a STA informs its TDLS peer STA that it will enter power save mode per TDLS direct link by setting the Power Management subfield to 1 in an MPDU requiring immediate acknowledgment. The STA enters power save mode after successful transmission of the MPDU. The power save status on one TDLS direct link is independent of the power save status on other links (direct or with the AP) the STA may have.

If a TDLS peer STA enters power save mode when a wakeup schedule is active, it shall be awake at the beginning of each scheduled periodic awake window, and stay awake for the duration of the awake window or until the end of a TDLS peer PSM service period. Otherwise, it may enter a doze state, depending on the current requirements to be awake, imposed by other links. A TDLS peer STA that did not enter power save mode shall remain in the awake state.

When both TDLS peer STAs set the More Data Ack subfield in their QoS Capability element to 1, then the More Data subfield inside an Ack frame set to 0 shall have the same function as the EOSP subfield inside a QoS frame set to 1. Transmission of an Ack frame with the More Data subfield set to 0 under these conditions is equivalent to a successful transmission of a QoS frame with the EOSP subfield set to 1.

When waking up at the beginning of an awake window, if a STA has no buffered BU to send to a TDLS Peer STA that had the More Data Ack subfield in its QoS Capability element equal to 1 during the TDLS setup exchange, the TDLS STA may send a QoS Null frame with the EOSP subfield of the QoS Control field set to 1, and the More Data subfield of the Frame Control field set to 0. If the TDLS peer STA that is the recipient of this QoS Null frame also has no buffered BU to deliver either, and it had the More Data Ack subfield in its QoS Capability element equal to 1 during the TDLS setup exchange, then the TDLS peer STA shall respond with an Ack frame that has the More Data subfield set to 0. The STA may discard the QoS Null frame if it has not been successfully transmitted at the end of the awake window. Before the successful transmission of the QoS Null frame, if a QoS Data or QoS Null frame, with an EOSP subfield equal to 1, is received from the TDLS peer STA the STA may cancel the pending transmission of the QoS Null frame after the transmission of an Ack frame with the More Data subfield set to 0.

To keep track of the connectivity over the TDLS direct link and to maintain the wakeup schedule, a TDLS peer STA may start an acknowledged frame exchange sequence at least once per Idle Count consecutive awake windows, as a keepalive. For instance a QoS Null frame may be used as a keepalive frame. When a TDLS Peer PSM Response frame was successfully transmitted or received and no subsequent TDLS peer PSM service period has started for Idle Count consecutive wakeup periods, a TDLS peer STA shall delete the wakeup schedule for this link, which means that the related periodic wakeup no longer occurs (i.e., the TDLS peer STA no longer has to transition to awake state during this period) and that a wakeup schedule no longer exists for this link. When traffic arrives at a TDLS peer STA in TDLS peer PSM mode for a link with no existing wakeup schedule, the STA shall send a TDLS Peer PSM Request frame through the AP path to the TDLS peer STA to activate a new wakeup schedule. When both TDLS peer STAs enter active mode while a wakeup schedule is active, no more TDLS peer PSM service periods will occur, causing the wakeup schedule to be deleted.

If a TDLS peer STA does not receive an acknowledgment to an individually addressed QoS frame sent with the EOSP subfield equal to 1 that terminates a TDLS peer PSM service period, it shall retransmit that frame at least once within the same service period, subject to the applicable retry or lifetime limit. The maximum number of retransmissions within the same service period is the lesser of the maximum retry limit and dot11TDLSPeerSTAMissingAckRetryLimit. If an acknowledgment to the retransmission of this last frame in

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the same service period is not received, the TDLS peer STA may wait until the next awake window to further retransmit that frame, subject to its applicable retry or lifetime limit. When the TDLS peer STA has transmitted an individually addressed frame that terminates a TDLS peer PSM service period then, except for retransmissions of that frame, the TDLS peer STA shall not transmit any more frames to the TDLS peer STA until the next awake window.

A TDLS peer STA that has an active wakeup schedule shall not decrement a backoff count outside the awake windows, if that backoff precedes a frame that is destined for transmission on the related TDLS direct link.

At the start of an awake window, the backoff procedure shall be invoked at an EDCAF if there is a frame available for transmission at that EDCAF, and the backoff counter for that EDCAF has been 0 for at least one backoff slot.

Outside of its awake windows, and during awake windows when on the base channel, a TDLS peer STA can engage in communications with the AP.

11.2.3.12 TDLS peer U-APSD (TPU)

11.2.3.12.1 General

A STA supports the TPU buffer STA function if dot11TDLSPeerUAPSDBufferSTAActivated is true. dot11TDLSPeerUAPSDBufferSTAActivated is false in a non-QoS STA. A STA supporting this function shall indicate this by setting the TPU Buffer STA Support subfield in the Extended Capabilities element included in the TDLS Setup Request frame or TDLS Setup Response frame to 1. Support for the TPU buffer STA function means that the STA has the capability to buffer BUs destined to the TPU sleep STA, and to deliver them during unscheduled service periods.

To operate as the TPU sleep STA in TPU, a STA shall configure its TPU capable TDLS peer STA by setting one or more U-APSD Flag subfields inside the QoS Info subfield of the QoS Capability element carried in a TDLS Setup Response frame to 1, or by setting one or more U-APSD Flag subfields inside the QoS Info subfield of the EDCA Parameter Set element carried in a TDLS Setup Confirm frame to 1.

A STA that configured TPU at a TDLS peer STA enters power save mode on a TDLS direct link after the successful transmission to the TDLS peer STA over the TDLS direct link of an acknowledged MPDU with the Power Management subfield equal to 1. The STA that transmitted the frame with the Power Management subfield equal to 1 is then referred to as a *TPU sleep STA*. The STA that received the frame with the Power Management subfield equal to 1 is referred to as a *TPU buffer STA*. A TPU sleep STA may be a TPU buffer STA at the same time and on the same link, by sending a frame to the TDLS peer STA with the Power Management subfield of the Frame Control field set to 1 (this transmission is preceded by the transmission of a Peer Traffic Indication frame and the subsequent receipt of a trigger frame that starts a service period). The power save status on one TDLS direct link is independent of the power save status on other links (direct or with the AP) the STA may have.

The procedure to trigger and terminate an unscheduled SP between TPU buffer STA and a TPU sleep STA are described in 11.2.3.5 and 11.2.3.6, where the TPU buffer STA shall take the role of the AP and the TPU sleep STA shall take the role of the non-AP STA using U-APSD, except that a frame with the EOSP subfield equal to 1 shall not act as a trigger frame.

11.2.3.12.2 TPU at the TPU buffer STA

BUs at a TPU buffer STA destined for a TPU sleep STA shall be temporarily buffered at the TPU buffer STA. The algorithm to manage this buffering is beyond the scope of this standard, except that the TPU buffer STA shall preserve the order of buffered BUs for a given STA on a given TID.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A TPU buffer STA shall transmit an individually addressed TDLS Peer Traffic Indication frame to a TPU sleep STA, through the AP, if all of the following conditions are met:

— A BU destined for a TPU sleep STA was placed into a buffer at the TPU buffer STA;
— The buffer into which the BU was placed contained no other frames with the same RA; and
— One or more periods of dot11TDLSPeerUAPSDIndicationWindow beacon intervals have expired after the last service period.

Otherwise it shall not transmit this frame.

The TDLS Peer Traffic Indication frame shall be transmitted through the AP path.

The transmitted TDLS Peer Traffic Indication frame shall indicate the nonempty AC(s), by setting the corresponding AC Traffic Available subfield of the TDLS Peer Traffic Indication frame to 1.

A PTI Control element may be included in the TDLS Peer Traffic Indication frame, to allow the TPU sleep STA to not start a service period when the indicated traffic has already been received by the TPU sleep STA.

The TID field contained in the PTI Control element (if included) shall be set to the TID of the latest MPDU that has been transmitted over the TDLS direct link to the TPU sleep STA that is the destination of the TDLS Peer Traffic Indication frame that contains the PTI Control element.

The Sequence Control field contained in the PTI Control element (if included) shall be set to the sequence number of the latest MPDU that has been transmitted over the TDLS direct link to the TPU sleep STA that is the destination of the TDLS Peer Traffic Indication frame that contains the PTI Control element.

After transmitting a TDLS Peer Traffic Indication frame without a PTI Control element, the TPU buffer STA shall stay awake at least until the corresponding or a subsequent TDLS Peer Traffic Response frame is received.

After transmitting a TDLS Peer Traffic Indication frame without a PTI Control element, the TPU buffer STA shall stay awake at least until the MPDU following the MPDU indicated in the Sequence Control field of the PTI Control element is successfully transmitted.

When no corresponding TDLS Peer Traffic Response frame has been received within dot11TDLSResponseTimeout after sending a TDLS Peer Traffic Indication frame, the STA shall tear down the TDLS direct link.

11.2.3.12.3 TPU at the TPU sleep STA

When a TPU sleep STA receives a TDLS Peer Traffic Indication frame without a PTI Control element, the TPU sleep STA shall initiate a service period with the TPU buffer STA during which it shall transmit at least a TDLS Peer Traffic Response frame. The TDLS Peer Traffic Response frame shall echo the values of the Dialog Token and Link Identifier fields from the corresponding TDLS Peer Traffic Indication frame. The TDLS Peer Traffic Response frame shall be sent via the direct path.

When a TPU sleep STA receives a TDLS Peer Traffic Indication frame with a PTI Control element, and the TPU sleep STA has not received from the TPU buffer STA the MPDU following the MPDU that is indicated in the TDLS Peer Traffic Indication frame, the TPU sleep STA shall initiate a service period with the TPU buffer STA to retrieve the buffered traffic for the AC(s) for which no unscheduled SP is currently active.

11.2.3.13 FMS power management

11.2.3.13.1 General

Implementation of FMS is optional for a WNM STA. A STA with dot11FMSActivated equal to true shall support FMS and shall set to 1 the FMS field of the Extended Capabilities elements that it transmits.

11.2.3.13.2 FMS general procedures

When dot11FMSActivated is true at the AP, the AP shall include the FMS Descriptor element in every Beacon frame. The FMS Descriptor indicates the FMS group addressed buffered BUs at the AP. If there are no buffered BUs for FMS streams accepted by the AP, the AP shall set the Length field in the FMS Descriptor element to 1. The AP shall include the FMS Descriptor element for a nontransmitted BSSID in the corresponding Nontransmitted BSSID Profile subelement carried in the Multiple BSSID element sent in a Beacon frame.

When dot11FMSActivated is true at the AP, the AP shall support from one to eight different FMS stream delivery intervals for any number of FMS streams. Corresponding to these eight delivery intervals are eight FMS counters. More than one FMSID may have the same delivery interval and therefore share the same FMS counter. An FMS counter corresponds to each unique delivery interval of one or more FMS streams.

Each FMS counter decrements once per DTIM beacon and when the FMS counter reaches 0, buffered group addressed BUs assigned to that particular interval are scheduled for delivery immediately following the next DTIM beacon. After transmission of the buffered group addressed BUs, the AP shall reset the FMS counter to the delivery interval for the FMS streams associated with that FMS counter.

A non-AP STA that does not use FMS wakes every DTIM interval and follows group addressed BU reception rules as defined in 11.2.3.7.

A STA that supports FMS shall support a delivery interval of 1 DTIM interval for any stream.

11.2.3.13.3 FMS Request procedures

A non-AP STA that supports FMS may request use of FMS by sending an FMS Request frame or Reassociation Request frame that includes one or more FMS Request elements to an AP that supports FMS. Each FMS Request element includes one or more FMS subelements. Each FMS subelement identifies an FMS stream, the requested delivery interval and the maximum delivery interval for that stream. The FMS delivery interval shall be an integer multiple of the DTIM period.

Upon reception of an FMS Request frame or Reassociation Request frame, the AP shall transmit a corresponding single FMS Response frame or Reassociation Response frame that contains a corresponding FMS Response element for each FMS Request element in the same order received. Each FMS Response element shall contain an FMS Status subelement and zero or more other subelements drawn from Table 9-259 that corresponds to each FMS subelement in the FMS Request element, in the same order.

For each FMS subelement, the following rules apply:

If the AP accepts the FMS subelement and the requested delivery interval, the Element Status in the corresponding FMS Status subelement shall be set to “Accept” and the FMSID is assigned to a nonzero value. In addition:

— If the FMS stream identified in the FMS subelement matches a delivery interval already in use at the AP, the AP shall assign the FMS stream to use the FMS counter ID assigned for that delivery interval.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

- When an FMS stream is accepted by the AP, the Current Count value for that FMS stream is decremented by 1 for each DTIM beacon in which the Current Count field appears.
- The AP may reschedule transmission of the FMS stream identified by an FMSID to align the transmission time of the FMS stream to the transmission time of other FMS streams that the STA is already receiving at the same delivery interval. The AP has the following two options:
  - Notify the STAs using that FMS stream. The AP shall keep the nonzero Current Count value the same across two consecutive Beacon frames in which the Current Count field appears. The algorithm by which the AP chooses to align or offset the different FMS counters is unspecified.
  - Transmit an unsolicited FMS Response frame to the group address included in the original FMS Response frame for the stream with the updated Delivery Interval field when the Current Count field value reaches 0. Since the AP transmits this FMS Response frame as a group addressed frame, the frame will be scheduled for delivery at the appropriate DTIM interval when all non-AP STAs are awake to receive the frame.
- An AP may terminate the use of FMS and resume default (non-FMS) transmission rules for any FMS stream identified by FMSID for any reason. To terminate the FMS stream, the AP shall send an unsolicited FMS Response frame to the group address included in the original FMS Response frame with Delivery Interval set to 0 and the Element Status in the FMS Status subelement set to one of "Terminate, due to AP policy change", "Terminate, due to lack of resources of AP," and "Terminate, due to other FMS stream with higher priority".
- If the FMS subelement contained a nonzero delivery interval and the non-AP STA specified a maximum delivery interval as part of the FMS request, the AP shall not modify the delivery interval for the stream greater than the maximum delivery interval specified by the non-AP STA.
- An AP shall transmit MSDUs belonging to the same FMSID in the same order that they were received at the MAC Data SAP. MSDUs belonging to the different FMSIDs are transmitted by the AP at the appropriate DTIM beacon in the order received at the MAC data SAP based on the interval configured for the FMS stream.

If the AP denies the FMS subelement for any reason, including requested delivery interval, maximum delivery interval and TCLAS, the Element Status in the corresponding FMS Status subelement shall be set to one of "Deny, due to request format error or ambiguous classifier", "Deny, due to lack of resources on AP", "Deny, due to requested classifier(s) matching 2 or more existing streams on different intervals," "Deny, by policy, requested stream or filter is not permitted to participate in the service", and "Deny, reason unspecified".

If the AP selects an alternate delivery interval or alternate maximum delivery interval from the value specified in the FMS Request frame or Reassociation Request frame, the Element Status field in the corresponding FMS Status subelement shall be set to one of "Alternate proposed, due to existing stream with different delivery interval", "Alternate proposed, due to policy limits on AP", "Alternate proposed, because the AP changed the delivery interval", and "Alternate proposed, because the AP changed the maximum delivery interval" and the FMS subelement shall indicate the AP selected value(s).

To terminate the use of FMS for an FMS stream identified by FMSID, the non-AP STA shall transmit an FMS Request frame with an FMS Request element and FMS subelement with the FMSID matching the FMS stream and the delivery interval set to 0.

The AP shall respond to a malformed FMS Request frame or Reassociation Request frame with an FMS Response frame or Reassociation Response frame that denies all FMS Request elements by including an FMS status code"Deny, due to request format error or ambiguous classifier" in the Element Status field in each FMS Status subelement in the FMS Response element.

11.2.3.13.4 FMS Response procedures

Upon reception of an FMS Response element in a frame that has a value in Address 1 that matches its MAC address or that is a group address corresponding to a group of which it is a member and that was transmitted by the AP with which it is associated, a non-AP STA that supports FMS shall use the following procedures, based on the value of the Element Status value in the FMS Status subelement in the received FMS Response element.

- If the Element Status value in the FMS Status subelement is "Accept":
  - The AP has accepted the FMS subelement contained within the FMS Request element. If the FMS Request element specified a nonzero delivery interval, the AP will deliver the requested streams at the delivery interval as specified by the non-AP STA in the FMS Request element.
  - After receiving the FMS Response element, the non-AP STA shall be awake for the next DTIM beacon so that the non-AP STA can synchronize with the FMS Current Count for the requested FMS stream. Once synchronized with the FMS Current Count, the non-AP STA need not transition to awake state at every DTIM interval to receive group addressed BUs.
- If the Element Status value in the FMS Status subelement is one of "Deny, due to request format error or ambiguous classifier", "Deny, due to lack of resources on AP", "Deny, due to requested classifier(s) matching 2 or more existing streams on different intervals", "Deny, by policy, requested stream or filter is not permitted to participate in the service", and "Deny, reason unspecified":
  - The AP does not deliver the requested streams at the delivery interval as specified by the non-AP STA in the FMS Request element. The AP delivers the requested stream at every DTIM interval.
- If the Element Status value in the FMS Status subelement is one of "Alternate proposed, due to existing stream with different delivery interval", "Alternate proposed, due to policy limits on AP", "Alternate proposed, because the AP changed the delivery interval", and "Alternate proposed, because the AP changed the maximum delivery interval":
  - The AP does not deliver the requested streams at the delivery interval and maximum delivery interval as specified by the non-AP STA in the FMS Request element. The FMS Status subelement specifies a delivery interval and a maximum delivery interval that the AP is willing to accept for the specified streams if the non-AP STA sends another FMS Request frame or Reassociation Request frame with that delivery interval and maximum delivery interval specified.
  - The non-AP STA may submit a new FMS Request frame or Reassociation Request frame that includes the delivery interval value received from the AP. If the AP accepts this new FMS Request frame or Reassociation Request frame, it shall respond as described in 11.2.3.13.2.
- If the Element Status value in the FMS Status subelement is "Alternate proposed, because the AP is unable to provide requested TCLAS-based classifiers":
  - The AP does not deliver the requested streams at the delivery interval as specified by the non-AP STA in the FMS Request element. The TCLAS element(s) or TCLAS Processing element in the TCLAS Status subelement contains one or more fields or subfields whose values have been modified by the AP. The AP may include fewer TCLAS elements in the FMS Response element than were present in the request; when the AP's response includes a single TCLAS element, it does not include a TCLAS Processing element. If the AP changes a TCLAS element's Classifier Type field in the FMS Response element but is unable to suggest a value for the Classifier Mask field, it shall set that field to 0. If the AP changes a TCLAS element's Classifier Type field or Classifier Mask field in the FMS Response element but is unable to suggest values for one or more Classifier Parameter subfields, it shall set those fields to 0.
  - A non-AP STA receiving a modified TCLAS element having a Classifier Mask field equal to 0 or Classifier Parameter subfields equal to 0 shall interpret these values as meaning that no suggested value has been provided by the AP.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— If the Element Status value in the FMS Status subelement is one of “Terminate, due to AP policy change”, “Terminate, due to lack of resources of AP”, and “Terminate, due to other FMS stream with higher priority”:
  — The AP terminates the use of FMS transmission rules for any FMS stream identified by FMSID. If the AP terminates the usage of FMS for a particular stream, the stream is transmitted at DTIM interval.
  — The non-AP STA shall transition to awake state at every DTIM interval to receive group addressed BUs after receiving the FMS Response element.

11.2.3.14 TIM Broadcast

Implementation of TIM Broadcast is optional for a WNM STA. A STA that implements TIM Broadcast has dot11TIMBroadcastImplemented equal to true. When dot11TIMBroadcastImplemented is true, dot11WirelessManagementImplemented shall be true. A STA with dot11TIMBroadcastActivated equal to true shall support TIM Broadcast and shall set to 1 the TIM Broadcast field of the Extended Capabilities elements that it transmits. This subclause describes TIM broadcast procedures for STAs with dot11TIMBroadcastActivated equal to true.

TIM frames have shorter duration than Beacon frames and are potentially transmitted at a higher data rate. TIM Broadcast allows a non-AP STA to receive a TIM element without receiving a Beacon frame that may reduce the required wake time in a power save mode. The shorter receive time reduces the power consumption for non-AP STAs in a power save mode. The shorter receive time may reduce the power consumption for stations in a standby mode.

A non-AP STA may activate the TIM broadcast service by including a TIM Broadcast Request element in a TIM Broadcast Request frame, Association Request frame or Reassociation Request frame that is transmitted to the AP, which specifies the requested interval between TIM frame transmissions (the TIM broadcast interval). On receipt of a properly formatted TIM Broadcast Request element in a TIM Broadcast Request frame, Association Request frame or Reassociation Request frame, the AP shall include a TIM Broadcast Response element in the corresponding TIM Broadcast Response frame, Association Response frame or Reassociation Response frame, when dot11TIMBroadcastActivated is true. A non-AP STA shall transmit a TIM Broadcast Request only if the associated AP has indicated support for TIM Broadcast by setting the TIM Broadcast field of the Extended Capabilities elements that it transmits to 1.

NOTE 1—An OPS AP that transmits TIM frames as described in 26.14.3 is expected to encode the TIM bits such that an associated non-AP STA that does not support OPS operation can use the information received in the TIM frame as it would do when receiving a TIM frame transmitted following the TIM Broadcast procedure.

When the requested TIM broadcast interval is acceptable, the AP shall include a TIM Broadcast Response element specifying the requested TIM broadcast interval and a Status field indicating “Accept” when noTSF timestamp is present in the TIM frames, or “Accept, timestamp present in TIM frames” when a TSF timestamp is present in the TIM frames. When the AP overrides the requested TIM broadcast interval, it shall include a TIM Broadcast Response element specifying a different TIM broadcast interval and a Status field indicating “Overridden” when no TSF timestamp is present in the TIM frames, or “Overridden, timestamp present in TIM frames” when a TSF timestamp is present in the TIM frames, and include in the TIM Broadcast Response element the smallest TIM broadcast interval that is currently active. Otherwise, the AP shall include a TIM Broadcast Response element with a Status field indicating “Denied.” The Status field in a TIM Broadcast Response element that is included in an Association Response frame or Reassociation Response frame has implications only for the TIM Broadcast negotiation.

NOTE 1—The STA might ignore the TIM Broadcast Interval field in the TIM Broadcast Response element if the Status field indicates “Accept” or “Accept, timestamp present in TIM frames”, because the TIM broadcast interval is the requested one.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the AP accepted at least one TIM Broadcast Request with a nonzero TIM Broadcast Interval field, and at least one non-AP STA in PS mode still associated with the AP received in its latest TIM Broadcast Response a status field value equal to 0 (Accepted) in response to a TIM Broadcast Request with a nonzero TIM Broadcast Interval field, the AP shall transmit one or two TIM frames per TIM Broadcast Interval. The AP shall not transmit TIM frames otherwise. When TIM broadcast intervals overlap, a transmitted TIM frame serves both intervals and does not need to be duplicated.

If the AP transmits two TIM frames per TIM Broadcast Interval, the AP shall transmit the high data rate TIM frame first, followed by the low data rate TIM frame.

The AP shall transmit the low data rate TIM frame at the same data rate or MCS as the Beacon frame. The AP shall transmit the high data rate TIM frame at a higher data rate or using an MCS that corresponds to a higher data rate. For Clause 18 and Clause 19 PHYs, if the Beacon frame is transmitted using ERP-DSSS/CCK, the AP shall transmit the high data rate TIM frame and shall transmit it using ERP-OFDM. Otherwise, transmitting the high data rate TIM frame is optional. If the high data rate TIM is not transmitted, the AP shall set the High Rate TIM Rate field to 0 in the TIM Broadcast Response element.

The TIM Broadcast Interval field from the latest received TIM Broadcast Response element (N_TBI) together with dot11BeaconPeriod define a series of target TIM transmission times (TTTTs) N_TBI × dot11BeaconPeriod TUs apart. Time 0 is a TTTT. A non-AP STA may use the information in the High Rate TIM Rate and Low Rate TIM Rate fields to determine which of the two TIM frames they will be receiving. The first TIM frame per TIM broadcast interval is scheduled to be transmitted at the TTTT plus the indicated TIM broadcast offset. The offset may have a negative value that allows the TIM frame(s) to be transmitted before the TBTT. The value of the offset shall not be changed as long as an associated non-AP STA is using the TIM broadcast service.

The AP should accept new TIM broadcast interval requests if this implies transmitting TIM frames more frequently. For instance, if the AP currently transmits TIM frames every fourth beacon period and it receives a new request for every 3 beacon periods, then the AP should accept the new request and transmit TIM frames both every 3 and every 4 beacon periods. The AP may override incongruent requests once available resources (such as counters) have been depleted. An incongruent request is a request that contains an interval that is not an integer divide or a multiple of a currently active TIM Broadcast interval.

The AP shall accept a TIM broadcast interval of 1.

NOTE 2—The DTIM Period subfield in a TIM element in a TIM frame indicates the period for DTIM beacons and is unrelated to any TIM Broadcast Interval(s).

The AP shall increase the value (modulo 256) of the Check Beacon field in the next transmitted TIM frame(s) when a critical update occurs to any of the elements inside the Beacon or DMG Beacon frame. The following events shall classify as a critical update:

a) Inclusion of a Channel Switch Announcement element
b) Inclusion of an Extended Channel Switch Announcement element
c) Modification of the EDCA parameters element
d) Inclusion of a Quiet element
e) Modification of the DSSS Parameter Set
f) Modification of the HT Operation element
g) Inclusion of a Wide Bandwidth Channel Switch element
h) Inclusion of a Channel Switch Wrapper element
i) Inclusion of an Operating Mode Notification element

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

j) Inclusion of a Quiet Channel element
k) Modification of the VHT Operation element
l) Modification of the HE Operation element
m) Insertion of a Broadcast TWT element
n) Inclusion of the BSS Color Change Announcement element
o) Modification of the MU EDCA Parameter Set element
p) Modification of the Spatial Reuse Parameter Set element
q) Modification of the UORA Parameter Set element
r) Insertion of an Index Adjustment Factor field in a Multiple BSSID Configuration element

NOTE 4—Modification of an element means that at least one field in the element is changed, although not all fields in an element can be changed (e.g., the fields that advertise the basic MCS sets in HT Operation, VHT Operation, and HE Operation elements do not change). Inclusion of an element means that the element is included in a Beacon frame. The insertion of an element means that the element was not present in the previous Beacon frame, is present in the current Beacon frame, and will be carried in the next Beacon frame.

An AP may classify other changes in the Beacon frame as critical updates.

The non-AP STA shall attempt to receive the next Beacon frame when it receives a Check Beacon field that contains a value that is different from the previously received Check Beacon field.

The Address 1 field of the TIM frame shall be set to the broadcast address.

In a multiple BSSID set, the APs that do not correspond to the transmitted BSSID shall not transmit a TIM frame.

11.2.3.15 WNM sleep mode

11.2.3.15.1 WNM sleep mode capability

Implementation of the WNM sleep mode capability is optional for a WNM STA. A STA that implements WNM sleep mode has dot11WNMSleepModeImplemented equal to true. When dot11WNMSleepModeImplemented is true, dot11WirelessManagementImplemented shall be true. A STA where dot11WNMSleepModeActivated is true is defined as a STA that supports WNM sleep mode. A STA supporting WNM sleep mode shall set the WNM Sleep Mode field of the Extended Capabilities element to 1. When dot11WNMSleepModeActivated is true, dot11TFSActivated should be true.

A STA in which dot11WNMSleepModeActivated is true may send a WNM Sleep Mode Request or WNM Sleep Mode Response frame to a STA within the same infrastructure BSS whose last received Extended Capabilities element contained a value of 1 for the WNM Sleep Mode field in the Extended Capabilities field. WNM sleep mode is a service that may be provided by an AP to its associated STAs. The WNM sleep mode is not supported in an IBSS.

To prevent key reinstallation attacks, a non-AP STA in which dot11WNMSleepModeActivated is true shall maintain a copy of the most recent GTK, most recent IGTK and most recent BIGTK installed when exiting WNM sleep mode and shall not install a GTK, IGTK or BIGTK when the key to be set upon exiting WNM sleep mode matches any of the maintained keys (see 6.5.14).

WNM sleep mode enables an extended power save mode for non-AP STAs in which a non-AP STA need not listen for every DTIM beacon, and need not perform GTK/IGTK/BIGTK updates. A non-AP STA can sleep for extended periods as indicated by the WNM Sleep Interval field of the WNM Sleep Mode element, which is present in WNM Sleep Mode Request frames transmitted by the non-AP STA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.2.3.15.2 WNM sleep mode non-AP STA operation

To use the WNM sleep mode service, the non-AP STA's SME shall issue an MLME-SLEEPMODE.request primitive to send a WNM Sleep Mode Request frame. The MLME-SLEEPMODE.request primitive shall include a valid SleepMode parameter with a WNM Sleep Mode element. The Action Type field in the WNM Sleep Mode element shall be set to "Enter WNM sleep mode" and the WNM Sleep Interval field shall be included. The WNM Sleep Interval field shall be less than the BSS max idle period (see 11.21.13). The MLME-SLEEPMODE.request primitive may also include a valid TFSRequest parameter as defined in the TFS Request element that the AP shall use as triggers to set the STA's TIM bit.

When a traffic filter for group addressed frames is enabled at the AP, the STA may request a notification frame (see 11.21.12.2) be sent when requesting the establishment of the traffic filtering agreement.

On receiving a WNM Sleep Mode Response frame with Action Type field in the WNM Sleep Mode element set to "Exit WNM sleep mode", if dot11RSNAOperatingChannelValidationActivated is true and the AP's RSNE indicated OCVC, the STA shall validate the OCI information by ensuring that all the following are true:

— OCI element is present
— Channel information in the OCI matches current operating channel parameters (see 12.2.10)

Otherwise, the STA shall discard the frame.

The receipt of an MLME-SLEEPMODE.confirm primitive with a valid SleepMode parameter indicates to the STA's SME that the AP has processed the corresponding WNM Sleep Mode Request frame. The content of the WNM sleep mode parameter in the WNM Sleep Mode Response frame provides the status of WNM Sleep Mode elements processed by the AP. The non-AP STA shall delete the GTKSA if the response indicates success. If RSN is used with management frame protection, the non-AP STA shall delete the IGTKSA if the response indicates success. If RSN is used with beacon protection, the non-AP STA shall delete the BIGTKSA if the response indicates success.

While in WNM sleep mode, the non-AP STA need not transition to awake state every DTIM interval for group addressed frames.

The STA wakes up at intervals not longer than the value indicated by the WNM Sleep Interval field to check whether the corresponding TIM bit is set or group addressed traffic is pending. The non-AP STA does not participate in GTK/IGTK/BIGTK updates.

To exit WNM sleep mode, the non-AP STA's SME shall issue an MLME-SLEEPMODE.request primitive to send a WNM Sleep Mode Request frame with an Action Type field in the WNM Sleep Mode element set to "Exit WNM sleep mode". If dot11RSNAOperatingChannelValidationActivated is true and the AP's RSNE indicated OCVC, the WNM Sleep Mode Request frame shall include an OCI element.

If a STA receives an unsolicited WNM Sleep Mode Response frame with the WNM Sleep Mode Response status value (see Table 9-266) equal to 1, and the frame is not discarded due to OCI validation, the STA exits WNM sleep mode. If the STA does not receive a WNM Sleep Mode Response frame after sending a WNM Sleep Mode Request frame, it shall issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the current AP.

11.2.3.15.3 WNM sleep mode AP operation

On receiving a WNM Sleep Mode Request frame with Action Type field in the WNM Sleep Mode element set to "Exit WNM sleep mode", if dot11RSNAOperatingChannelValidationActivated is true and the non-AP STA's RSNE indicated OCVC, the AP shall validate the OCI information by ensuring that all the following are true:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— OCI element is present
— Channel information in the OCI fields matches current operating channel parameters (see 12.2.10)

Otherwise, the AP shall discard the frame.

When an AP's SME receives an MLME-SLEEPMODE.indication primitive with a valid SleepMode parameter and an Action Type in the WNM Sleep Mode element of "Enter WNM sleep mode" it shall issue an MLME-SLEEPMODE.response primitive with SleepMode parameters indicating the status of the request. The Action Type field of the WNM Sleep Mode element in the WNM Sleep Mode Response frame shall be set to "Enter WNM sleep mode".

When WNM sleep mode is enabled for an associated STA, the AP shall stop sending all individually addressed MPDUs to the non-AP STA. The AP may disassociate or deauthenticate the STA at any time for any reason while the non-AP STA is in WNM sleep mode. An AP shall perform the TFS AP operation, as specified in 11.21.12 for non-AP STAs for which it has received TFS Request elements. The AP shall set the TIM bit corresponding to the AID of the associated STA for which the AP has queued either a TFS Notify frame or matching frame. An AP shall not perform GTK/IGTK/BIGTK updates for the STAs in WNM sleep mode.

When an AP's SME receives an MLME-SLEEPMODE.indication primitive with a valid SleepMode parameter and an Action Type in the WNM Sleep Mode element of "Exit WNM sleep mode", if the frame is not discarded due to OCI validation, the AP shall disable WNM sleep mode service for the requesting STA, and the AP's SME shall issue an MLME-SLEEPMODE.response primitive with a SleepMode parameter indicating the status of the associated request. When all traffic filter sets established for a STA are deleted upon frame matches, the AP shall also disable the WNM sleep mode service and transmit to the STA an unsolicited WNM Sleep Mode Response frame with the WNM Sleep Mode Response status value (see Table 9-266) set to 1. When an AP sends a WNM Sleep Mode Response frame with Action Type field in the WNM Sleep Mode element set to "Exit WNM sleep mode", if dot11RSNAOperatingChannelValidationActivated is true and the non-AP STA's RSNE indicated OCVC, the WNM Sleep Mode Response frame shall include an OCI element.

If RSN is used with management frame protection and a valid PTK is configured for the STA, the current GTK, IGTK, and BIGTK shall be included in the WNM Sleep Mode Response frame. If a GTK/IGTK/BIGTK update is in progress, the pending GTK, IGTK, and BIGTK shall be included in the WNM Sleep Mode Response frame.

If RSN is used without management frame protection and a valid PTK is configured for the STA, the current GTK shall be sent to the STA using a group key handshake (see 12.7.7) immediately following the WNM Sleep Mode Response frame. If a GTK update is in progress, the pending GTK shall be sent to the STA using another group key handshake immediately after the current GTK has been sent.

11.2.3.16 VHT TXOP power save

A VHT AP supports the operation of non-AP VHT STAs in TXOP power save mode in a BSS when dot11VHTTXOPPowerSaveOptionImplemented is true. Non-AP VHT STAs that are in active mode and have dot11VHTTXOPPowerSaveOptionImplemented equal to true operate in TXOP power save mode. A STA that has dot11VHTTXOPPowerSaveOptionImplemented equal to true shall set the TXOP PS field in the VHT Capabilities element to 1; otherwise, the STA shall set the field to 0. A VHT AP may allow non-AP VHT STAs in TXOP power save mode to enter the doze state during a TXOP, which the AP does by transmitting a VHT PPDU with the TXVECTOR parameter TXOP_PS_NOT_ALLOWED set to 0. The value of this parameter in the TXVECTOR of all VHT PPDUs transmitted by the VHT AP may be changed from 1 to 0 during the TXOP to enable TXOP power save mode for the remainder of the TXOP. The value of this parameter in the TXVECTOR of all VHT PPDUs transmitted by VHT AP shall not be changed from 0 to 1 during the TXOP. If dot11VHTTXOPPowerSaveOptionImplemented at VHT AP is false then the VHT AP shall set the TXOP_PS_NOT_ALLOWED to 1 in the TXVECTOR of the frames with FORMAT VHT.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the AP allows non-AP VHT STAs to enter doze state during a TXOP, then a non-AP VHT STA that is in TXOP power save mode may enter the doze state until the end of that TXOP when one of the following conditions is met:

— On receipt of a VHT MU PPDU, the STA determines that it is not a member of the group indicated by the RXVECTOR parameter GROUP_ID.
— On receipt of an SU PPDU, the STA determines that the RXVECTOR parameter PARTIAL_AID is not equal to 0 nor does it match the STA's partial AID.
— The STA finds that the PARTIAL_AID in the RXVECTOR matches its partial AID but the RA in the MAC header of the corresponding frame that is received correctly does not match the MAC address of the STA.
— The STA receives a frame with an RXVECTOR parameter NUM_STS equal to 0 if it is a member of group indicated by RXVECTOR GROUP_ID.
— In a received VHT NDP Announcement frame, the STA finds that the RXVECTOR parameter PARTIAL_AID is 0 and the AID in the STA Info field is not its AID.
— The STA receives a QoS Data frame intended for it with the More Data subfield equal to 0 and No Ack ack policy or sends an acknowledgment if the ack policy is not No Ack.

The VHT AP shall include a nav-set sequence (e.g., RTS/CTS) (see G.4 at the beginning of such a TXOP with the Duration/ID value set to the remainder of the TXOP duration. A VHT AP shall not transmit frames to a non-AP VHT STA that has been allowed to enter doze state according to the conditions above for the remainder of the TXOP.

NOTE 1—A VHT AP does not transmit VHT SU PPDUs in the current TXOP if the AP has already transmitted a VHT PPDU with the TXVECTOR parameter TXOP_PS_NOT_ALLOWED set to 0 in the same TXOP and does not want the STAs that are in awake state to enter the doze state.

If a VHT AP truncates the TXOP in which it allowed STAs to enter doze state, then the VHT AP shall not transmit frames to the STAs that were allowed to enter the doze state until the NAV set at the start of the TXOP has expired.

Under all of the following conditions:

— An AP transmitted a PPDU;
— The PPDU contains individually addressed frame that contains all or part of an MSDU, A-MSDU or MMPDU;
— The frame is addressed to a non-AP VHT STA that is in TXOP power save mode;
— The frame's More Data subfield is 0;
— The transmitted PPDU's TXVECTOR parameter TXOP_PS_NOT_ALLOWED is 0;
— The AP did not receive an acknowledgment to this transmission;

then the AP shall retransmit that frame one or more times within the same TXOP, subject to applicable transmission restrictions. These restrictions include retry and lifetime limits, the TXOP limit and the rules on TXOP sharing (see 10.23.2.7). If an acknowledgment to the retransmission of this last frame in the same TXOP is not received, it may wait until the next TXOP to further retransmit that frame, subject to its applicable retry or lifetime limit.

NOTE 2—An AP that receives from a VHT STA in TXOP power save mode a BlockAck frame that is a response to an A-MPDU containing MPDUs with the More Data subfield equal to 0 cannot expect to receive a response to subsequent MPDUs retransmitted in the same TXOP because the VHT STA might be in the doze state.

A VHT STA that is in TXOP power save mode and has entered doze state shall continue to operate its NAV during doze state and shall transition into awake state on the expiration of the NAV.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 3—The STA can contend for access to the medium immediately on the expiration of the NAV.

11.2.3.17 AP power management

This subclause describes AP power management procedure for an S1G AP.

An AP with dot11APPMActivated equal to false or not present shall operate in the Active mode. An AP with dot11APPMActivated equal to true may operate in the following Power Management modes:

— Active
— Power save

An AP in active mode shall be in awake state and may receive frames at any time.

An AP with dot11APPMActivated equal to true in Power Save mode may be in any of the following two power states:

— Awake
— Doze

The AP with dot11APPMActivated equal to true may indicate that it is operating in Power Save mode by either:

— Setting the AP PM bit in the Frame Control field of the S1G Beacon frame to 1
— Including one or more RPS elements in the S1G Beacon frame that indicate AP PM RAWs (i.e., with the RAW Assignment Type equal to Simplex RAW and RAW Type Options equal to 0)

The AP shall operate in active mode during a beacon interval or short beacon interval if the AP PM subfield in the S1G Beacon frame transmitted at the TBTT or TSBTT is equal to 0. Similarly, the AP shall operate in active mode during one or more RAWs defined by an RPS element with the RAW Assignment type equal to generic RAW, sounding RAW, triggering frame RAW or simplex RAW with RAW Type Options equal to 1 or 2.

An AP that transmits an S1G Beacon frame with AP PM subfield equal to 1 may be in doze state at any time until the next TBTT or TSBTT, except that it shall be in awake state during any of the following intervals of time:

— Any RAW or PRAW intervals that are set up according to 10.23.5, except for RAWs that are defined by any RPS element with RAW Assignment Type equal to simplex RAW and RAW Type Options equal to 0
— Any TWT SPs that are negotiated according to 10.46

An AP that transmits an S1G Beacon frame whose AP PM subfield value is 1 should include an RPS element in the S1G Beacon frame that includes an omni RAW during which all STAs are allowed to access (i.e., the RPS element contains a RAW Assignment subfield with RAW Type field equal to 2 and RAW Type Options subfield equal to 2). The omni RAW may be used for association of new STAs. The AP that does not include the RPS element with the omni RAW, shall be awake for an amount of time not less than *bi* – *mad* immediately following the S1G Beacon frame, where *bi* is the beacon interval if dot11ShortBeaconInterval is false and is the short beacon interval if dot11ShortBeaconInterval is true, and *mad* is the dot11MaxAwayDuration.

An AP shall not be in doze state for a duration of time that exceeds the value of the dot11MaxAwayDuration. The AP shall set dot11MaxAwayDuration to the lowest value obtained from the Max Away Duration field that is contained in the most recently received MAD elements from any of its associated STAs.

An AP may reject a (re)association of a STA if the Max Away Duration field in the MAD element in the (Re)Association Request frame transmitted by the STA is considered unacceptable. For example, an AP that

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

schedules to be in doze state for 100 ms can reject association of a STA that indicates in the Association Request frame a value of 30 ms in its Max Away Duration field.

An AP may disassociate a STA based on the value indicated by Max Away Duration of the latest MAD element received from that STA.

An AP may include a MAD element in the (Re)Association Response frame or Probe Response frame that indicates the suggested maximum away duration during which the AP can be considered in doze state.

A STA may include a MAD element in the Probe Request or (Re)Association Request frames.

Irrespective of the Power Management mode and Power States, an AP shall maintain the synchronization of the network by generating beacons as described in 11.1.3.

A STA that is the intended receiver of a frame transmitted by an AP that has the PM Mode subfield equal to 0 shall consider the AP in active mode.

An AP that has previously sent a frame to one or a group of STAs with PM bit equal to 0, shall send a frame with PM bit equal to 1 to the same set of STAs before changing its operation mode to Power Save mode.

A STA that is the intended receiver of a frame transmitted by an AP that has the PM Mode subfield equal to 1 shall consider the AP in Power Save mode.

11.2.3.18 CMMG TXOP power save

A CMMG AP supports the operation of non-AP CMMG STAs in TXOP power save mode in a BSS when dot11CMMGTXOPPowerSaveOptionImplemented at the AP is true. Non-AP CMMG STAs that are in Active mode (see Table 11-5) and have dot11CMMGTXOPPowerSaveOptionImplemented equal to true operate in TXOP power save mode. A STA that has dot11CMMGTXOPPowerSaveOptionImplemented equal to true shall set the CMMG TXOP Power Save field in the CMMG Capabilities element to 1; otherwise, the STA shall set the field to 0. A CMMG AP may allow non-AP CMMG STAs in TXOP power save mode to enter the doze state during a TXOP. A CMMG AP shall indicate this by transmitting a CMMG PPDU with the TXVECTOR parameter TXOP_PS_NOT_ALLOWED set to 0. The value of this parameter in the TXVECTOR of all CMMG PPDUs transmitted by the CMMG AP may be changed from 1 to 0 during the TXOP to enable TXOP PS for the remainder of the TXOP. The value of this parameter in the TXVECTOR of all CMMG PPDUs transmitted by CMMG AP shall not be changed from 0 to 1 during the TXOP. If dot11CMMGTXOPPowerSaveOptionImplemented at CMMG AP is false then the CMMG AP shall set the TXOP_PS_NOT_ALLOWED to 1 in the TXVECTOR of the frames.

If the AP allows non-AP CMMG STAs to enter doze state during a TXOP, then a non-AP CMMG STA that is in CMMG TXOP power save mode may enter the doze state until the end of that TXOP when any of the following conditions is met:

— On receipt of a PPDU, the STA determines that the RXVECTOR parameter UPLINK_INDICATION is equal to 0, but the RXVECTOR parameter COLOR does not match the COLOR indicated by the AP to which the STA is associated.

— The STA finds that the COLOR in the RXVECTOR parameter matches the COLOR indicated by the AP to which the STA is associated but the RXVECTOR parameter PARTIAL_AID is not equal to 0 nor does it match the STA’s partial AID.

— The STA finds that the PARTIAL_AID in the RXVECTOR matches its partial AID but the RA in the MAC header of the corresponding frame that is received correctly does not match the MAC address of the STA.

— The STA receives a QoS Data frame intended for it with the More Data subfield equal to 0 and No Ack ack policy or sends an acknowledgment if the ack policy is not No Ack.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— On receipt of a PPDU, the non-AP STA determines that the RXVECTOR parameter UPLINK_INDICATION is equal to 1.

The CMMG AP shall include a NAV-set sequence (e.g., RTS/CTS) at the beginning of such a TXOP with the Duration/ID value set to the remainder of the TXOP duration. A CMMG AP shall not transmit frames to a non-AP CMMG STA that has been allowed to enter doze state according to the conditions above for the remainder of the TXOP.

NOTE 1—A CMMG AP does not transmit CMMG PPDUs in the current TXOP if the AP has already transmitted a CMMG PPDU with the TXVECTOR parameter TXOP_PS_NOT_ALLOWED set to 0 in the same TXOP and does not want the STAs that are in awake state to enter the doze state.

If a CMMG AP truncates the TXOP in which it allowed STAs to enter doze state, then the CMMG AP shall not transmit frames to the STAs that were allowed to enter the doze state until the NAV set at the start of the TXOP has expired.

If the AP does not receive an acknowledgment after transmitting an individually addressed frame containing all or part of an MSDU, A-MSDU, or MMPDU sent with the More Data field equal to 0 to a non-AP CMMG STA that is in CMMG TXOP power save mode and the AP had set the TXVECTOR parameter TXOP_PS_NOT_ALLOWED to 0, it shall retransmit that frame at least once within the same TXOP, subject to applicable retry, lifetime limit, or TXOP limit. If an acknowledgment to the retransmission of this last frame in the same TXOP is not received, it may wait until the next TXOP to further retransmit that frame, subject to its applicable retry or lifetime limit.

NOTE 2—An AP that receives from a CMMG STA in TXOP power save mode a BlockAck frame that is a response to an A-MPDU containing MPDUs with the More Data field equal to 0 cannot expect to receive a response to subsequent MPDUs retransmitted in the same TXOP because the CMMG STA might be in the doze state.

A CMMG STA that is in TXOP power save mode and has entered doze state shall continue to operate its NAV timer during doze state and shall transition into awake state on expiry of the NAV timer.

NOTE 3—The STA can contend for access to the medium immediately on the expiry of the NAV timer.

11.2.4 Power management in an IBSS

11.2.4.1 Introduction

Subclause 11.2.4 specifies the power management mechanism for use within an IBSS. This mechanism is deprecated.

11.2.4.2 Basic approach

A STA can be in one of two power management modes:

— Active mode: The STA receives and transmits frames at any time. The STA remains in the awake state.
— Power save (PS) mode: The STA enters the awake state to receive or transmit frames. The STA remains in the doze state otherwise.

The basic approach is similar to the infrastructure case in that the STAs are synchronized, and group addressed BUs and the BUs that are to be transmitted to a power-conserving STA are first announced during a period when all STAs are awake. The announcement is done via an ATIM frame sent in an ATIM window. A STA in the PS mode shall listen for these announcements to determine if it needs to remain in the awake state. The presence of the ATIM window in the IBSS indicates if the STA may use PS mode. To maintain correct

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

information on the power save state of other IBSS STAs, a STA needs to remain awake during the ATIM window. At other times the STA may enter the doze state except as indicated in the following procedures.

When a BU is to be transmitted to a destination STA that is in a PS mode, the transmitting STA first transmits an ATIM frame during the ATIM window, in which all of the STAs including those operating in a PS mode are awake. The ATIM window is defined as a specific period of time, defined by the ATIM Window field in the IBSS Parameter Set supplied to the MLME-START.request primitive, following a TBTT, during which only Control frames that are RTS, CTS, or Ack frames; Management frames that are Beacon or ATIM frames; or (QoS) Null frames shall be transmitted. ATIM frame transmission times are randomized, after a Beacon frame is either transmitted or received by the STA, using the backoff procedure with the CW equal to aCWmin. Individually addressed ATIM frames shall be acknowledged. If a STA transmitting an individually addressed ATIM frame does not receive an acknowledgment, the STA shall execute the backoff procedure for retransmission of the ATIM frame. Group addressed ATIM frames shall not be acknowledged.

If a STA receives an individually addressed ATIM frame during the ATIM window, it shall acknowledge the individually addressed ATIM frame and stay awake to receive the announced BUs for the entire beacon interval or until it has completed successful transmission to and reception from the source STA of the received ATIM frame, a frame with the EOSP subfield equal to 1. If a STA does not receive an ATIM frame, it may enter the doze state at the end of the ATIM window. Transmissions of BUs announced by ATIM frames are randomized after the ATIM window, using the backoff procedure described in Clause 10.

It is possible that an ATIM frame may be received from more than one STA, and that a STA that receives an ATIM frame may receive more than one BU from the transmitting STA. ATIM frames are only addressed to the destination STA of the BU.

An ATIM frame for a BU shall have a destination address identical to that of the BU.

After the ATIM interval, only individually addressed BUs that have been successfully announced with an acknowledged ATIM frame and group addressed BUs that have been announced with an ATIM frame shall be transmitted to STAs in the PS mode. These frames shall be transmitted using the DCF (for non-QoS STAs) or EDCAF (for QoS STAs).

Figure 11-17 illustrates the basic PS operation.

The estimated power saving state of another STA may be based on the power management information transmitted by that STA and on additional information available locally, such as a history of failed transmission attempts. The use of RTS/CTS in an IBSS may reduce the number of transmissions to a STA that is in PS mode. If an RTS frame is sent and a CTS frame is not received, the transmitting STA may assume that the destination STA is in PS mode. The method of estimating the power management state of other STAs in the IBSS is outside the scope of this standard.

11.2.4.3 Initialization of power management within an IBSS

The following procedure shall be used to initialize power management within a new IBSS, or to learn about the power management being used within an existing IBSS:

a) A STA joining an existing IBSS by the procedure in 11.1.4.4 shall update its ATIM window with the value contained in the ATIM Window field of the IBSS Parameter Set element within the Beacon or Probe Response frame received during the scan procedure.

b) A STA starting a new IBSS by the procedure in 11.1.4.4 shall set the ATIM Window field of the IBSS Parameter Set element within the Beacon frames transmitted to the value of its ATIM window.

c) The start of the ATIM window shall be the TBTT, defined in 11.1.3.5. The end of the ATIM window shall be defined as

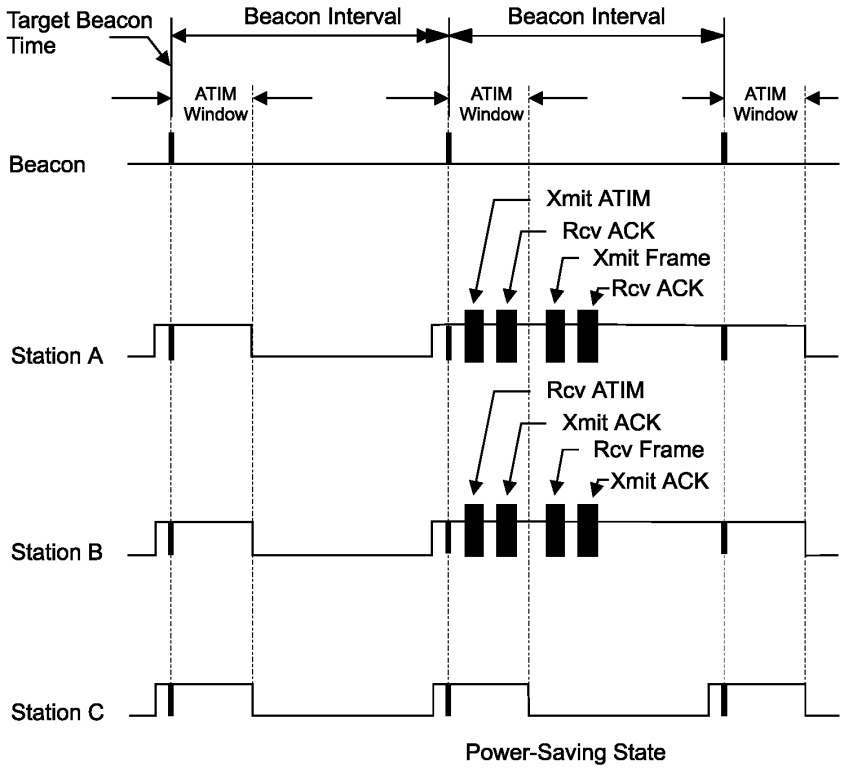

Figure 11-17—Power management in an IBSS—basic operation

TSF timer mod dot11BeaconPeriod = ATIMWindow,
where ATIMWindow is the ATIM Window field of the IBSS Parameter Set from the MLME-START.request or MLME-JOIN.request primitives.

d) The ATIM window period shall be static during the lifetime of the IBSS.

e) An ATIM window value of 0 shall indicate that power management is not usable within the IBSS.

11.2.4.4 STA power state transitions

A STA may enter PS mode if the value of the ATIM window in use within the IBSS is greater than 0. A STA shall not enter PS mode if the value of the ATIM window in use within the IBSS is equal to 0.

A STA shall indicate its power management mode in the Power Management subfield of the Frame Control field of frames containing all or part of a BU or individually addressed Probe Request frame, or (QoS) Null frames, that it transmits.

A STA in PS mode shall transition between awake state and doze state according to the following rules:

a) If a STA is operating in PS mode, it shall enter the awake state prior to each TBTT.

b) If a STA receives a group addressed ATIM frame during the ATIM window, the STA shall remain in the awake state until either the STA receives a group addressed frame from the source STA with the EOSP subfield equal to 1 or the end of the next ATIM window, whichever occurs first.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

c) If a STA receives at least one individually addressed ATIM frame containing the STA's individual address in the RA field during the ATIM window then the STA shall remain in the awake state at least until the earlier of the completion of the successful transmission to and reception from the source STA of each received ATIM frame, a frame with the EOSP subfield equal to 1, and the end of the next ATIM window.

d) If a STA transmits at least one individually addressed ATIM frame containing a STA's individual address in the RA field during the ATIM window then the STA shall remain in the awake state at least until the earlier of the completion of the successful transmission to and reception from the destination STA of each transmitted ATIM frame, a frame with the EOSP subfield equal to 1, and the end of the next ATIM window.

e) If a STA transmits a Beacon, the STA shall remain in the awake state until the end of the next ATIM window.

f) If the STA has not transmitted an ATIM frame and does not receive either an individually addressed ATIM frame containing the STA's individual address, or a group addressed ATIM frame during the ATIM window, the STA may return to the doze state following the end of the current ATIM window.

11.2.5 Power management in an MBSS

Power management in an MBSS is described in 14.15.

11.2.6 SM power save

A STA consumes power on all active receive chains, even though they are not necessarily required for the actual frame exchange exchange. The SM power save feature allows a non-AP HT STA or a non-AP and non-PCP EDMG STA in an infrastructure BSS or PBSS to operate with only one active receive chain for a significant portion of time.

The STA controls which receive chains are active through the PHY-RXCONFIG.request primitive specifying a PHYCONFIG_VECTOR parameter ACTIVE_RXCHAIN_SET that indicates which of its receive chains should be active.

The basic rules for a STA are defined below. Additional rules for an HE STA in dynamic SM power save mode that sets the HE Dynamic SM Power Save subfield to 1 in the HE MAC Capabilities Information field in the HE Capabilities element it transmits are defined in 26.14.4.

In dynamic SM power save mode, the HT STA enables its multiple receive chains when it receives the start of a frame exchange sequence addressed to it, while the EDMG STA enables its multiple receive chains only when the frame it receives indicates that the following transmission requires the activation of multiple receive chains (see 10.38.12.4). Such a frame exchange sequence shall start with a single-spatial stream individually addressed frame that is not a Trigger frame, that requires an immediate response and that is addressed to the STA in dynamic SM power save mode. For an HT STA, an RTS/CTS sequence may be used for this purpose. For an EDMG STA in dynamic SM power save mode, a Grant/Grant Ack sequence shall be used for this purpose (see 10.38.12.4.2 (MIMO channel access rules)). The STA shall, subject to its spatial stream capabilities (see 9.4.2.54.4 and 9.4.2.156.3) and operating mode (see 11.40), be capable of receiving a PPDU that is sent using more than one spatial stream a SIFS after the end of the PPDU it sends as the immediate response. The STA may switch back to the single receive chain mode immediately after the end of the frame exchange sequence.

NOTE—An HT STA in dynamic SM power save mode cannot distinguish between an RTS/CTS sequence that precedes a MIMO transmission and any other RTS/CTS and, therefore, always enables its multiple receive chains if it responds to the RTS addressed to it.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The STA determines the end of the frame exchange sequence through any of the following:

- It receives an individually addressed frame addressed to another STA.
- It receives a frame with a TA that differs from the TA of the frame that started the TXOP.
- It receives a PPDU and classifies the PPDU as inter-BSS PPDU (see 26.2.2).
- It receives an HE MU PPDU where the RXVECTOR parameter BSS_COLOR is the BSS color of the BSS in which the STA is associated, the RXVECTOR parameter does not have any STA_ID of an RU that identifies the STA as the recipient or one of the recipients of the RU (see 26.11.1), and the BSS Color Disabled subfield in the most recently received HE Operation element from the AP with which the STA is associated is 0.
- The CS mechanism (see 10.3.2.1) indicates that the medium is idle at the TxPIFS slot boundary (defined in 10.3.7).

In static SM power save mode, the STA maintains only a single receive chain active.

The STA may use the SM Power Save frame to communicate its SM power save state. The STA may also use the SM Power Save subfield in the HT Capabilities element or EDMG Capabilities element of its (Re)Association Request frame or the SM Power Save subfield in the HE 6 GHz Band Capabilities element of its (Re)Association Request frame to achieve the same purpose. Using the (Re)Association Request frame allows the STA to use only a single receive chain immediately after (re)association.

A STA that has one or more TDLS direct links shall not operate in SM power save mode.

Changes to the number of active receive chains are made only after the SM power save mode indication has been successfully delivered (i.e., by acknowledgment of a frame carrying the HT Capabilities element or EDMG Capabilities element, by acknowledgment of a frame carrying the HE 6 GHz Band Capabilities element, or by acknowledgment of an SM Power Save frame). The SM power save mode indication shall be transmitted using an individually addressed frame.

11.2.7 Power management in a PBSS and DMG infrastructure BSS

11.2.7.1 General

Power save mechanisms in this subclause enable non-AP STAs to sleep for one or more beacon intervals or for parts of a beacon interval.

The non-AP and non-PCP STA power save mechanisms defined in 11.2.7.2 enable a non-AP and non-PCP STA to transition to doze state after signaling the AP or PCP, or to remain in doze state according to a periodic schedule that is negotiated with the AP or PCP. A non-AP and non-PCP STA may use both mechanisms in conjunction to increase its power save opportunity.

Similarly, the PCP power save mechanisms defined in 11.2.7.3 enable a PCP to transition to doze state after signaling at least one non-AP and non-PCP STA, or to remain in doze state according to a wakeup schedule that is available to all STAs associated with the PCP.

A non-AP STA can be in one of two power management modes:

- Active mode: The STA does not use any of the scheduled or unscheduled power save mechanisms defined in this subclause and operates in the awake state, except during time intervals that it determines it is not the target of any transmission by other STAs, where it may operate in doze state.
- Power save (PS) mode: The STA uses at least one of the scheduled or unscheduled power save mechanisms defined in this subclause and switches between awake and the doze states.

A non-AP STA shall be in active mode upon (re)association.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

For scheduled power save, the DMG Wakeup Schedule element (9.4.2.129) is used to communicate the transitions between doze and awake states of a DMG STA, referred to as the STA *wakeup schedule (WS)*. A STA wakeup schedule defines a periodic routine of cycling between a set of contiguous beacon intervals referred to as awake beacon intervals (A-BIs) and a set of contiguous beacon intervals referred to as doze beacon intervals (D-BIs). The rules for alternating between awake and doze power states during A-BIs and D-BIs are defined in 11.2.7.2.3 and 11.2.7.3.3. An overview of these rules is given in Table 11-5 and Table 11-6.

A STA in PS mode that is following a wakeup schedule and has also exercised unscheduled power save shall follow the D-BI rules in this subclause and shall follow the ATIM rules in 11.2.7.4 for a non-AP STA without wakeup schedule.

An AP or PCP keeps track of the wakeup schedules of all associated non-AP and non-PCP STAs. A non-AP and non-PCP STA keeps track of the wakeup schedule of all associated non-AP and non-PCP STAs that it is communicating with. There is no end time to a wakeup schedule. Once a STA enters PS mode according to its wakeup schedule it stays indefinitely in PS mode until it leaves the PS mode through mechanisms defined in this subclause. Once a STA is made aware of the wakeup schedule of another STA, it is able to keep track of the wakeup schedule on its own. Each STA delivers traffic to a peer STA only when the peer STA is in awake state.

A STA that has transmitted a frame to an AP or PCP with which it is not associated and from which it expects a response shall remain in the awake state until such a response is received or until the procedure has timed out.

An AP shall buffer BUs addressed to non-AP STAs in doze state. The buffered BUs shall be transmitted only at designated times (11.2.7.2). A non-AP STA shall defer delivery of BUs addressed to other non-AP STAs in doze state. The BUs shall be transmitted only at designated times (11.2.7.2).

If a PCP sets the BSS Type field within a transmitted DMG Beacon frame to PBSS or the AP or PCP includes a Nontransmitted BSSID Capability element in a transmitted DMG Beacon, Announce, or Probe Response frames and the BSS Type field within the Nontransmitted BSSID Capability element is equal to PBSS, then the AP or PCP shall follow the PCP power management rules described in 11.2.7.3 if the AP or PCP chooses to employ power management.

An AP or PCP may include an Antenna Sector ID Pattern element in Power Save Configuration Response and Probe Response frames transmitted to a non-AP and non-PCP STA. If a non-AP and non-PCP STA uses the information contained in the Antenna Sector ID Pattern element received from its AP or PCP, then during the BTI of an A-BI, the STA might stay awake just to receive DMG Beacon frames transmitted through specific DMG antenna and sector and switch to doze state during other periods in the BTI.

Table 11-5 lists the power states for a non-AP and non-PCP STA in PS mode and a PCP in PS mode during an A-BI. Each entry indicates the state, either awake or doze, for the non-AP and non-PCP STA or the PCP in PS mode at various times during the A-BI.

Table 11-5—Power states for an A-BI

	Unassigned TDD slot	Awake or doze	Doze
	Assigned simplex RX TDD slot	Awake	Awake
	Assigned simplex TX TDD slot	Awake	Awake or doze

Table 11-6 lists the power states for a non-AP and non-PCP STA in PS mode and a PCP in PS mode during a D-BI. Each entry indicates the state, either awake or doze, for the non-AP and non-PCP STA or the PCP in PS mode at various times during the D-BI.

The source DMG STA and the destination DMG STA of a nontruncatable SP, allocated CBAP, or TDD slot with a destination AID that is not the broadcast AID may go to doze state within the SP, within the CBAP, or within the TDD slot, respectively, after the source DMG STA transmitted a frame to the destination DMG STA of the SP, the CBAP, or the TDD slot, respectively, with the EOSP subfield set to 1 and received the following response frame from the destination DMG STA of the SP, the CBAP, or the TDD slot, respectively.

If the MM-SME Power Mode field within the MMS element sent by an MM-SME coordinated STA is 1, all STAs advertised in the MMS element shall switch to the doze state when the wakeup schedule of any one STA or a successful frame exchange sequence brings the STA to the doze state.

If the MM-SME Power Mode field within the MMS element sent by an MM-SME coordinated STA is 0, all STAs advertised in the MMS element shall switch to the awake state when the wakeup schedule of any one STA or a successful frame exchange sequence as described in Annex G brings the STA to the awake state.

11.2.7.2 Non-AP and non-PCP STA power management mode

11.2.7.2.1 General

The power management mode of a non-AP and non-PCP STA is selected by the PowerManagementMode parameter of the MLME-POWERMGT.request primitive. Once the STA updates its power management mode, the MLME shall issue an MLME-POWERMGT.confirm primitive indicating the result of the operation. While the STA is in PS mode it may exercise the unscheduled and scheduled power save mechanisms described in this subclause.

Figure 11-18 illustrates a finite state machine that shows the state transition of a STA in active and PS mode, and also the transition between active and PS modes when the non-AP and non-PCP STA has set up a wakeup schedule.

NOTE—In Figure 11-18 , the notations PSC-REQ(X) and PSC-RSP(Y) indicate that the PSC-REQ and PSC-RSP frames, respectively, are transmitted with the setting as indicated by their corresponding X and Y parameters. The transitions shown “As per T1” are defined in Table 11-5. The transitions shown “As per T2” are defined in Table 11-6.

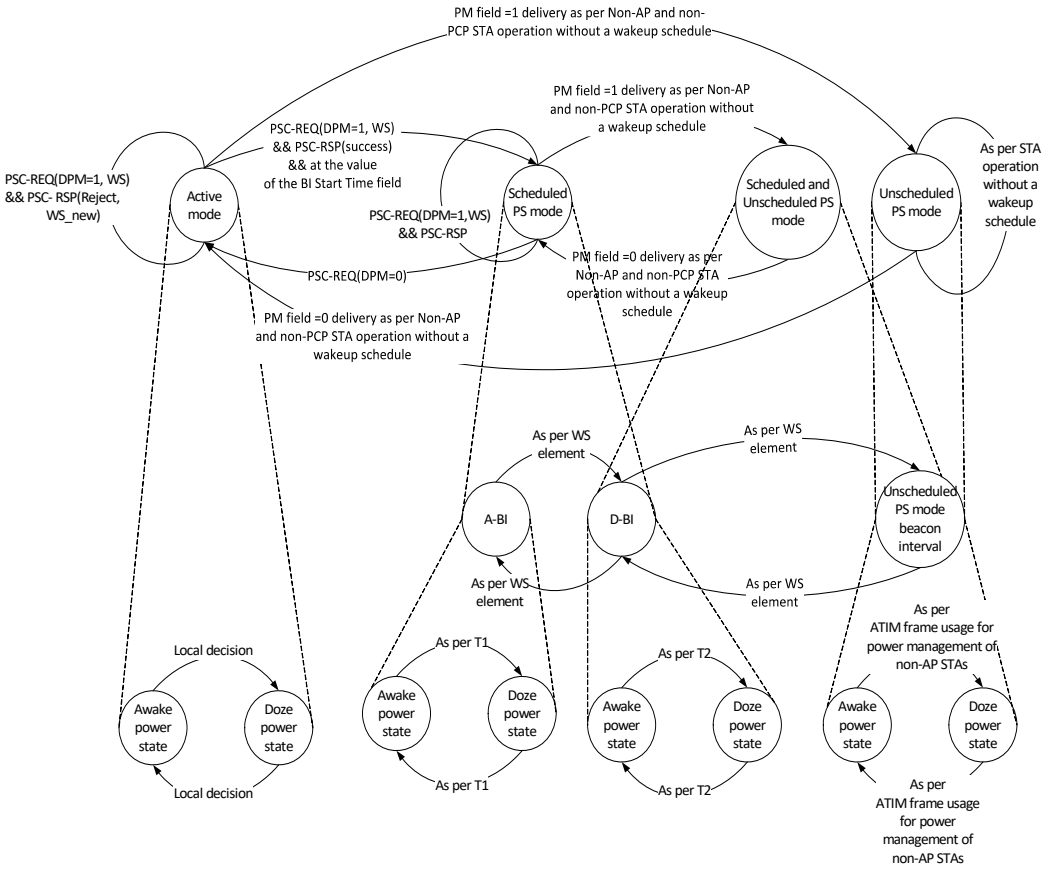

Figure 11-18—State transition diagram of non-AP and non-PCP STA in active and PS modes

11.2.7.2.2 Non-AP and non-PCP STA operation without a wakeup schedule

To change its power state without a wakeup schedule, a non-AP and non-PCP STA shall inform the AP or PCP by completing a successful frame exchange that is initiated by the STA and that includes a Management frame, Extension frame or Data frame, and also an Ack or a BlockAck frame from the AP or PCP. The Power Management subfield(s) in the Frame Control field of the frame(s) sent by the STA in this exchange that are acknowledged by the AP or PCP indicate the power state that the STA shall adopt upon successful completion of the frame exchange sequence, except where the Power Management subfield is reserved (see 9.2.4.1.7). A non-AP and non-PCP STA shall not change its power state using a frame exchange sequence that does not receive an Ack or BlockAck frame from the AP or PCP, or using a BlockAckReq frame.

A non-AP and non-PCP STA in doze state shall limit the frames it transmits to the following:

— A Management, Extension or Data frame that triggers an Ack or a BlockAck frame from the AP or PCP, with the Power Management subfield in the Frame Control field of the frame set to 0, i.e., a frame to indicate the STA intent to transition out of unscheduled PS mode.

— A Management, Extension or Data frame that triggers an Ack or a BlockAck frame from the AP or PCP, plus Ack and BlockAck frames that respond to the frames sent by the AP or PCP during the reverse direction grant, if the following conditions apply:

  — The Power Management subfield in the Frame Control field of the frame sent by the non-AP and non-PCP STA is set to 1.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

  - The AP or PCP has transmitted a Capability Information field in which the Triggered Unscheduled PS subfield is equal to 1.
- An RTS, DMG CTS-to-self, CF-End, Grant, BRP, SSW or SSW-Feedback frame.

NOTE 1—A DMG STA in doze state might need to perform beamforming to restore its links with other DMG STAs.

As long as there is at least one STA that has entered doze state through the unscheduled power save mechanism, the AP or PCP shall establish at least one awake window by transmitting an Awake Window element, and shall include a UPSIM element in every DMG Beacon and Announce frame it transmits. The AP or PCP may establish awake windows and/or include a UPSIM element in a DMG Beacon or Announce frame it transmits even if no STA is in doze state. The absence of a UPSIM element in a DMG Beacon or Announce frame is equivalent to presence of the UPSIM element in the frame with all bits of the Power Save Indication Bitmap field in the UPSIM element set to 0. The UPSIM element in every DMG Beacon or Announce frame transmitted by the AP or PCP shall indicate the power state of all STAs at the time of frame transmission.

NOTE 2—Transmitting a DMG Beacon frame with the Discovery Mode subfield set to 0, or an Announce frame, without including the UPSIM element in the frame, indicates that no STA is in unscheduled PS mode at the time of the frame transmission.

A non-AP and non-PCP STA may also indicate its power state to another non-AP and non-PCP STA through the Power Management subfield in the Frame Control field of any frame that contains all or part of a BU. The non-AP and non-PCP STA shall indicate its correct power state in the Frame Control field of any frame it transmits that contains all or part of a BU.

When a non-AP and non-PCP STA that has not set up a wakeup schedule with the AP or PCP enters PS mode, every beacon interval shall be an A-BI for that STA. A non-AP and non-PCP STA that has not set up a wakeup schedule with the AP or PCP and that is in PS mode shall be awake during any allocated SP for which the STA is either the source DMG STA or destination DMG STA during an A-BI. During an A-BI, a non-AP and non-PCP STA that has not set up a wakeup schedule with the AP or PCP and that is in PS mode shall be awake during any allocated CBAP for which the STA is the source DMG STA or destination DMG STA, or the source AID of the CBAP is equal to the broadcast AID or the destination AID of the CBAP is equal to the broadcast AID.

A non-PCP and non-AP STA that is in the doze state may offer an RDG to its AP or PCP if the following conditions apply:

- The AP or PCP has transmitted a Capability Information field in which the Triggered Unscheduled PS field is equal to 1.
- The non-AP and non-PCP has transmitted a Capability Information field in which the Reverse Direction subfield is equal to 1.

The AP or the PCP may use the offered RDG to transmit one or more BUs to the non-PCP and non-AP STA using the reverse direction protocol defined in 10.29.

The non-PCP and non-AP STA should continue to offer an RDG to the AP or to the PCP within the current TXOP while the Buffered AC subfield of the QoS Control field in frames transmitted by the AP or by the PCP indicates that one or more BUs are buffered for the AC for which the TXOP was gained.

An EDMG AP shall set the Triggered Unscheduled PS subfield to one in any transmitted Capability Information field. A non-AP EDMG STA may set the Triggered Unscheduled PS subfield to one in any transmitted Capability Information field. An EDMG STA is QoS triggered enabled if it transmits a Triggered Unscheduled PS subfield equal to 1.

An EDMG STA may include the QoS Triggered Unscheduled element in a PSC-REQ or Association Request frame transmitted to an QoS triggered enabled EDMG AP or EDMG PCP to indicate an explicit

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

request for a QoS triggered unscheduled power save on specific ACs. A QoS triggered enabled EDMG AP or EDMG PCP shall include a QoS Triggered Unscheduled element in the PSC-RSP or Association Response frame, respectively, sent as response with the same QoS-TU AC flag fields set to 1 as those that were set to 1 in the received PSC-REQ or Association Request frame. An EDMG STA may clear the QoS triggered unscheduled power save on a specific AC by sending a successful PSC-REQ frame with the relevant QoS-TU AC flag field set to 0.

When QoS triggered unscheduled power save is enabled on a specific AC, an EDMG PCP and an EDMG AP shall deliver the available buffered BU on the AC immediately following a trigger frame that grants the RDG to the EDMG PCP or EDMG AP. The EDMG PCP or EDMG AP shall not deliver to the triggering STA an A-MPDU with a size greater than indicated by the QoS-TU Max A-MPDU Length Exponent field and the A-MPDU shall not contain more MPDUs than the number of MPDUs indicated by the QoS-TU Max MPDU Size field, where both of these fields are indicated in the last QoS Triggered Unscheduled element sent in the PSC-REQ frame or Association Request frame, whichever came later, that established the QoS triggered unscheduled power save.

11.2.7.2.3 Non-AP and non-PCP STA operation with a wakeup schedule

To transition from active mode to PS mode, a non-AP and non-PCP STA that is associated with an AP or PCP shall establish a wakeup schedule (WS) with the AP or PCP. A WS is established with the AP or PCP following the successful transmission of a PSC-REQ frame to the AP or PCP with the DPM field set to 1 and an acknowledged receipt of the corresponding PSC-RSP frame from the AP or PCP provided that the PSC-RSP frame contained a status code indicating success. After receiving a PSC-RSP frame from the AP or PCP with a status code indicating success and responding with an acknowledgment, the STA switches to the PS mode at the instant specified by the BI Start Time field of the DMG Wakeup Schedule element transmitted to the AP or PCP. In PS mode, the STA shall cycle between A-BIsand D-BIs following the WS that the STA has established with the AP or PCP.

As long as there is at least one STA that is in PS mode, the AP or PCP shall establish an awake window. The AP or PCP may include an Awake Window element in a DMG Beacon or Announce frame it transmits even if no STA in the BSS has entered PS mode.

A DMG Wakeup Schedule element shall be included in any PSC-REQ frame that the STA transmits to the AP or PCP as an explicit request for a WS. An Awake Window element may also be included in the same PSC-REQ frame to indicate a requested duration for the awake window. If the AP or PCP accepts the proposed WS and the optionally present awake window duration in the PSC-REQ frame, it shall reply with a PSC-RSP frame indicating a status code of SUCCESS. Otherwise, it shall respond with a PSC-RSP frame with a status code indicating the reason for rejecting the request. The AP or PCP may suggest an alternative WS and optionally an awake window duration in the PSC-RSP frame and set the status code to REJECT_WITH_SCHEDULE. If the STA accepts the alternative WS, it shall include this WS in a subsequently transmitted PSC-REQ frame. If the non-AP and non-PCP STA does not accept the alternative WS, it shall not send a PSC-REQ frame for dot11PSRequestSuspensionInterval beacon intervals following the receipt of the PSC-RSP frame from the AP or PCP.

NOTE 1—The AP or PCP can recommend an alternative WS, for example, to align the A-BIs of some or all non-AP and non-PCP STAs.

NOTE 2—The awake window duration sent by the AP or PCP in a PSC-RSP frame is to assist the STA for awake window planning. The awake window duration is always set by the Awake Window element in the most recent DMG Beacon or Announce frame received from the AP or PCP.

If a non-AP and non-PCP STA has established a WS with the AP or PCP and the non-AP and non-PCP STA is in PS mode, the non-AP and non-PCP STA shall have *m* successive A-BIs repeating every *n* beacon interval, where *n* is the Sleep Cycle field of the DMG Wakeup Schedule element contained in the PSC-RSP frame received from the AP or PCP during the frame exchange sequence that established the WS, and *m* is the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Number of Awake BIs field in the DMG Wakeup Schedule element contained in that PSC-RSP frame. During each of its A-BIs, the non-AP and non-PCP STA shall be awake during the awake windows that are present, and during all allocated SPs in which it is either the source or destination DMG STA.

An AP or PCP may send an unsolicited PSC-RSP frame without a WS and indicating a status code of success to a non-AP and non-PCP STA in PS mode. Upon receiving the unsolicited PSC-RSP frame meeting these conditions, the non-AP and non-PCP STA shall switch to active mode.

11.2.7.2.4 Non-AP and non-PCP STA operation with or without a wakeup schedule

A non-AP and non-PCP STA in PS mode shall stay awake for dot11MinBHIDuration starting from the beginning of each A-BI and may switch to the doze state after the expiration of this time. The only exception is when the Power Save Configuration Response or Probe Response frame received from the AP or PCP includes an Antenna Sector ID Pattern element, in which case the non-AP and non-PCP STA may use the Antenna Sector ID Pattern element to receive DMG Beacon frames transmitted through a specific DMG antenna and sector, and may switch to doze state during other periods in the BTI.

An AP or PCP shall transmit SP allocation announcements for STAs in PS mode during each of the STAs' A-BIs and may transmit those SP allocation announcements in other beacon intervals. New SPs shall be allocated to begin either within or after the later A-BI of the source DMG STA and destination DMG STA of the SP.

To transition from PS mode to active mode, a non-AP and non-PCP STA that has an established WS with the AP or PCP shall send a PSC-REQ frame with the DPM field set to 0 to the AP or PCP and enter active mode following the reception of the Ack frame response. The AP or PCP shall not send a PSC-RSP frame if the DPM field is 0 in the PSC-REQ frame.

In order for a STA to learn the WS of another STA within the BSS, the STA may send an Information Request frame to the other STA or to the AP or PCP as defined in 11.28.1. The AP or PCP maintains a WS distribution table for the lifetime of the BSS, and upon receiving an Information Request frame that contains a request for the WS of a STA identified by the Subject Address field within the frame, shall add an entry to the WS distribution table made up of the STA that transmitted the Information Request frame (the requesting STA) and the STA identified by the Subject Address field within the Information Request frame (the target STA). If the AP or PCP moves the TBTT, changes the duration of the beacon interval, or resets the TSF, the AP or PCP shall transmit an unsolicited Information Response frame with the updated DMG Wakeup Schedule element. When transmitting the DMG Wakeup Schedule element for a STA that is in PS mode, the transmitting STA shall use a value for the BI Start Time field that points to a TBTT that is earlier, but not more than 2^{31} μs minus aDMGDWSValidPeriod earlier, than the TBTT of the beacon interval during which the BI Start Time field is transmitted, so that the receiving STA can correctly identify the power management mode of the STA to which the WS belongs.

If the Information Request frame is transmitted to the AP or PCP and the STA indicated in the Information Request's Subject Address field does not have an established WS with the AP or PCP, the AP or PCP shall set the length of the DMG Wakeup Schedule element to 0 in the Information Response frame.

11.2.7.3 PCP power management mode

11.2.7.3.1 General

The power management mode of a PCP is selected by the PowerManagementMode parameter of the MLME-POWERMGT.request primitive. Once the PCP updates its power management mode, the MLME shall issue an MLME-POWERMGT.confirm primitive indicating the result of the operation. While the PCP is in PS mode it may exercise the unscheduled and scheduled power save mechanisms described in this subclause.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.2.7.3.2 PCP operation without a wakeup schedule

To change its power state without a wakeup schedule, the PCP shall include a UPSIM element in or remove the UPSIM element from every DMG Beacon frame with the Discovery Mode subfield set to 0 and Announce frame that it transmits, and shall indicate its new power state in the UPSIM element if it is included in the frame

NOTE 1—The UPSIM element in a DMG Beacon frame with the Discovery Mode subfield set to 0, or in an Announce frame, includes the power state of the PCP at the time of the frame transmission. Transmitting a DMG Beacon frame with the Discovery Mode subfield set to 0 or an Announce frame, without including the UPSIM element in the frame, indicates that no STA (including the PCP) is in unscheduled PS mode at the time of the frame transmission.

Alternatively, to change its power state without a wakeup schedule, the PCP shall inform all associated STAs by completing a successful frame exchange sequence that is initiated by the PCP and that includes a Management frame, Extension frame or Data frame, and also an Ack or a BlockAck frame from the associated STA. The Power Management subfield(s) in the Frame Control field of the frame(s) sent by the PCP in this exchange that are acknowledged by the PCP indicate the power state that the PCP shall adopt upon successful completion of the frame exchange sequence, except where the Power Management subfield is reserved (see 9.2.4.1.7) The PCP shall not change its power state using a frame exchange sequence that does not receive an Ack or BlockAck frame from the associated STA, or using a BlockAckReq frame.

The PCP shall not enter doze state unless it has received an Ack or BlockAck from each associated STA. The PCP shall enter awake state as soon as it receives an Ack or BlockAck from one associated STA.

A PCP in doze state shall limit the frames it transmits to the following:

- A Management, Extension or Data frame that triggers an Ack or a BlockAck frame from a non-AP and non-PCP STA, with the Power Management subfield in the Frame Control field of the frame set to 0, i.e., a frame to indicate the PCP intent to transition out of unscheduled PS mode.
- A Management, Extension or Data frame that triggers an Ack or a BlockAck frame from a non-AP and non-PCP STA, plus Ack and BlockAck frames that respond to the frames sent by the non-AP and non-PCP STA during the reverse direction grant, if the following conditions apply:
  - The Power Management subfield in the Frame Control field of the frame sent by the PCP is set to 1.
  - The non-AP and non-PCP STA has transmitted a Capability Information field in which the Triggered Unscheduled PS subfield is equal to 1.
- An RTS, DMG CTS-to-self, CF-End, Grant, BRP, SSW or SSW-Feedback frame.

NOTE 2—A DMG STA in doze state might need to perform beamforming to restore its links with other DMG STAs.

The PCP shall indicate the correct power state in the Frame Control field of any frame it transmits to an associated STA that contains all or part of a BU.

11.2.7.3.3 PCP operation with a wakeup schedule

A PCP in PPS mode (PPS PCP) may enter the doze state for one or more consecutive beacon intervals in order to minimize its energy consumption. Figure 11-19 illustrates a finite state machine that shows the state transition of the PCP power management mode.

NOTE 1—Figure 11-19 uses the following terminology: “As per T1” means that the transitions are specified in Table 11-5, “As per T2” means that the transitions are specified in Table 11-6.

To enter PPS mode, or to modify an established WS, the PCP announces a WS through a DMG Wakeup Schedule element (9.4.2.129) included in a DMG Beacon, Announce, or any Action frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

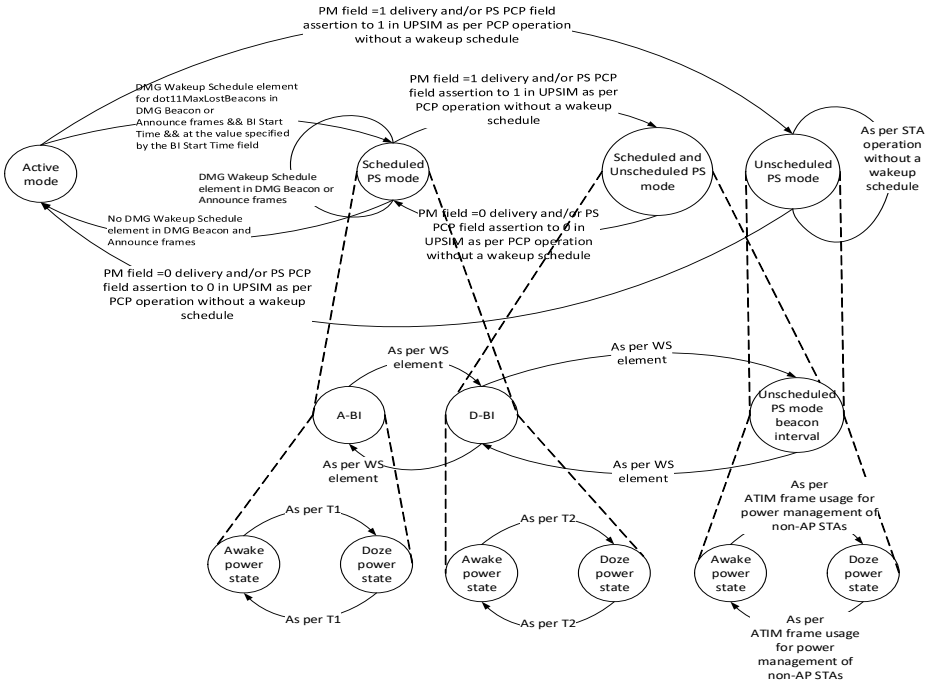

Figure 11-19—State transition diagram of PCP power management mode

The PCP can assume that all associated STAs have received a WS and the Awake Window element that can optionally be transmitted with the WS at the earlier of the following events:

— The PCP has transmitted the DMG Wakeup Schedule element in DMG Beacon or Announce frames for at least dot11MaxLostBeacons successive beacon intervals.

— The PCP has confirmed that each associated STA has received the DMG Wakeup Schedule element by receiving an ACK or a response frame from each associated STA in response to a request frame that includes the DMG Wakeup Schedule element.

The first PCP A-BI of a sleep cycle in a WS starts at the instant specified by the BI Start Time field of the announced DMG Wakeup Schedule element, and the number of successive PCP A-BIs is specified by the Number of Awake BIs field of the DMG Wakeup Schedule element.Once in PPS mode, the PCP transitions between A-BI and D-BI according to the WS it has established.

NOTE 2—The PCP might need to behave as if it is in active mode or in an A-BI to some associated STAs for a number of planned successive PCP D-BIs if it has not been able to confirm the reception of its WS by each associated STA, and it has not transmitted its WS through DMG Beacon or Announce frames over dot11MaxLostBeacons successive beacon intervals.

In order to transition from PPS mode to active mode, the PCP stops including the DMG Wakeup Schedule element in DMG Beacon and Announce frames. A DMG STA that receives a PCP WS shall assume the PCP WS is in effect until it either receives a DMG Beacon or Announce frame that does not include a DMG Wakeup Schedule element or receives a different PCP WS.

In a PCP D-BI, the PCP should schedule a BTI or ATI. If scheduling an ATI, the PCP should transmit an Announce frame during the ATI to associated STAs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 3—The PCP provides the PBSS timing synchronization function (TSF). Transmitting frequent TSF information through DMG Beacon or Announce frames is important when there are non-PCP STAs in the PBSS that rely on TSF information to communicate directly with each other.

The PCP may include in the Extended Schedule element the schedule for the beacon intervals during the PCP D-BIs. The PCP may schedule an SP or CBAP within a D-BI by setting the Allocation Start field of the new SP or CBAP in the Extended Schedule element to a value within a D-BI. If the Extended Schedule element is transmitted, the PCP shall transmit it at least dot11MaxLostBeacons times before the PPS PCP enters the doze state.

The PCP shall check that the schedule of pseudo-static allocations transmitted in the last Extended Schedule element before the PCP entered PPS mode is valid during the PCP D-BIs. Thus, a STA participating in such a pseudo-static allocation assumes that the allocation is present during the following consecutive PCP D-BIs.

The PCP may enter and remain in the doze state for any portion of an SP if it is not a source or a destination of the SP. The PCP shall remain in the awake state for any portion of a truncatable or extendable SP (9.4.2.130). The CDMG PCP shall remain in the awake state for any portion of an extendable SP or a truncatable SP whose Truncation Type subfield is 0 (9.4.2.130). The availability of the PCP during a CBAP in the A-BI shall be announced by setting the PCP Active subfield within the Allocation Control field to 1 for a CBAP allocation made through the Extended Schedule element.

NOTE 4—A PCP that indicates availability during a CBAP that includes an awake window can exchange ATIM frames with non-AP and non-PCP STAs during the awake window and possibly enter the doze state for the remainder of the CBAP outside the awake window (see 11.2.7.4).

Figure 11-20 shows an example of the basic operation of a PCP in PPS mode when the PCP sleep interval equals one beacon interval (i.e., PCP is in doze state every other beacon interval) and the PCP sleep interval starts right after the first beacon interval. In this example, the first beacon interval and the second beacon interval have the same schedule, but the third beacon interval and the fourth beacon interval have different schedules. The first beacon interval is the A-BI in which the PPS PCP is in the awake state to serve non-PCP STAs. In the first beacon interval, the PCP transmits the Extended Schedule element for the current beacon interval with the pseudo-static subfield set to 1 for all allocations within the Extended Schedule element to indicate that the schedule of the first beacon interval also applies to the second beacon interval. In addition, the PCP transmits the DMG Wakeup Schedule element with the information of the start time and the length of the PCP sleep interval, and the STA Availability element to indicate the availability of the PCP for the CBAP of the A-BI. Following the CBAP of the first beacon interval, the PCP enters the doze state and sleeps for more than one beacon interval. The PCP remains in doze state through the remainder of the first beacon interval and through the entire second beacon interval, and transitions to awake state at the start of the third beacon interval in Figure 11-20 . Since in this example the schedule of the third beacon interval and the fourth beacon interval are different, the PCP transmits the Extended Schedule element containing the individual allocations for the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

third beacon interval and fourth beacon interval. The PCP enters the doze state after it completes all exchanges in the third beacon interval and wakes up at the start of the fifth beacon interval.

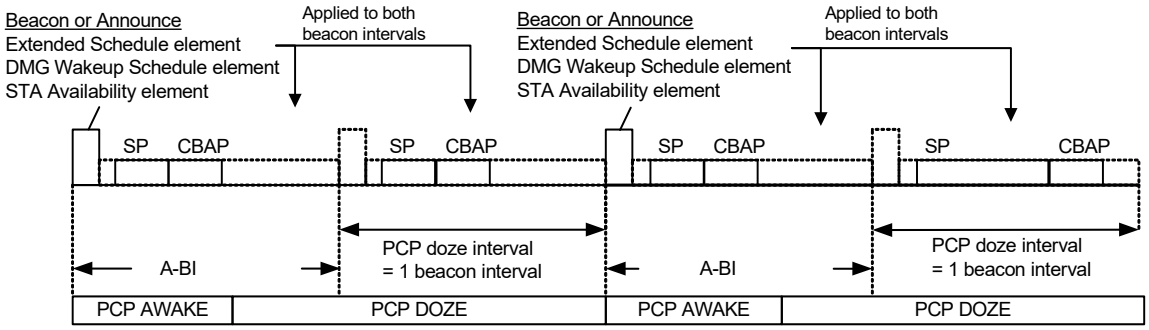

Figure 11-20—Example operation of PPS mode

11.2.7.4 ATIM frame usage for power management of non-AP STAs

An awake window is present within the first CBAP of a beacon interval that is scheduled through the Extended Schedule element and has the Source AID and Destination AID fields in that Extended Schedule element equal to the broadcast AID, or in a CBAP that is scheduled through the CBAP Only field in the DMG Parameters field (9.4.1.44) set to 1, for dot11MaxLostBeacons beacon intervals following the most recent transmission of the Awake Window element (9.4.2.136) by the AP or PCP with the Awake Window Duration field set to a nonzero value. If present in the first CBAP, the awake window starts from the beginning of a CBAP and has a duration that is defined by the value of the Awake Window Duration field in the Awake Window element or the CBAP duration, whichever is smaller.

If the value of the EDMG Awake Window Duration field within the transmitted Awake Window element is nonzero, an awake window is present within a CBAP allocation of a beacon interval if all of the following conditions are met:

— The CBAP allocation is scheduled in the beacon interval through the EDMG Extended Schedule element
— The CBAP allocation has the Source AID field equal to the broadcast AID

If all these conditions are met, the awake window is present in the CBAP allocation for dot11MaxLostBeacons beacon intervals following the most recent transmission of the Awake Window element by the AP or PCP. The awake window starts from the beginning of the CBAP and has a duration equal to the value of the EDMG Awake Window Duration field within the Awake Window element or the CBAP allocation duration, whichever is smaller.

NOTE 1—Transmission rules during the awake window are the same as the transmission rules for the CBAP that the awake window belongs to.

A non-AP and non-PCP STA delivers the Awake Window element to an AP or PCP as defined in 11.2.7.2.3. An AP or PCP delivers the Awake Window element to a non-AP and a non-PCP STA as defined 11.2.7.3.

During the awake window, a STA shall transmit only ATIM frames and, if the ATIM frame is individually addressed, Ack frames. A DMG STA in PS mode shall be in the awake state during each awake window that lies within each A-BI for that STA.

BUs that are to be transmitted to a STA that is in PS mode are first announced through ATIM frames during the awake window. A STA in PS mode that is awake during an awake window shall listen for these announcements to determine if it needs to change its power state. If during the awake window the STA does

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

not receive or transmit an ATIM frame with BSSID equal to the BSSID of the BSS of which the STA is a member, then it may enter the doze state at the end of the awake window. If a STA receives an ATIM frame during the awake window, it shall acknowledge the ATIM frame. Any two STAs that successfully complete an ATIM frame exchange with each other during the awake window become peer STAs.

A STA that is in PS mode and following a wakeup schedule and is in the awake state and receives an ATIM frame during the awake window shall be awake during allocations within the current beacon interval that have the Source AID equal to broadcast AID or have a Source AID that identifies a STA whose MAC address is equal to the TA field of the received ATIM frame, or during any DTI that is scheduled through the CBAP Only field in the DMG Parameters field (9.4.1.44) set to 1. If a STA transmits an ATIM frame during the awake window, it shall attempt to deliver its BUs during allocations within the current beacon interval that have a Destination AID equal to broadcast AID or have a Destination AID that identifies a STA whose MAC address is equal to the RA field of the transmitted ATIM frame, or during any DTI that is scheduled through the CBAP Only field in the DMG Parameters field (9.4.1.44) set to 1. A STA that receives from, or transmits to, a peer STA that is not an EDMG STA an ATIM frame during the awake window may enter the doze state when it has successfully transmitted to and received from all corresponding peer STAs for this beacon interval a QoS Data frame with the EOSP subfield set to 1; otherwise it shall stay active until the end of the current beacon interval. An EDMG STA that receives from, or transmits to, a peer EDMG STA an ATIM frame during an awake window may enter the doze state when it has successfully transmitted to and received from all corresponding peer STAs for this allocation a QoS Data frame with the EOSP subfield set to 1; otherwise, it shall remain active until the end of the allocation. ATIM frame transmissions and MSDU transmissions follow the rules defined in 11.2.8.

NOTE 2—A STA is in the doze state and receives an ATIM frame during an awake window can leave the doze state following the procedure in 11.2.7.2.2or 11.2.7.3.2.

Figure 11-21 illustrates an example of a DMG STA response to an ATIM frame. For illustration purposes the 5 beacon intervals shown in the figure are numbered from 0 to 4. The PCP is following a wakeup schedule, with 1 A-BI out of every 4 beacon intervals. The non-PCP STA A is also following a wakeup schedule, with 1 A-BI out of every 2 beacon intervals. In addition, STA A performs unscheduled power save during beacon interval 0, and also during beacon interval 2 to beacon interval 4. The PCP is required to remain awake during the following CBAP after receiving an ATIM frame in beacon interval 2. An ATIM frame received during beacon interval 4, however, serves as a traffic indication and PCP will transmit frames to STA A only after STA A is in the awake state.

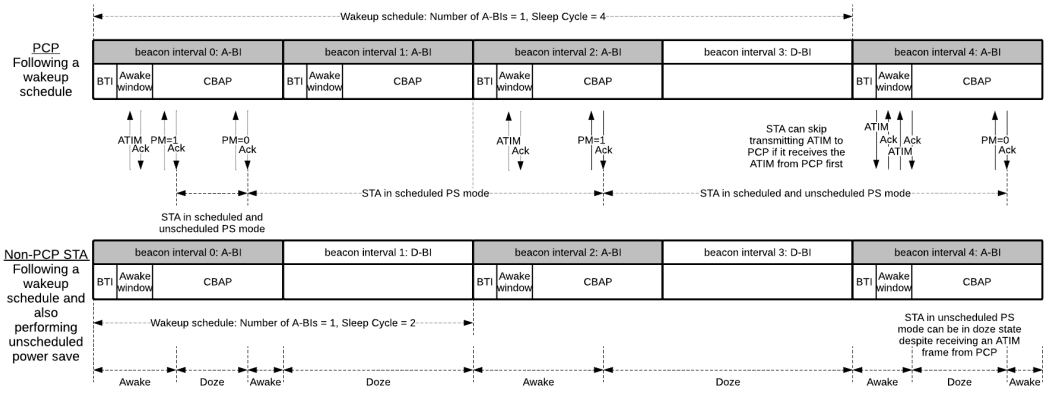

Figure 11-21—Example of ATIM frame response behavior in PS mode

The ATIM frame transmission result and EOSP notification result between a MAC address pair can be used for other MAC pairs that are members of the same MMSL cluster.

11.2.7.5 MU-MIMO power save

The MU-MIMO power save mechanism allows a non-AP and non-PCP EDMG STA in an infrastructure BSS or PBSS to go to PS mode during a TXOP where the STA is involved in an MU-MIMO transmission and acknowledgment procedures.

An EDMG STA that receives A-MPDUs within an EDMG MU PPDU may go to PS mode during the following two periods:

— First period: from the end of its individual A-MPDU within the EDMG MU PPDU to the time it needs to transmit its BA or RD response burst to the initiator (see 10.3.2.13 (MU acknowledgment procedure) and 10.29.5 (Reverse direction for EDMG DL MU-MIMO)).

— Second period: from the time of sending back the BA or RD response burst to the time indicated in Next PPDU Start Offset subfield in the Block Ack Schedule frame starting from the end of EDMG MU PPDU.

A STA that did not receive a Block Ack Schedule frame within a received MU PPDU shall remain awake in receive mode until it receives a BlockAckReq or Block Ack Schedule frame from the initiator or until the end of the TXOP, whichever comes first.

Once awake at the end of the second period, the EDMG STA shall stay in awake state until it receives the next EDMG MU PPDU from the initiator or until the end of the current TXOP, whichever comes first.

Figure 11-22 illustrates an example of MU-MIMO power save performed in an MU group with three EDMG STAs.

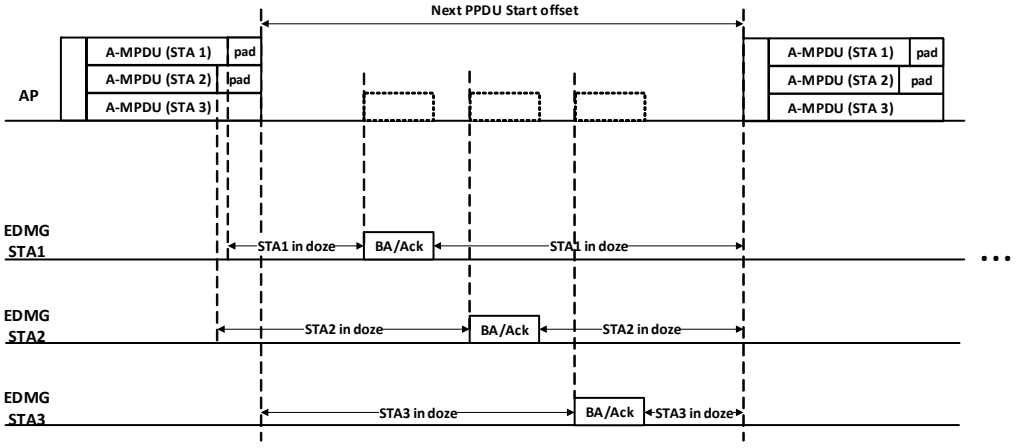

Figure 11-22—Example of MU-MIMO power save performed in MU group with three EDMG STAs

11.2.8 ATIM frame and frame transmission in IBSS, DMG infrastructure BSS, and PBSS

Power management in an IBSS is deprecated. If power management is in use within an IBSS, a STA shall buffer individually addressed BUs for STAs that are known to be in PS mode.

The following rules describe operation of the ATIM frame and frame transmission to STAs in PS mode in an IBSS, DMG infrastructure BSS and PBSS:

a) Following the reception or transmission of the Beacon frame in a non-DMG IBSS, during the ATIM window, the STA shall queue for transmission an individually addressed ATIM frame to each STA

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

for which it has one or more buffered individually addressed BUs and for which an ATIM frame is not already queued. Following the BTI or ATI in a DMG BSS, during the awake window, the STA shall queue for transmission an individually addressed ATIM frame to each STA for which it has one or more buffered individually addressed BUs and for which an ATIM frame is not already queued. If the STA has one or more buffered group addressed MSDUs or has one or more buffered group addressed MMPDUs, it shall queue for transmission an appropriately addressed group addressed ATIM frame if such an ATIM frame is not already queued.

b) In a non-DMG IBSS, a STA shall use the backoff procedure defined in 10.3.4.3 for transmission of the first ATIM frame following the Beacon frame. In a DMG BSS, a STA shall use the backoff procedure defined in 10.3.4.3 for transmission of the first ATIM frame following the BTI or ATI. All remaining ATIM frames shall be transmitted using the DCF (for non-QoS STAs) or the EDCAF (for QoS STAs).

c) ATIM frames shall be transmitted only during the ATIM window (for an IBSS STA) or awake window (for a non-IBSS DMG STA).

d) A non-DMG STA shall transmit no frame types other than RTS, CTS, Ack, Beacon, ATIM and (QoS) Null frames during the ATIM window.

e) Individually addressed ATIM frames shall be acknowledged. If no acknowledgment is received, the ATIM frame shall be retransmitted using either the DCF (for non-QoS STAs) or the EDCAF (for QoS STAs). Group addressed ATIM frames shall not be acknowledged.

f) If a STA is unable to transmit an ATIM frame during the ATIM window (for an IBSS STA) or awake window (for a non-IBSS DMG STA), for example due to contention with other STAs, the STA should retain the buffered BUs and either discard the ATIM frame or attempt to transmit the ATIM frame during the next the ATIM window (for an IBSS STA) or awake window (for a non-IBSS DMG STA).

g) Immediately following the ATIM window (for an IBSS STA) or awake window (for a non-IBSS DMG STA), a STA shall begin transmission of any buffered group addressed frames for which an ATIM frame was previously transmitted. Following the transmission of any group addressed frames, any BUs addressed to STAs for which an acknowledgment for a previously transmitted ATIM frame was received shall be transmitted. A STA shall use the backoff procedure defined in 10.3.4.3 for transmission of the first frame following the ATIM window (for an IBSS STA) or awake window (for a non-IBSS DMG STA). All remaining frames shall be transmitted using either the DCF (for non-QoS STAs) or the EDCAF (for QoS STAs).

h) If a buffered BU is transmitted using fragmentation and if the BU has been partially transmitted when the next Beacon frame is sent in a non-DMG IBSS or when the next beacon interval begins in a DMG BSS, the STA shall retain the buffered BU and announce the remaining fragments by transmitting an ATIM frame during the next the ATIM window (for an IBSS STA) or awake window (for a non-IBSS DMG STA).

i) If a STA is unable to transmit a buffered BU during the beacon interval in which it was announced, for example due to contention with other STAs, the STA shall retain the buffered BU and announce the BU again by transmitting an ATIM frame during the next the ATIM window (for an IBSS STA) or awake window (for a non-IBSS DMG STA).

j) Following the transmission of all buffered BUs, a STA may transmit BUs without announcement to STAs that are known to be in the awake state for the current beacon interval.

k) A STA may discard BUs buffered for later transmission to power saving STAs if the STA determines that the BU has been buffered for an excessive amount of time or if other conditions internal to the STA implementation make it desirable to discard buffered BUs (e.g., buffer starvation). A BU should not be discarded that has been buffered for less than dot11BeaconPeriod. The algorithm to manage this buffering is beyond the scope of this standard.

l) In order to indicate its intent to change power management modes, a STA shall transmit individually addressed or group addressed (QoS) Null frames within the ATIM window.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The STA shall not transition into or out of PS mode unless it has received acknowledgments from all recipients to which individually addressed (QoS) Null frames have been transmitted or after it has transmitted a sufficient number of group addressed (QoS) Null frames.

NOTE—The choice between individually addressed and group addressed transmissions, the peer STAs addressed for individually addressed transmissions, and the number of transmissions for group addressed transmissions are implementation choices outside the scope of the standard. A STA might base its choices on factors such as the number of peer STAs it is aware of in the IBSS, the expected traffic from each of these peer STAs, and the reliability of frame exchange sequences with these peer STAs.

11.2.9 Power management with general links

GLK STAs that have established general links (associations) have additional power management behaviors to support Data frames with a SYNRA and GLK GCR. These behaviors are in addition to the GLK STA behaviors listed in the previous subclauses.

NOTE 1—It is suggested that a STA using a general link that carries unknown traffic loads on behalf of other endpoints not use PS mode, due to the increased delay and jitter it would cause. However, GLK STAs that find PS mode useful might utilize PS mode while performing behaviors in this subclause.

Data frames with a SYNRA are queued for normal (nonbuffered) transmission to associated GLK STAs that are not in PS mode. A SYNRA shall not be used to address GLK STAs in PS mode.

NOTE 2—The net effect of the above is that any GLK non-AP STA in PS mode will, for all traffic for which the PS STA is a recipient, result in MPDUs that are buffered and, if there are multiple receivers, potentially duplicated. The IEEE 802.1Q bridge at the AP should use higher-layer facilities to filter traffic being sent to the STA so as to limit the amount of buffered traffic.

A GLK STA that has enabled GLK-GCR on its general link shall not enter PS mode. GLK STAs shall not use the FMS, TFS nor WNM-Sleep procedures applied to group addressed frames.

11.3 STA authentication and association

11.3.1 State variables

A STA (local) for which dot11OCBActivated is false keeps an enumerated state variable for each STA (remote) with which direct communication via the WM is needed. In this context, direct communication refers to the transmission of any Class 2 or Class 3 frame with an Address 1 field that matches the MAC address of the remote STA.

A STA for which dot11MeshActivated is true (i.e., a mesh STA) does not use procedures described in 11.3.5. Instead, a mesh STA uses a mesh peering management protocol (MPM) or a authenticated mesh peering exchange (AMPE) to manage states and state variables for each peer STA. See 14.4 and 14.6 for details.

A STA for which dot11OCBActivated is true does not use MAC sublayer authentication or association and does not keep this state variable.

For nonmesh STAs, this state variable expresses the relationship between the local STA and the remote STA. It takes on the following values:

— *State 1*: Initial start state for non-DMG STAs and for DMG STAs that perform IEEE 802.11 authentication. Unauthenticated and unassociated.

— *State 1a*: Authenticated for non-DMG STAs and for DMG STAs that have performed PASN authentication (12.13). Unassociated. Association is not possible from this state without non-PASN IEEE 802.11 authentication.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE—This state is used by STAs that wish to exchange robust management frames for example, perform secure ranging, but do not wish to exchange data frames.

— *State 2*: Initial start state for DMG STAs that do not perform IEEE 802.11 authentication. Authenticated (except DMG STAs that do not perform IEEE 802.11 authentication, which are unauthenticated) but unassociated.
— *State 3*: Authenticated (except DMG STAs that did not perform IEEE 802.11 authentication, which are unauthenticated) and associated (pending RSNA authentication). The IEEE 802.1X Controlled Port is blocked.
— *State 4*: Authenticated (except DMG STAs that did not perform IEEE 802.11 authentication, which are unauthenticated) and associated (RSNA established or not required). The IEEE 802.1X Controlled Port is unblocked, or not present.

The state variable is kept within the MLME (i.e., is written and read by the MLME). The SME may also read this variable using the MLME-GETAUTHASSOCSTATE.request primitive.

Mesh STAs manage the state variable as described in 14.4.2.

11.3.2 State transition diagram for nonmesh STAs

Figure 11-23 shows the state transition diagram for nonmesh STA states. Note that only events causing state changes are shown. The state of the sending STA given by Figure 11-23 is with respect to the intended receiving STA.

NOTE—A transition to State 1 might occur for other reasons such as no frames having been received from a STA for a period of time.

11.3.3 Frame filtering based on STA state

The current state existing between the transmitter and receiver STAs determines the IEEE 802.11 frame types that may be exchanged between that pair of STAs (see Clause 9). A unique state exists for each pair of transmitter and receiver STAs. The allowed frame types are grouped into classes and the classes correspond to the STA state. In State 1, only Class 1 frames are allowed. In State 2, only Class 1 or Class 2 frames are allowed. In State 3 and State 4, all frames are allowed (Classes 1, 2, and 3). In the definition of frame classes, the following terms are used:

— Within an infrastructure BSS: both the transmitting STA and the recipient STA participate in the same infrastructure BSS
— Within a PBSS: both the transmitting STA and the recipient STA participate in the same PBSS
— Within an IBSS: both the transmitting STA and the recipient STA participate in the same IBSS
— dot11RSNAActivated: reference to the setting of dot11RSNAActivated at the STA that needs to determine whether a transmission or reception is permitted.

NOTE—The phrase “within a BSS” comprises “within a PBSS,” “within an IBSS,” “within an MBSS,” or “within an infrastructure BSS.”

STA A participates in the same infrastructure BSS as STA B if at least one of the following conditions is met:

— STA A is associated with STA B, and either STA A or STA B is an AP.
— STA A receives a frame with the value of its TA field equal to the MAC address of STA B and with the value of its BSSID field equal to the BSSID of the BSS of which STA A is a member.
— STA A receives an Information Response frame from the AP with which it is associated containing an explicit indication that STA B is a member of the same BSS as STA A.

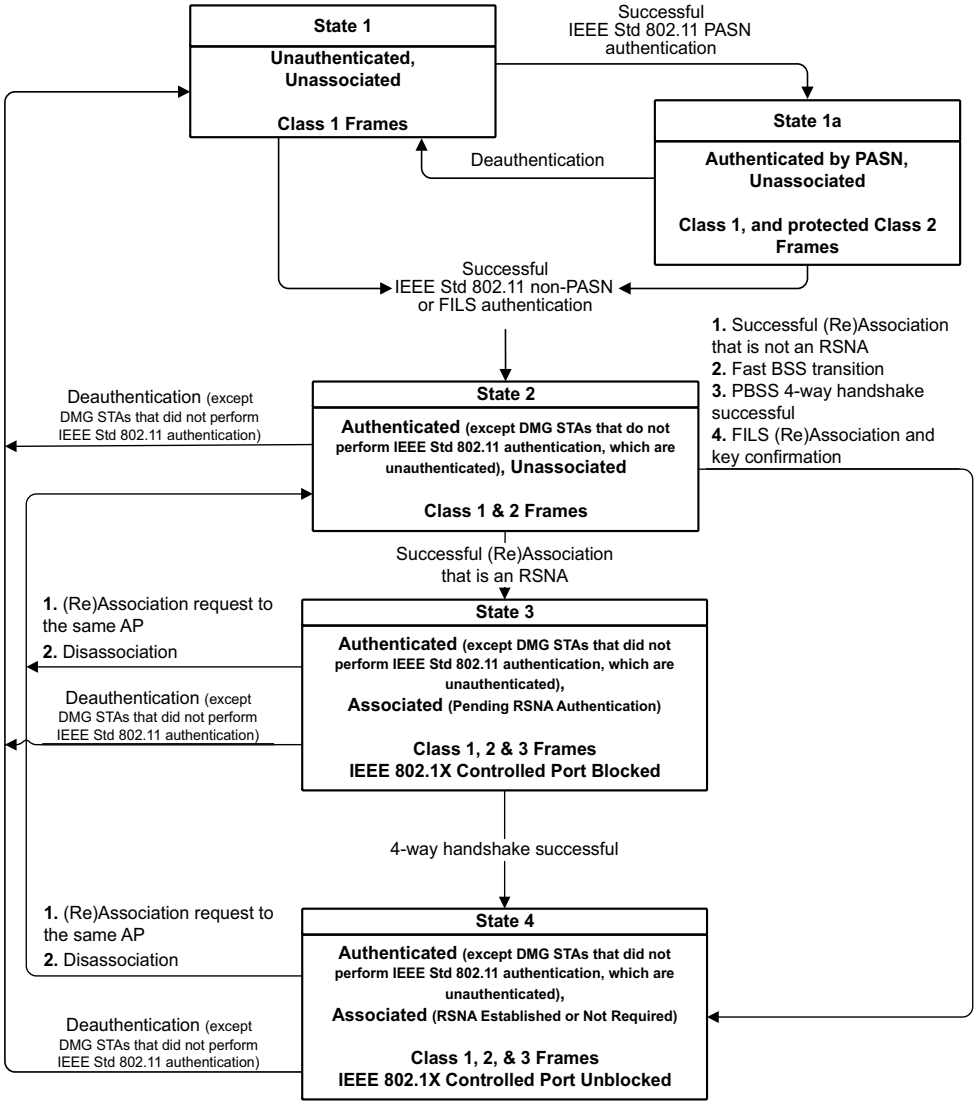

Figure 11-23—Relationship between state and services between a given pair of nonmesh STAs

STA A participates in the same PBSS as STA B if at least one of the following conditions is met:

— STA A is associated with STA B, and either STA A or STA B is a PCP.

— STA A receives a frame with the value of its TA field equal to the MAC address of STA B and with the value of its BSSID field equal to the BSSID of the PBSS that STA A has joined or started.

— STA A receives a frame, i.e., an Information Response frame, from its PCP containing an explicit indication that STA B is a member of the PBSS that STA A has joined.

STA A participates in the same IBSS as STA B if STA A receives a frame with the value of its TA field equal to the MAC address of STA B and with the value of its BSSID field equal to the BSSID of the IBSS that STA A has joined or started.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The frame classes are defined as follows:

a) Class 1 frames
   1) Control frames
      i) RTS
      ii) CTS
      iii) DMG Clear to send (DMG CTS)
      iv) Ack
      v) Grant
      vi) SSW
      vii) SSW-Feedback
      viii) SSW-Ack
      ix) Grant Ack
      x) CF-End
      xi) In an IBSS and in a PBSS when dot11RSNAActivated is false, Block Ack (BlockAck)
      xii) In an IBSS and in a PBSS when dot11RSNAActivated is false, Block Ack Request (BlockAckReq)
      xiii) In an HE BSS Basic Trigger frame and Multi-STA BlockAck frame
   2) Management frames
      i) Probe Request/Response
      ii) Beacon
      iii) Authentication
      iv) Deauthentication
      v) ATIM
      vi) Public Action
      vii) Self-protected Action
      viii) In an IBSS, all Action frames and all Action No Ack frames
      ix) Unprotected DMG Action frames
      x) In a PBSS when dot11RSNAActivated is false, all Action and Action No Ack frames except the following frames:
         1) ADDTS Request
         2) ADDTS Response
         3) DELTS
   3) Data frames
      i) Data frames between IBSS STAs
      ii) Data frames within a PBSS
      iii) EBCS Data frames
   4) Extension frames
      i) DMG Beacon
   5) WUR frames
      i) WUR Beacon
      ii) WUR Discovery

b) Class 1a frames
   In an infrastructure BSS when PTKSA from PASN authentication exists
   1) Protected Fine Timing frames (9.6.34)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

2) SA Query Request and SA Query Response frames sent to an individual address (11.13)

c) Class 2 frames
   1) Management frames
      i) Association Request/Response
      ii) Reassociation Request/Response
      iii) Disassociation

d) Class 3 frames
   1) Data frames
      i) Data frames between STAs in an infrastructure BSS or in an MBSS
   2) Management frames
      i) In an infrastructure BSS, an MBSS, or a PBSS, all Action and Action No Ack frames except those that are declared to be Class 1 or Class 2 frames
   3) Control frames
      i) PS-Poll
      ii) Poll
      iii) SPR
      iv) DMG DTS
      v) Block Ack (BlockAck), except those that are declared to be Class 1
      vi) Block Ack Request (BlockAckReq), except those that are declared to be Class 1 (above)
   4) WUR frames
      i) WUR Wake-up
      ii) WUR Short Wake-up

Class 2 and Class 3 frames are not allowed in an IBSS. If an IBSS STA receives a Class 2 or Class 3 frame, it shall discard the frame.

A STA shall not transmit Class 2 frames unless in State 2 or State 3 or State 4. In State 1a, a STA shall not transmit frames other than Class 1 and Class 1a frames.

A STA shall not transmit Class 3 frames unless in State 3 or State 4.

A multi-band capable device that uses OCT to move from State 2 to either State 3 or State 4 shall not transmit frames before the transmitting STA becomes over-the-WM enabled (see 11.31.5).

The use of the word “receive” in 11.3 refers to a frame that meets all of the filtering criteria specified in Clause 12 and Clause 10.

11.3.4 Authentication and deauthentication

11.3.4.1 General

This subclause describes the procedures used for IEEE 802.11 authentication and deauthentication. The states used in this description are defined in 11.3.1.

Successful authentication other than PASN authentication sets a STA’s state to State 2, if it was State 1 or State 1a. Successful PASN authentication sets the STA’s state to State 1a, if it was in State 1. PASN authentication is disallowed in states other than State 1. Unsuccessful authentication leaves the STA’s state unchanged.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Deauthentication notification sets the state for a STA to State 1. Deauthentication notification when in State 3 or 4 implies disassociation as well. A STA may deauthenticate a peer STA at any time, for any reason.

If STA A in an infrastructure BSS receives an unprotected Class 2 frame or a Class 3 frame from STA B when the state for STA B is State 1a, STA A shall discard the frame. If the frame has an individual address in the Address 1 field, the MLME of STA A should send a Deauthentication frame to STA B.

NOTE—STA A might choose not to send a frame if a denial-of-service attack is suspected.

If STA A in an infrastructure BSS receives any frame other than Class 1 and Class 1a frames (see 11.3.3) from STA B when in State 1a, STA A shall discard the frame.

Authentication is optional in an IBSS. In a non-DMG infrastructure BSS, authentication is required. In a DMG infrastructure BSS and PBSS, the Open System authentication algorithm is not used (see 12.3.3.1). APs and PCPs do not initiate authentication.

11.3.4.2 Authentication—originating STA

Upon receipt of an MLME-AUTHENTICATE.request primitive that is part of an on-channel tunneling (see 11.31.5), the originating STA shall follow the rules in 11.31.5 in addition to the authentication procedure described below.

Upon receipt of an MLME-AUTHENTICATE.request primitive, the originating STA shall authenticate with the indicated STA using the following procedure:

a) If the STA is in an IBSS, the SME shall delete any PTKSA, GTKSA, IGTKSA, WIGTKSA, WTKSA, and BIGTKSA (including temporal keys) held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 12.6.16).
b) The STA shall execute one of the following:
    1) For the Open System authentication algorithm, the authentication mechanism described in 12.3.3.2.
    2) For the fast BSS transition (FT) authentication algorithm in an ESS, the authentication mechanism described in 13.5, or, if resource requests are included, 13.6.
    3) For SAE authentication in an infrastructure BSS, IBSS, or MBSS, the authentication mechanism described in 12.4.
    4) For FILS authentication, the authentication mechanism described in 12.11. An AP or PCP may provide estimated association response latency to a non-AP and non-PCP STA using the Association Delay Info field in the Association Delay Info element (9.4.2.173). The value of the Association Delay Info field shall be larger than dot11HLPWaitTime.
    5) For PASN authentication, the authentication mechanism described in 12.13.
c) For any authentication protocol that is not PASN, if the authentication was successful within the AuthenticateFailureTimeout, the state for the indicated STA shall be set to State 2 if it was in State 1 or State 1a; the state shall remain unchanged if it was other than State 1 or State 1a.
d) For PASN authentication, if the authentication was successful within the AuthenticateFailureTimeout, the state for the indicated STA shall be set to State 1a if it was State 1; PASN authentication is disallowed in states other than State 1.
e) The MLME shall issue an MLME-AUTHENTICATE.confirm primitive to inform the SME of the result of the authentication.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.3.4.3 Authentication—destination STA

Upon receipt of an Authentication frame with authentication transaction sequence number equal to 1, the destination STA shall authenticate with the originating STA using the following procedure:

a) If Open System authentication algorithm is being used, the STA shall execute the procedure described in 12.3.3.2. These result in the generation of an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request.

b) If FT authentication is being used, the MLME shall issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request, including the FT Authentication Elements, and the SME shall execute the procedure as described in 13.5 or 13.6.

c) If SAE authentication is being used in an infrastructure BSS, IBSS, or MBSS, the MLME shall issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request, including the SAE authentication elements, and the SME shall execute the procedure as described in 12.4.

d) If FILS authentication is being used, the MLME shall issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request, and the SME shall execute the procedure described in 12.11.

e) If PASN authentication is being used, the MLME shall issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request, and the SME shall execute the procedure described in 12.13.

f) If the STA is in an IBSS and management frame protection was not negotiated when the PTKSA(s) were created, the SME shall delete any PTKSA, GTKSA, IGTKSA, WIGTKSA, WTKSA, and BIGTKSA (including temporal keys) held for communication with the originating STA by using the MLME-DELETEKEYS.request primitive (see 12.6.16).

g) Upon receipt of an MLME-AUTHENTICATE.response primitive, if the ResultCode is not SUCCESS, the MLME shall transmit an Authentication frame with the corresponding status code, as defined in 9.4.1.9, and the state for the originating STA shall be left unchanged. The Authentication frame is constructed using the appropriate procedure in 12.3.3.2, 13.5, 13.6, or 12.13.

h) Upon receipt of an MLME-AUTHENTICATE.response primitive, if the ResultCode is SUCCESS, the MLME shall transmit an Authentication frame that is constructed using the appropriate procedure in 12.3.3.2, 13.5 13.6 or 12.13, with a status code of SUCCESS. The state for the originating STA shall be set to State 2 if it was State 1 or State 1a when PASN authentication procedure was not used. The state for the originating STA shall be set to State 1a if it was in State 1 and PASN authentication procedure was used. PASN authentication shall be disallowed in states other than State 1.

NOTE—If management frame protection is negotiated, the SME does not change the state for the originating STA and does not delete any of the previously created SAs or temporal keys as a part of this authentication procedure.

If the STA is in an IBSS, if the SME decides to initiate an RSNA, and if the SME does not know the security policy of the peer, it may issue an individually addressed Probe Request frame to the peer by invoking an MLME-SCAN.request primitive to discover the peer's security policy.

When a non-AP and non-PCP STA receives an Authentication frame that includes an Association Delay Info element, it shall set dot11AssociationResponseTimeOut equal to or larger than the Association Delay Info field.

11.3.4.4 Deauthentication—originating STA

The originating STA shall deauthenticate with the indicated STA using the following procedure:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

a) The SME shall generate an MLME-DEAUTHENTICATE.request primitive containing the appropriate reason code for the STA deauthentication, as defined in Table 9-79 of 9.4.1.7.

b) On receipt of the MLME-DEAUTHENTICATE.request primitive, if the state for the indicated STA is State 1a, State 2, State 3, or State 4, the MLME shall generate a Deauthentication frame to be transmitted to the indicated STA.

NOTE—As the Deauthentication frame is a bufferable MMPDU, the transmission of this frame might be delayed by the operation of a power saving protocol. The AID and the PTKSA are maintained (when applicable) until the frame is acknowledged or attempts to transmit the frame are abandoned.

c) The state for the indicated STA shall be set to State 1.

d) Once the Deauthentication frame is acknowledged or attempts to transmit the frame are abandoned, the MLME shall issue an MLME-DEAUTHENTICATE.confirm primitive to inform the SME of the deauthentication.

e) The SME, upon receipt of an MLME-DEAUTHENTICATE.confirm primitive, shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 12.6.16) and by generating an MLME-SETPROTECTION.request(None) primitive.

f) If the STA is contained within an AP or PCP, its SME, upon receipt of an MLME-DEAUTHENTICATE.confirm primitive, shall release the AID assigned for the indicated STA, if the state for the indicated STA was State 3 or State 4.

g) If the STA is contained within an AP, its SME shall inform the DS of the disassociation, if the state for the indicated STA was State 3 or State 4.

h) If the STA is a mesh STA, its SME shall inform the mesh peering instance controller (see 14.4.4) of the deauthentication.

11.3.4.5 Deauthentication—destination STA

A DMG STA in State 2, State 3 or State 4 that receives a Deauthentication frame shall remain in the same state if it did not perform an IEEE 802.11 authentication exchange.

Otherwise, upon receipt of a Deauthentication frame from a STA for which the state is State 1a, State 2, State 3, or State 4, the destination STA shall deauthenticate with the originating STA using the following procedure:

a) If management frame protection was not negotiated when the PTKSA(s) were created, or if management frame protection was negotiated when the PTKSA(s) were created and the frame is not discarded per management frame protection processing, the MLME shall issue an MLME-DEAUTHENTICATE.indication primitive to inform the SME of the deauthentication, and set the state for the originating STA to State 1.

b) Upon receiving an MLME-DEAUTHENTICATE.indication primitive, the SME shall

   1) Delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA and TPKSA (including temporal keys) held for communication with the originating STA by using the MLME-DELETEKEYS.request primitive (see 12.6.16) and by generating an MLME-SETPROTECTION.request(None) primitive.

   2) If the STA is contained within an AP or PCP, release the AID assigned for the indicated STA.

   3) If the STA is contained within an AP, inform the DS of the disassociation, if the state for the originating STA was State 3 or State 4.

   4) If the STA is a mesh STA, inform the mesh peering instance controller (see 14.4.4) of the deauthentication.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.3.5 Association, reassociation, and disassociation

11.3.5.1 General

Subclause 11.3.5 describes the procedures used for IEEE 802.11 association, reassociation, and disassociation.

The states used in this description are defined in 11.3.1.

Successful association enables a STA to exchange Class 3 frames. Successful association sets the state for a non-FILS STA to State 3 or State 4. Successful association sets the state for FILS STAs to State 4. Association and reassociation are not allowed in State 1 and State 1a. In order to associate or reassociate, a STA in State 1 or State 1a shall perform an IEEE 802.11 non-PASN authentication or FILS authentication and transition to State 2.

Successful reassociation enables a STA to exchange Class 3 frames. Unsuccessful reassociation leaves the state for a STA state unchanged (with respect to the AP or PCP that was sent the Reassociation Request (which may be the current STA)). Successful reassociation sets the state for a non-FILS STA to State 3 or State 4 (with respect to the AP or PCP that was sent the Reassociation Request frame). Successful reassociation sets the state for a STA to State 2 (with respect to the current AP or PCP, if this is not the AP or PCP that was sent the Reassociation Request frame). Successful reassociation sets the state for a FILS STA to State 4 (with respect to the AP or PCP that was sent the Reassociation Request frame). Reassociation shall be performed only if the originating STA is already associated in the same ESS.

Disassociation notification when not in State 1 sets the state for a non-FILS STA to State 2. Disassociation notification when not in State 1 sets the state for a FILS STA to State 1. The STA shall become associated again prior to sending Class 3 frames. A STA may disassociate a peer STA at any time, for any reason. The state shall remain unchanged upon disassociation notification in State 1a.

If non-DMG STA A in an infrastructure BSS receives a Class 3 frame from STA B that is authenticated but not associated with STA A (i.e., the state for STA B is State 2 or State 1a), STA A shall discard the frame. If the frame has an individual address in the Address 1 field, the MLME of STA A should send a Disassociation frame to STA B.

NOTE—STA A might choose not to send a frame if a denial-of-service attack is suspected.

If DMG STA A in an infrastructure BSS receives a Class 3 frame from STA B that is not associated with STA A (i.e., the state for STA B is State 2 or State 1a), STA A shall discard the frame. If the frame has an individual address in the Address 1 field, the MLME of STA A shall send a Disassociation frame to STA B.

If an MM-SME coordinated STA receives an Association Response frame with a status code equal to SUCCESS and with the Single AID field within an MMS element equal to 1, then

— For each of its MAC entities advertised within the MMS element and for which dot11RSNAActivated is true, the state is set to State 3. Progress from State 3 to State 4 occurs independently in each such MAC entity.
— For each of its MAC entities advertised within the MMS element and for which dot11RSNAActivated is false, the state is set to State 4.

If the MM-SME coordinated STA in State 3 is assigned an AID for only the MAC entity identified by the RA field of the Association Response frame with status code equal to SUCCESS, the MM-SME may repeat the association procedure for any other MAC entity coordinated by the MM-SME.

Association is not applicable in an IBSS. In an infrastructure BSS, association is required to exchange Class 3 frames. In a PBSS, association is optional. APs and PCPs do not initiate association.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.3.5.2 Non-AP and non-PCP STA association initiation procedures

The SME shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the AP or PCP by using MLME-DELETEKEYS.request primitive (see 12.6.16) before invoking MLME-ASSOCIATE.request primitive.

If dot11InterworkingServiceActivated is true, the STA is associating with an AP but does not have credentials for the AP, and the STA is initiating an emergency services association procedure, the SME shall submit the MLME-ASSOCIATE.request primitive with EmergencyServices parameter set to true.

The MM-SME of a non-AP and non-PCP STA may include an MMS element in an MLME-ASSOCIATE.request primitive. The MM-SME shall include in the MMS element the MAC address associated with the MLME SAP instance to which the primitive is submitted.

Upon receipt of an MLME-ASSOCIATE.request primitive that is part of an on-channel tunneling (see 11.31.5), a non-AP and non-PCP STA shall follow the rules in 11.31.5 in addition to the association procedures described below.

Upon receipt of an MLME-ASSOCIATE.request primitive, a non-AP and non-PCP STA shall associate with an AP or PCP using the following procedure:

a) If the state for the AP or PCP is State 1 or State 1a, the MLME shall inform the SME of the failure of the association by issuing an MLME-ASSOCIATE.confirm primitive, and this procedure ends.
b) All the states, agreements and allocations listed in both numbered lists in 11.3.5.4 item c) are deleted or reset to initial values.
c) The MLME shall transmit an Association Request frame to the AP or PCP. The RSNE contained in the MLME-ASSOCIATE.request primitive shall be included in the Association Request frame. The RSNE shall specify exactly one pairwise cipher suite and exactly one AKM suite. If the MLME-ASSOCIATE.request primitive contained the EmergencyServices parameter equal to true, an Interworking element with the UESA field set to 1 shall be included in the Association Request frame.
d) If an Association Response frame is received with a status code of SUCCESS, a DMG STA shall write to each of the following MIB attributes the corresponding subfield of the DMG BSS Parameter Configuration field of the DMG Operation element received from the AP or PCP to which it requested association:
    1) dot11PSRequestSuspensionInterval from the PSRequestSuspensionInterval subfield
    2) dot11MinBHIDuration from the MinBHIDuration subfield
    3) dot11BroadcastSTAInfoDuration from the BroadcastSTAInfoDuration subfield
    4) dot11AssocRespConfirmTime from the AssocRespConfirmTime subfield
    5) dot11MinPPDuration from the MinPPDuration subfield
    6) dot11SPIdleTimeout from the SPIdleTimeout subfield
    7) dot11MaxLostBeacons from the MaxLostBeacons subfield
e) If an Association Response frame is received with a status code of SUCCESS, the state for the AP or PCP shall be set to State 4 or, if dot11RSNAActivated is true, State 3. The state for any other AP or PCP which is State 3 or State 4 prior to the association request shall be set to State 2, and the MLME shall issue an MLME-ASSOCIATE.confirm primitive to inform the SME of the successful completion of the association.
f) If an Association Response frame is received with a status code of SUCCESS at an MM-SME coordinated STA and the Single AID field within the MMS element is equal to 1, then

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— For each of its MAC entities advertised within the MMS element and for which dot11RSNAActivated is true, the state is set to State 3. Progress from State 3 to State 4 occurs independently in each such MAC entity.

— For each of its MAC entities advertised within the MMS element and for which dot11RSNAActivated is false, the state is set to State 4.

— For each of its MAC entities advertised within the MMS element the state for any other AP or PCP which is State 3 or State 4 prior to the association request shall be set to State 2.

g) If an Association Response frame is received with a status code other than SUCCESS or the association fails to complete within dot11AssociationResponseTimeout the state for the AP or PCP shall be set to State 2, and the MLME shall issue an MLME-ASSOCIATE.confirm primitive to inform the SME of the failure of the association. The status code returned in the Association Response frame indicates the cause of the failed association attempt. Any misconfiguration or parameter mismatch, e.g., data rates required as basic rates that the STA did not indicate as supported in the STA's Supported Rates and BSS Membership Selectors element, shall be corrected before the SME issues an MLME-ASSOCIATE.request primitive for the same AP or PCP. If the status code indicates the association failed because of a reason that is not related to configuration (e.g., the AP or PCP is unable to support additional associations) and the Association Response frame does not include a TIE with Timeout Interval Type equal to 3 the SME shall not issue an MLME-ASSOCIATE.request primitive for the same AP or PCP until a period of at least 2 s has elapsed. If the status code indicates the association failed and the Association Response frame contains a TIE with Timeout Interval Type equal to 3, the SME shall not issue an MLME-ASSOCIATE.request primitive for the same AP or PCP until the period specified in the TIE has elapsed.

h) If an MLME-ASSOCIATE.confirm primitive is received with a ResultCode of SUCCESS, and RSNA is required, and FILS authentication was not used, then the SME shall perform a 4-way handshake to establish an RSNA. As a part of a successful 4-way handshake, the SME shall enable protection by generating an MLME-SETPROTECTION.request(Rx_Tx) primitive. If an MLME-ASSOCIATE.confirm primitive is received with a ResultCode of SUCCESS, and FILS authentication was used, then the SME shall enable protection by generating an MLME-SETPROTECTION.request(Rx_Tx) primitive.

i) Upon receipt of the MLME-SETPROTECTION.request(Rx_Tx) primitive, the MLME shall set the state of the STA to State 4.

NOTE—Any MSDU fragments from the AP or PCP, and if management frame protection was negotiated for the existing association, any MMPDU fragments from the AP or PCP, are discarded at this point (see 12.6.12), since fragments are required to be encrypted with the same key (see 10.5).

11.3.5.3 AP or PCP association receipt procedures

Upon receipt of an Association Request frame from a STA the AP or PCP shall use the following procedure:

a) The MLME shall issue an MLME-ASSOCIATE.indication primitive to inform the SME of the association request. The SME shall issue an MLME-ASSOCIATE.response primitive addressed to the STA identified by the PeerSTAAddress parameter of the MLME-ASSOCIATE.indication primitive. If the association is not successful, the SME shall indicate a specific reason for the failure to associate in the ResultCode parameter. Upon receipt of the MLME-ASSOCIATE.response primitive, the MLME shall transmit an Association Response frame.

b) If the state for the STA is State 1 and the STA is a non-DMG STA, the SME shall refuse the association request by issuing an MLME-ASSOCIATE.response primitive with ResultCode NOT_AUTHENTICATED. If the state for the STA is State 1a and the STA is a non-DMG STA, the SME shall refuse the association request by issuing an MLME-ASSOCIATE.response primitive with ResultCode PASN_NOT_AUTHORIZED.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

c) AP with dot11InterworkingServiceActivated true only: If the MLME-ASSOCIATE.indication primitive has the EmergencyServices parameter set to true and the RSN parameter does not include an RSNE, the SME shall not reject the association request on the basis that dot11RSNAActivated is true, thereby granting access, using unprotected frames (see 9.2.4.1.9), to the network for emergency services purposes.

d) Otherwise, in an RSNA the SME shall check the values received in the RSN parameter to see whether the values received match the security policy. If they do not, the SME shall refuse the association by issuing an MLME-ASSOCIATE.response primitive with a ResultCode indicating the security policy mismatch.

e) Otherwise, if the state for the STA is State 4, the STA has a valid security association, the STA has negotiated management frame protection, the STA has not performed a successful SAE authentication after the current association was established, the STA did not include a valid Known STA Identification element (see 11.13), and there has been no earlier, timed out SA Query procedure with the STA (which would have allowed a new association process to be started, without an additional SA Query procedure):

   1) The SME shall refuse the association request by issuing an MLME-ASSOCIATE.response primitive with ResultCode REFUSED_TEMPORARILY and TimeoutInterval containing a TIE with the Timeout Interval Type field set to 3 (association comeback time). If the SME is in an ongoing SA Query with the STA, the Timeout Interval Value field shall be set to the remaining SA Query period, otherwise it shall be set to dot11AssociationSAQueryMaximumTimeout.
   2) The state for the STA shall be left unchanged.
   3) Following this, if the SME is not in an ongoing SA Query with the STA, the SME shall issue one MLME-SA-QUERY.request primitive addressed to the STA every dot11AssociationSAQueryRetryTimeout TUs until an MLME-SA-QUERY.confirm primitive for the STA is received or dot11AssociationSAQueryMaximumTimeout TUs from the beginning of the SA Query procedure have passed. The SME shall increment the TransactionIdentifier by 1 for each MLME-SA-QUERY.request primitive, rolling it over to 0 after the maximum allowed value is reached.
   4) If no MLME-SA-QUERY.confirm primitive for the STA is received within the dot11AssociationSAQueryMaximumTimeout period, the SME shall allow a subsequent association process with the STA to be started without starting an additional SA Query procedure, except that the SME may deny a subsequent association process with the STA if an MSDU was received from the STA within this period.

      NOTE 1—Reception of an MSDU implies reception of a valid protected frame, which obviates the need for the SA Query procedure.

f) The SME shall refuse an association request from a STA that does not support all of the rates in the BSSBasicRateSet parameter and all of the membership selectors in the BSSMembershipSelectorSet parameter in the MLME-START.request primitive.

g) The SME shall refuse an association request from an HT STA that does not support all of the MCSs in the Basic HT-MCS Set field of the HT Operation parameter in the MLME-START.request primitive.

h) The SME shall refuse an association request from a VHT STA that does not support all of the <VHT-MCS, NSS> tuples indicated by the Basic VHT-MCS And NSS Set field of the VHT Operation parameter in the MLME-START.request primitive.

i) The SME shall refuse an association request from an HE STA that does not support all of the <HE-MCS, NSS> tuples indicated by the Basic HE-MCS And NSS Set field of the HE Operation parameter in the MLME-START.request primitive.

j) An AP or PCP may refuse GLK association based on local policy and, if so, shall return the GLK_NOT_AUTHORIZED ResultCode.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 2—For example, there might be a list of authorized GLK peers or clients or a limit on the number of GLK peers or clients and the peer or client is not on that list or its acceptance would exceed the limit.

k) The SME shall generate an MLME-ASSOCIATE.response primitive with the PeerSTAAddress parameter set to the MAC address of the STA identified by the PeerSTAAddress parameter of the MLME-ASSOCIATE.indication primitive. If the ResultCode in the MLME-ASSOCIATE.response primitive is SUCCESS, the SME has an existing SA with the STA, and an SA Query procedure with that STA has failed to receive a valid response (i.e., has not received an MLME-SA-QUERY.confirm primitive within the dot11AssociationSAQueryMaximumTimeout period), the SME shall issue an MLME-DISASSOCIATE.request primitive addressed to the STA with ReasonCode INVALID_AUTHENTICATION.

NOTE 3—This MLME-DISASSOCIATE.request primitive generates a protected Disassociation frame. If the association request was genuine, the STA has deleted the PTKSA by this point and so the protected Disassociation frame is discarded. The purpose is to inform a STA that has for some reason failed to respond to an SA Query procedure triggered by a forged association request.

l) If the ResultCode in the MLME-ASSOCIATE.response primitive is SUCCESS, all the states, agreements and allocations pertaining to the associating STA and listed in both numbered lists in 11.3.5.4 item c) are deleted or reset to initial values.

m) If the ResultCode in the MLME-ASSOCIATE.response primitive is SUCCESS, the SME shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the STA by using the MLME-DELETEKEYS.request primitive (see 12.6.16 (RSNA security association termination)).

n) If the MLME-ASSOCIATE.indication primitive includes an MMS parameter, the AP or PCP shall generate the MLME-ASSOCIATE.response primitive directed to the MLME of the STA identified by the PeerSTAAddress parameter of the MLME-ASSOCIATE.request primitive and take the following additional action, as appropriate:

    1) If the Single AID field in the MMS parameter of the MLME-ASSOCIATE.indication primitive is equal to 1, the AP or PCP may allocate a single AID for all of the STAs included in the MMS element. If the AP or PCP allocates the same AID to each STA whose MAC address was included in the MMS element, it shall include the MMS element received from the MM-SME coordinated STA in the MLME-ASSOCIATE.response primitive.

    2) If the Single AID field is 0, the AP or PCP shall allocate a distinct AID for each STA specified in the MMS element.

NOTE 4—When the Single AID field is 0, a separate association request/response frame exchange is performed for each STA specified in the MMS element, and this assigns the multiple AIDs for the STAs.

o) If an Association Response frame with a status code of SUCCESS is acknowledged by the STA, the state for the STA shall be set to State 4 or, if dot11RSNAActivated is true, State 3.

p) If the ResultCode in the MLME-ASSOCIATE.response primitive is not SUCCESS and management frame protection was negotiated for the existing association the state for the STA shall be left unchanged. If the ResultCode is not SUCCESS and management frame protection was not negotiated for the existing association the state for the STA shall be set to State 3 if it was State 4.

NOTE 5—Any MSDU fragments from the STA, and if management frame protection was negotiated for the existing association, any MMPDU fragments from the STA, are discarded at this point (see 12.6.12), since fragments are required to be encrypted with the same key (see 10.5).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

q) If the ResultCode in the MLME-ASSOCIATE.response primitive is SUCCESS and RSNA establishment is required, and FILS authentication was not used, the SME shall attempt a 4-way handshake. Upon a successful completion of the 4-way handshake, the SME shall enable protection by issuing an MLME-SETPROTECTION.request(Rx_Tx) primitive. If FILS authentication was used, the SME shall enable protection by generating an MLME-SETPROTECTION.request(Rx_Tx) primitive. In either case, upon receipt of the MLME-SETPROTECTION.request(Rx_Tx) primitive, the MLME shall set the state for the STA to State 4.

r) AP only: The SME shall inform the DS of any changes in the state of the STA.

11.3.5.4 Non-AP and non-PCP STA reassociation initiation procedures

Except when the association is part of a fast BSS transition, the SME shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the AP or PCP by using the MLME-DELETEKEYS.request primitive (see 12.6.16) before invoking an MLME-REASSOCIATE.request primitive.

If dot11InterworkingServiceActivated is true and the STA was associated to the ESS for unsecured access to emergency services, the SME shall submit the MLME-REASSOCIATE.request primitive with EmergencyServices parameter set to true.

The MM-SME of a non-AP and non-PCP STA may include an MMS element in an MLME-REASSOCIATE.request primitive. The MM-SME shall include in the MMS element the MAC address associated with the MLME SAP instance to which the primitive is submitted.

Upon receipt of an MLME-REASSOCIATE.request primitive that is part of an on-channel tunneling (see 11.31.5), a non-AP and non-PCP STA shall follow the rules in 11.31.5 in addition to the reassociation procedures described below.

Upon receipt of an MLME-REASSOCIATE.request primitive, a non-AP and non-PCP STA shall reassociate with an AP or PCP using the following procedure:

a) If the STA is not associated in the same ESS or the state for the new AP or PCP is State 1 or State 1a, the MLME shall inform the SME of the failure of the reassociation by issuing an MLME-REASSOCIATE.confirm primitive, and this procedure ends.

b) The MLME shall transmit a Reassociation Request frame to the new AP or PCP. The RSNE contained in the MLME-ASSOCIATE.request primitive shall be included in the Reassociation Request frame. The RSNE shall specify exactly one pairwise cipher suite and exactly one AKM suite. If the MLME-REASSOCIATE.request primitive contained the EmergencyServices parameter equal to true, an Interworking element with the UESA field set to 1 shall be included in the Reassociation Request frame.

c) If a Reassociation Response frame is received with a status code of SUCCESS, the state variable for the new AP or PCP shall be set to State 4 or to State 3 if dot11RSNAActivated is true and the FT protocol is not used with respect to the new AP or PCP and, unless the old AP or PCP and new AP or PCP are the same, to State 2 with respect to the old AP or PCP, and the MLME shall issue an MLME-REASSOCIATE.confirm primitive to inform the SME of the successful completion of the reassociation.

   If the MLME-REASSOCIATION.request primitive has the new AP's or PCP's MAC address in the CurrentAPAddress parameter (reassociation to the same AP or PCP), the following states, agreements, and allocations shall be deleted or reset to initial values:

   1) All EDCAF state
   2) Any block ack agreements that are not GCR agreements
   3) Sequence number
   4) Duplicate detection caches

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

5) Anything queued for transmission
6) Fragmentation and reassembly buffers
7) Power management mode
8) WNM sleep mode
9) TDLS agreements
10) TPKSAs established with any peers
11) TSPECs
12) DMG TSPECs
13) GLK-GCR agreement
14) MSCS
15) SCS

If the reassociation is to the same AP (as described above), the following states, agreements, and allocations are not affected by the reassociation procedure:

1) Enablement/Deenablement
2) GDD enablement
3) MMSLs
4) GCR agreements that are not GLK-GCR agreements
5) DMS agreements
6) TFS agreements
7) FMS agreements
8) Triggered autonomous reporting agreements
9) FTM sessions
10) DMG SP and CBAP allocations
11) PTP TSPECs

In the case of reassociation to a different AP or PCP (the CurrentAPAddress parameter is not the new AP's or PCP's MAC address), all the states, agreements and allocations listed above are deleted or reset to initial values.

d) If a Reassociation Response frame is received with a status code of SUCCESS, a DMG STA shall write to each of the following MIB attributes the corresponding subfield of the DMG BSS Parameter Configuration field of the DMG Operation element received from the AP or PCP to which it requested reassociation:

1) dot11PSRequestSuspensionInterval from the PSRequestSuspensionInterval subfield
2) dot11MinBHIDuration from the MinBHIDuration subfield
3) dot11BroadcastSTAInfoDuration from the BroadcastSTAInfoDuration subfield
4) dot11AssocRespConfirmTime from the AssocRespConfirmTime subfield
5) dot11MinPPDuration from the MinPPDuration subfield
6) dot11SPIdleTimeout from the SPIdleTimeout subfield
7) dot11MaxLostBeacons from the MaxLostBeacons subfield

e) If an Association Response frame is received with a status code of SUCCESS at an MM-SME coordinated STA and the Single AID field within the MMS element is equal to 1, then

— For each of its MAC entities advertised within the MMS element and for which dot11RSNAActivated is true, the state is set to State 3. Progress from State 3 to State 4 occurs independently in each such MAC entity.
— For each of its MAC entities advertised within the MMS element and for which dot11RSNAActivated is false, the state is set to State 4.
— For each of its MAC entities advertised within the MMS element the state for any other AP or PCP which is State 3 or State 4 prior to the association request shall be set to State 2.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

f) If a Reassociation Response frame is received with a status code other than SUCCESS or the reassociation fails to complete within dot11AssociationResponseTimeout:

1) Except when the association is part of a fast BSS transition, the state for the AP or PCP shall be set to State 2 with respect to the new AP or PCP.

NOTE —This means the STA is disassociated in case of failure of reassociation to the same AP.

2) The MLME shall issue an MLME-REASSOCIATE.confirm primitive to inform the SME of the failure of the reassociation. The ResultCode returned in the MLME-REASSOCIATE.confirm primitive indicates the cause of the failed reassociation attempt. Any misconfiguration or parameter mismatch, e.g., data rates required as basic rates that the STA did not indicate as supported in the STA's Supported Rates and BSS Membership Selectors element, shall be corrected before the SME issues an MLME-REASSOCIATE.request primitive for the same AP or PCP. If the status code indicates the reassociation failed because of a reason that is not related to configuration (e.g., the AP or PCP is unable to support additional associations) and the Reassociation Response frame does not include a TIE with Timeout Interval Type equal to 3 the SME shall not issue an MLME-REASSOCIATE.request primitive for the same AP or PCP until a period of at least 2 s has elapsed. If the status code indicates the reassociation failed and the Reassociation Response frame contains a TIE with Timeout Interval Type equal to 3, the SME shall not issue an MLME-REASSOCIATE.request primitive for the same AP or PCP until the period specified in the TIE has elapsed.

g) If an MLME-REASSOCIATE.confirm primitive is received with a ResultCode of SUCCESS, and RSNA is required, and FILS authentication was not used, and the STA is in State 3, then the SME shall perform a 4-way handshake to establish an RSNA. As a part of a successful 4-way handshake, the SME shall enable protection by generating an MLME-SETPROTECTION.request(Rx_Tx) primitive. If an MLME-REASSOCIATE.confirm primitive is received with a ResultCode of SUCCESS, and FILS authentication was used, and the STA is in State 3, then the SME shall enable protection by generating an MLME-SETPROTECTION.request(Rx_Tx) primitive.

h) Upon receipt of the MLME-SETPROTECTION.request(Rx_Tx) primitive, the MLME shall set the state of the STA to State 4.

NOTE—Per item 6) in the first list under c) any MSDU fragments in the reassembly buffers, and if management frame protection was negotiated for the existing association, any MMPDU fragments, have been discarded. This is important since fragments are required to be encrypted with the same key (see 10.5).

11.3.5.5 AP or PCP reassociation receipt procedures

Upon receipt of a Reassociation Request frame from a STA the AP or PCP shall use the following procedure:

a) The MLME shall issue an MLME-REASSOCIATE.indication primitive to inform the SME of the reassociation request. The SME shall issue an MLME-REASSOCIATE.response primitive addressed to the STA identified by the PeerSTAAddress parameter of the MLME-REASSOCIATE.indication primitive. If the reassociation is not successful, the SME shall indicate a specific reason for the failure to reassociate in the ResultCode parameter. Upon receipt of the MLME-REASSOCIATE.response primitive, the MLME shall transmit a Reassociation Response frame.

b) If the state for the STA is State 1 or State 1a and the STA is a non-DMG STA, the SME shall refuse the reassociation request by issuing an MLME REASSOCIATE.response primitive with ResultCode NOT_AUTHENTICATED. If the state for the STA is State 1a and the STA is a non-DMG STA, the SME shall refuse the reassociation request by issuing an MLME REASSOCIATE.response primitive with ResultCode PASN_NOT_AUTHORIZED.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

c) AP with dot11InterworkingServiceActivated true only: If the MLME-REASSOCIATE.indication primitive has the EmergencyServices parameter set to true and the RSN parameter does not include an RSNE, the SME shall not reject the reassociation request on the basis that dot11RSNAActivated is true thereby granting access, using unprotected frames (see 9.2.4.1.9), to the network for emergency services purposes.

d) Otherwise, in an RSNA the SME shall check the values received in the RSN parameter to see whether the values received match the security policy. If they do not, SME shall refuse the reassociation by issuing an MLME-REASSOCIATE.response primitive with a ResultCode indicating the security policy mismatch.

e) Otherwise, if the state for the STA is State 4, the STA has a valid security association, the STA has negotiated management frame protection, the reassociation is not a part of a fast BSS transition, the STA has not performed a successful SAE authentication after the current association was established, the STA did not include a valid Known STA Identification element (see 11.13), and there has been no earlier, timed out SA Query procedure with the STA (which would have allowed a new reassociation process to be started, without an additional SA Query procedure):

   1) The SME shall refuse the reassociation request by issuing an MLME-REASSOCIATE.response primitive with ResultCode REFUSED_TEMPORARILY and TimeoutInterval containing a TIE with the Timeout Interval Type field set to 3 (association comeback time). If the SME is in an ongoing SA Query with the STA, the Timeout Interval Value field shall be set to the remaining SA Query period, otherwise it shall be set to dot11AssociationSAQueryMaximumTimeout.
   2) The state for the STA shall be left unchanged.
   3) Following this, if the SME is not in an ongoing SA Query with the STA, the SME shall issue one MLME-SA-QUERY.request primitive addressed to the STA every dot11AssociationSAQueryRetryTimeout TUs until an MLME-SA-QUERY.confirm primitive for the STA is received or dot11AssociationSAQueryMaximumTimeout TUs from the beginning of the SA Query procedure have passed. The SME shall increment the TransactionIdentifier by 1 for each MLME-SA-QUERY.request primitive, rolling it over to 0 after the maximum allowed value is reached.
   4) If no MLME-SA-QUERY.confirm primitive for the STA is received within the dot11AssociationSAQueryMaximumTimeout period, the SME shall allow a subsequent reassociation process to be started without starting an additional SA Query procedure, except that the SME may deny a subsequent reassociation process with the STA if an MSDU was received from the STA within this period.

      NOTE 1—Reception of an MSDU implies reception of a valid protected frame, which obviates the need for the SA Query procedure.

f) The SME shall refuse a reassociation request from a STA that does not support all the rates in the BSSBasicRateSet parameter and all of the membership selectors in the BSSMembershipSelectorSet parameter in the MLME-START.request primitive.

g) The SME shall refuse a reassociation request from an HT STA that does not support all of the MCSs in the Basic HT-MCS Set field of the HT Operation parameter in the MLME-START.request primitive.

h) The SME shall refuse a reassociation request from a VHT STA that does not support all of the <VHT-MCS, NSS> tuples indicated by the Basic VHT-MCS And NSS Set field of the VHT Operation parameter in the MLME-START.request primitive.

i) The SME shall refuse a reassociation request from an HE STA that does not support all of the <HE-MCS, NSS> tuples indicated by the Basic HE-MCS And NSS Set field of the HE Operation parameter in the MLME-START.request primitive.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

j) If the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS, the SME has an existing SA with the STA, and an SA Query procedure with that STA has failed to receive a valid response (i.e., has not received an MLME-SA-QUERY.confirm primitive within the dot11AssociationSAQueryMaximumTimeout period), the SME shall issue an MLME-DISASSOCIATE.request primitive addressed to the STA with ReasonCode INVALID_AUTHENTICATION.

NOTE 2—This MLME-DISASSOCIATE.request primitive generates a protected Disassociation frame. If the reassociation request was genuine, the STA has deleted the PTKSA by this point and so the protected Disassociation frame is discarded. The purpose is to inform a STA that has for some reason failed to respond to an SA Query procedure triggered by a forged reassociation request.

k) If management frame protection was not negotiated for the existing association, or the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS and the reassociation is not part of a fast BSS transition, the SME shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the STA by using the MLME-DELETEKEYS.request primitive (see 12.6.16 (RSNA security association termination)).

l) If the MLME-REASSOCIATE.indication primitive includes an MMS parameter, the AP or PCP shall take the following additional action, as appropriate:

1) If the Single AID field in the MMS parameter of the MLME-REASSOCIATE.indication primitive is equal to 1, the AP or PCP may allocate a single AID for all of the STAs included in the MMS element. If the AP or PCP allocates the same AID to all STAs whose MAC address was included in the MMS element, it shall include the MMS element received from the MM-SME coordinated STA in the MLME-REASSOCIATE.response primitive.

2) If the Single AID field is 0, the AP or PCP shall allocate a distinct AID for each STA specified in the MMS element.

NOTE 3—When the Single AID field is 0, a separate reassociation request/response frame exchange is performed for each STA specified in the MMS element, and this assigns the multiple AIDs for the STAs.

m) If a Reassociation Response frame with a status code of SUCCESS is acknowledged by the STA, the state for the STA shall be set to State 4, or to State 3 if dot11RSNAActivated is true and the reassociation is not part of a fast BSS transition.

n) If the ResultCode in the MLME-REASSOCIATE.response primitive is not SUCCESS and management frame protection was negotiated for the existing association the state for the STA shall be left unchanged. If the ResultCode is not SUCCESS, management frame protection was not negotiated for the existing association, and the reassociation is part of a fast BSS transition, the state for the STA shall be left unchanged. If the ResultCode is not SUCCESS, management frame protection was not negotiated for the existing association, the reassociation is not part of a fast BSS transition, and the state for the STA was State 3 or State 4, the state for the STA shall be set to State 2 if the reassociation is for the same AP, or to State 3 otherwise.

o) If the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS, RSNA establishment is required, and the reassociation is not part of a fast BSS transition, and FILS is not in use, the SME shall attempt a 4-way handshake. Upon a successful completion of a 4-way handshake, the SME shall enable protection by issuing an MLME-SETPROTECTION.request(Rx_Tx) primitive. If FILS authentication was used, the SME shall enable protection by generating an MLME-SETPROTECTION.request(Rx_Tx) primitive. In either case, upon receipt of the MLME-SETPROTECTION.request(Rx_Tx) primitive, the MLME shall set the state for the STA to State 4.

p) AP only: The SME shall inform the DS of any changes in the state of the STA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

q) If the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS and the CurrentAPAddress parameter in the MLME-REASSOCIATION.indication primitive is this AP's or PCP's MAC address (reassociation to the same AP or PCP), the AP or PCP shall match the non-AP STA's treatment of the listed agreements and allocations as described in 11.3.5.4 item c). The AP or PCP deletes or resets to initial values those items that the non-AP STA is required in 11.3.5.4 item c) to delete or reset to initial values, and the AP or PCP does not modify the states, agreements and allocations that are listed as not affected by the reassociation procedure.

r) If the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS and the CurrentAPAddress parameter in the MLME-REASSOCIATION.indication primitive is not this AP's or PCP's MAC address (reassociation to a different AP or PCP), all the states, agreements and allocations pertaining to the associating STA and listed in both numbered lists in 11.3.5.4 item c) are deleted or reset to initial values.

NOTE 4—Per 11.3.5.4 item 6) in the first list under c) any MSDU fragments in the reassembly buffers, and if management frame protection was negotiated for the existing association, any MMPDU fragments, have been discarded. This is important since fragments are required to be encrypted with the same key (see 10.5).

11.3.5.6 Non-AP and non-PCP STA disassociation initiation procedures

The SME shall issue an MLME-DISASSOCIATE.request primitive that includes an appropriate Reason Code as defined in Table 9-79 of 9.4.1.7.

Upon receipt of an MLME-DISASSOCIATE.request primitive, a non-AP and non-PCP STA's MLME shall disassociate from an AP or PCP using the following procedure:

a) If the state for the AP or PCP is State 3 or State 4, the MLME shall transmit a Disassociation frame to the AP or PCP.

b) The state for the AP or PCP shall be set to State 2 if it was not State 1 or State 1a. In the case of an MM-SME coordinated STA, the MLME shall perform this for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.

c) The MLME shall issue an MLME-DISASSOCIATE.confirm primitive to inform the SME of the successful completion of the disassociation.

d) Upon receiving an MLME-DISASSOCIATE.confirm primitive, the SME shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the AP or PCP by using the MLME-DELETEKEYS.request primitive (see 12.6.16) and by invoking an MLME-SETPROTECTION.request(None) primitive. In the case of an MM-SME coordinated STA, the MLME shall perform this for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.

11.3.5.7 Non-AP and non-PCP STA disassociation receipt procedure

Upon receipt of a Disassociation frame from an AP or PCP for which the state is State 3 or State 4, if management frame protection was not negotiated when the PTKSA(s) were created, or if management frame protection was negotiated when the PTKSA(s) were created and the frame is not discarded per management frame protection processing, a non-AP and non-PCP STA shall disassociate from the AP or PCP using the following procedure:

a) The state for the AP or PCP shall be set to State 2.

b) The MLME shall issue an MLME-DISASSOCIATE.indication primitive to inform the SME of the disassociation.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

c) Upon receiving the MLME-DISASSOCIATE.indication primitive, the SME shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the AP or PCP by using the MLME-DELETEKEYS.request primitive (see 12.6.16) and by invoking an MLME-SETPROTECTION.request(None) primitive. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.

d) If the reason code indicates a configuration or parameter mismatch as the cause of the disassociation, the SME shall not attempt to associate or reassociate with the AP or PCP until the configuration or parameter mismatch has been corrected.

e) If the reason code indicates the STA was disassociated for a reason other than configuration or parameter mismatch, the SME shall not attempt to associate or reassociate with the AP or PCP until a period of 2 s has elapsed.

11.3.5.8 AP or PCP disassociation initiation procedure

The SME shall issue an MLME-DISASSOCIATE.request primitive that includes an appropriate Reason Code as defined Table 9-79 of 9.4.1.7.

Upon receipt of an MLME-DISASSOCIATE.request primitive, an AP or PCP shall disassociate a STA using the following procedure:

a) If the state for the STA is State 3 or State 4, the AP or PCP shall generate a Disassociation frame to be transmitted to the indicated STA.

NOTE—As the Disassociation frame is a bufferable MMPDU, the transmission of this frame might be delayed by the operation of a power saving protocol. The AID and the PTKSA are maintained (when applicable) until the frame is acknowledged or attempts to transmit the frame are abandoned.

b) The state for the STA shall be set to State 2, if it was not State 1 or State 1a. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.

c) Once the Disassociation frame is acknowledged or attempts to transmit the frame are abandoned, the MLME shall issue an MLME-DISASSOCIATE.confirm primitive to inform the SME of the disassociation.

d) Upon receiving an MLME-DISASSOCIATE.confirm primitive, the SME shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the STA by using the MLME-DELETEKEYS.request primitive (see 12.6.16) and by invoking an MLME-SETPROTECTION.request(None) primitive. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.

e) Upon receiving an MLME-DISASSOCIATE.confirm primitive, the SME shall release the AID assigned for the indicated STA, if the state for the indicated STA was State 3 or State 4.

f) AP only: The SME shall inform the DS of the disassociation.

11.3.5.9 AP or PCP disassociation receipt procedure

Upon receipt of a Disassociation frame from a STA for which the state is State 3 or State 4, if management frame protection was not negotiated when the PTKSA(s) were created, or if management frame protection was negotiated when the PTKSA(s) were created and the frame is not discarded per management frame protection processing, the AP or PCP shall disassociate the STA using the following procedure:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

a) The state for the STA shall be set to State 2. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.
b) The MLME shall issue an MLME-DISASSOCIATE.indication primitive to inform the SME of the disassociation.
c) Upon receiving an MLME-DISASSOCIATE.indication primitive the SME shall delete any PTKSA, GTKSA, IGTKSA, BIGTKSA, WIGTKSA, WTKSA, and TPKSA (including temporal keys) held for communication with the STA by using the MLME-DELETEKEYS.request primitive (see 12.6.16) and by invoking an MLME-SETPROTECTION.request(None) primitive. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.
d) AP only: The SME shall inform the DS of the disassociation.
e) The SME shall release the AID assigned for the indicated STA.

11.3.5.10 PBSS procedures for nonassociated STAs

In a PBSS, there are four types of relationships between a PCP and the members of a PBSS:

— Nonassociated, pre-RSNA (when dot11RSNAActivated is false)
— Associated, pre-RSNA (when dot11RSNAActivated is false)
— Associated, RSNA (when dot11RSNAActivated is true)
— Nonassociated, RSNA (when dot11RSNAActivated is true)

The following rules apply in the last case:

a) In a PBSS, when a STA is in State 2 and dot11RSNAActivated is true, successful RSNA establishment changes the STA to State 4. Unsuccessful RSNA establishment leaves the state unchanged.
b) In a PBSS, when a STA is in State 4, the STA's receipt of a disassociation notification changes the state to State 2.

11.3.5.11 Service characteristic indication during association

A sensor service is the service that a sensor STA is capable of provisioning that is usually delivered using small payload Data frames. Non-sensor services include offloading and critical services. Different service characteristics may have different requirements on QoS, frame length, duty cycle, etc. An AP can optimize the system operating parameters with the knowledge of the service characteristic of each associated STA or place a high priority on association/reassociation for a STA that provides critical services such as health care, home, industrial, alarm monitoring or emergency service.

A non-AP STA may indicate to the AP its service characteristic information during association by including the Service Characteristic field in the AID Request element in the (Re)Association Request frame. The AP may assign a particular AID to the STA taking into account the received service characteristic information from the STA.

11.3.6 Additional mechanisms for an AP colocated with a mesh STA

If a STA to AP mapping is added to the DS with the STA being a non-AP STA in an infrastructure BSS and the AP being an access point that interconnects through a DS with a mesh gate (that is, AP and mesh gate are colocated; see Figure 4-10), this mesh gate shall verify that the MAC address of the STA does not belong to a mesh STA in the MBSS. See 4.5.3.3 and Clause 7 for association and STA to AP mapping in the DS. If the mesh gate determines that the authenticated STA has a MAC address that is a MAC address of a mesh STA in

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the MBSS, then the colocated access point shall deauthenticate the STA with Reason Code UNSPECIFIED_REASON or MACADDRESS-ALREADY-EXISTS-IN-MBSS.

The mechanism for verifying the MAC address of the authenticated STA depends on the active path selection protocol and might be vendor specific. See 14.11.13 when HWMP is the active path selection protocol.

11.3.7 Communicating PBSS information

Following the association or security association of a STA with a PCP, the PCP shall send an unsolicited Information Response frame (9.6.19.5 to all STAs associated with the PCP. The PCP shall send a broadcast Information Response frame and/or shall send individually addressed Information Response frames to each STA associated with the PCP. The PCP shall set the Subject Address field of the Information Response frame to the broadcast address and shall include in the Information Response frame the DMG Capabilities element for the PCP and each STA associated with the PCP. This process is referred to as *PBSS information distribution*.

The PCP shall perform a PBSS information distribution at least once every dot11BroadcastSTAInfoDuration beacon intervals.

11.3.8 Neighbor report information upon rejection with suggested BSS transition

An AP may provide neighbor report information to a STA that requests authentication or association by responding with an Authentication or (Re)Association Response frame that has the Status Code field set to REJECTED_WITH_SUGGESTED_BSS_TRANSITION and that includes one or more Neighbor Report elements.

An HE STA that has received from an HE AP an Authentication or (Re)Association Response frame that has the Status Code field set to REJECTED_WITH_SUGGESTED_BSS_TRANSITION and that includes one or more Neighbor Report elements for BSSs that are part of the ESS of the HE AP shall, if it re-attempts to associate with the ESS, select an AP from (one of) the Neighbor Report element(s).

11.3.9 Authentication control

11.3.9.1 General

In infrastructure mode, an S1G AP can use the Authentication Control element to alleviate WM contention when a large number of STAs are trying to or are expected to send Authentication-Request frames to the AP at about the same time.

11.3.9.2 Centralized authentication control

When dot11S1GCentralizedAuthenticationControlActivated is true, an S1G STA shall set the Centralized Authentication Control subfield to 1 in the S1G Capabilities Information field of the S1G Capabilities element. Otherwise, the STA shall set it to 0. A STA that transmits the Centralized Authentication Control subfield of the S1G Capabilities Information field set to 0 is not constrained by the requirements specified in this subclause.

A centralized authentication controller access point (CAC AP) shall set the Control subfield to 0 in the Authentication Control element in all transmitted Beacons and Probe Responses frames. A non-CAC AP shall not include an Authentication Control element with the Control field equal to 0 in a Beacon or Probe Response frame.

A CAC AP may include an Authentication Control element with the Control subfield equal to 0 and the Deferral subfield equal to 0 in a Beacon or a Probe Response frame to attempt to limit the number of STAs that

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

can transmit an Authentication-Request frame to it. The AP may transmit a different value in the Authentication Control Threshold subfield in the Authentication Control element included in each of Beacon and Probe Response frames that it transmits.

A CAC AP may include, within an individually addressed Probe Response frame that is transmitted in response to a Probe Request frame from a STA, an Authentication Control element that has the Control subfield equal to 0, the Deferral subfield equal to 1 and the Authentication Control Threshold subfield equal to a deferred channel access time. During the deferred channel access time that begins immediately following the reception of the Probe Response, a centralized authentication controlled station (CAC STA) shall not transmit an Authentication-Request frame to the AP that transmitted the Probe Response frame.

A non-CAC STA is not constrained by the Authentication Control rules specified in this subclause when it transmits an Authentication-Request frame to the AP. A CAC STA sets the MAC variable AuthenticationRequestTransmission to true when it is initialized.

A CAC STA shall generate a random number *v* when it is initialized. The generated random number *v* shall be uniformly distributed between 0 and 1022. The STA may generate a new random value for *v* after receiving an Authentication-Response frame from an AP.

A CAC STA shall compare *v* with the Authentication Control Threshold subfield value in the most recently received Authentication Control element from the AP to which it intends to send an Authentication-Request frame if the Control and the Deferral subfields are equal to 0. If *v* is less than the Authentication Control Threshold subfield, the STA may transmit an Authentication-Request frame to the AP and shall set the MAC variable AuthenticationRequestTransmission to true. Otherwise, the STA shall set the MAC variable AuthenticationRequestTransmission to false and the STA shall not transmit an Authentication-Request frame to the AP. A CAC STA shall update its MIB values of the CAC parameters based on the values received in the Authentication Control element.

A CAC STA shall set the MAC variable AuthenticationRequestTransmission to false and shall defer the transmission of an Authentication-Request frame to an AP from which it has received an individually addressed probe response if the Probe Response frame contains an Authentication Control element with the Control subfield equal to 0 and the Deferral subfield equal to 1. The deferral begins at the end of the reception of the Probe Response frame and extends for a period of time equal to the value contained in the Authentication Control Threshold subfield value in the Probe Response frame. At the end of the deferral time period, the STA shall set the MAC variable AuthenticationRequestTransmission to true and may transmit an Authentication-Request frame to the AP.

A CAC STA shall set the MAC variable AuthenticationRequestTransmission to true when it receives a Beacon or Probe Response frame that does not include an Authentication Control element from the AP that it intends to join.

An S1G AP shall not set the Deferral subfield in the Authentication Control element of the Beacon frames or the broadcast Probe Response frames to 1.

An S1G STA does not follow the Authentication Control rules defined in this subclause if it receives a Beacon or Probe Response frame that includes an Authentication Control element from the AP that it does not intend to join, or is not intended to the STA.

11.3.9.3 Distributed authentication control

When dot11S1GDistributedAuthenticationControlActivated is true, an S1G AP shall set the Distributed Authentication Control subfield to 1 in the S1G Capabilities Information field of the S1G Capabilities element. Otherwise, the subfield is set to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When an S1G STA receives an S1G Capabilities element with the Distributed Authentication Control field equal to 1, the STA shall determine when it is permitted to access the medium to transmit an Authentication-Request frame to the AP from which it received the S1G Capabilities element based on the following procedure:

a) The STA maintains the following distributed authentication control (DAC) parameters:
   1) Authentication control slot duration (T_{ac}) in TUs. The default value is 10 TUs.
   2) Minimum transmission interval (TI_{min}) in units of a beacon interval. The default value is 8 beacon intervals.
   3) Maximum transmission interval (TI_{max}) in units of a beacon interval. The default value is 256 beacon intervals.
b) The STA maintains a transmission interval (TI) in units of a beacon interval.
c) The TI is initialized to TI_{min}.
d) The STA chooses a random number *m* from [0, TI].
e) The STA chooses a random number *l* from [0, L], where $L = \lfloor (bi)/T_{ac} \rfloor$, *l*=0 is the first authentication control slot, and *bi* is the beacon interval.
f) The STA may initiate normal EDCA access procedures for the transmission of the Authentication-Request frame beginning at the authentication control slot *l* in the beacon interval *m*, where *m*=0 is the current beacon interval.
g) If the transmission of the Authentication-Request frame fails, the TI is increased as follows: $TI = \min\{2 \times TI, TI_{max}\}$.

An S1G AP may assign DAC parameters different from the default values by sending to the STA an Authentication Control element with the Control subfield equal to 1. An S1G STA receiving such an Authentication Control element shall update its MIB values of the DAC parameters based on the values received in the Authentication Control element.

11.4 TS operation

11.4.1 Introduction

There are three types of traffic specifications: the TSPEC, the DMG TSPEC, and the PTP TSPEC.

A TSPEC describes the traffic characteristics and the QoS requirements of a TS. The main purpose of the TSPEC is to reserve resources within the HC and, in the case of HCCA and HEMM access policies, to modify the HC's scheduling behavior. It also allows other parameters to be specified that are associated with the TS, such as a traffic classifier and ack policy.

The DMG TSPEC (9.4.2.132) describes an allocation (also known as DMG allocation) within either a PBSS or a DMG infrastructure BSS. The purpose of the DMG TSPEC is to create or modify an allocation for the transmission of frames between DMG STAs that are members of a PBSS or that are members of an infrastructure BSS (10.38.6).

To communicate between STAs in a PBSS or between non-AP DMG STAs in an infrastructure BSS, a TSPEC (as defined in 9.4.2.28) is used to create or modify a TS between those STAs. This TSPEC is referred to as a *PTP TSPEC*.

In a DMG BSS, a TSPEC includes parameters that are associated with the TS such as maximum MSDU size, delay bound, and optionally the allocation carrying the TS. A single allocation can carry multiple TSs. Each TS is carried in one allocation, except when

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The TS has an access policy of EDCA, where it can use all CBAP allocations with Source AID equal to the broadcast AID, all CBAP allocations with Source AID matching the source STA of the TS, and all CBAP allocations with Destination AID matching the destination STA of the TS; or
— The TS has an access policy of SEMM, where it can use exactly one SP allocation as well as all CBAP allocations with Source AID equal to the broadcast AID, all CBAP allocations with Source AID matching the source STA of the TS, and all CBAP allocations with Destination AID matching the destination STA of the TS.

A TS may have one or more TCLAS (within the discretion of the STA that sets up the stream) associated with it. A DMG STA or AP uses the parameters in the TCLAS elements to filter the MSDUs belonging to this TS for delivery as part of the TS. An Intra-Access Category Priority element may be associated with a TS by the inclusion of an Intra-Access Category Priority element in an ADDTS Request frame. The User Priority subfield of the Intra-Access Category Priority element shall be set to the same UP as specified in the User Priority subfield of the TS Info field. If dot11AlternateEDCAActivated is true, the Alternate Queue subfield is used to select the appropriate EDCA transmit queue when the Access Policy subfield of the TS Info field in the TSPEC is EDCA or HEMM. When an Intra-Access Category Priority element is associated with a TS, the Drop Eligibility subfield is used to indicate the drop eligibility of the MSDUs of this TS.

TS may have zero or one Expedited Bandwidth Request elements associated with it. An AP uses the parameters in the Expedited Bandwidth Request element, if present, to understand the precedence level requested by a non-AP STA (see R.5.4). For example, the precedence level may be used to convey to the AP that the requested TS is for the purposes of placing an emergency call. Support for precedence levels greater than 18 is optional for STAs.

TSPEC, PTP TSPEC, optional TCLAS, optional EBR, and optional Intra-Access Category Priority elements are transported over the WM by the ADDTS Request frame and the ADDTS Response frame, and across the MLME SAP by the MLME-ADDTS primitives. In addition, a TS could be created if a STA sends a resource request to an AP or PCP prior to initiating a transition to that AP or PCP, as part of performing FST (11.31), or in the Reassociation Request frame to that AP or PCP.

The DMG TSPEC is transported over the air within DMG ADDTS Request and DMG ADDTS Response frames and across the MLME SAP by the MLME-ADDTS primitives.

Following a successful negotiation, a TS is created, identified within the non-AP STA by its TSID and direction, and identified within the HC by a combination of TSID, direction, and STA address.

Following a successful negotiation of a DMG TSPEC in a PBSS or in a DMG infrastructure BSS, a new allocation is created, or an existing allocation is modified. Within a PBSS or infrastructure BSS, each allocation is uniquely identified by a combination of allocation ID, source AID, and destination AID.

Following a successful negotiation of a PTP TSPEC or a TSPEC in a DMG BSS, the frames corresponding to the PTP TSPEC or TSPEC are identified within the STA by the combination of TSID, requesting non-AP DMG STA address, and responding non-AP DMG STA address and direction.

It is always the responsibility of the non-AP STA to initiate the creation of a TS regardless of its direction. A STA that is not a DMG STA shall not transmit a PTP TSPEC or a DMG TSPEC. A non-AP DMG STA that is not the source DMG STA of a specific TS shall not initiate the exchange of a TSPEC to the AP DMG STA or PCP DMG STA to create that TS. Any non-AP DMG STA can issue a PTP TSPEC to any other non-AP DMG STA to create a TS.

In the TDLS direct link case, it is the responsibility of the STA that is going to send the data to create the TS. In this case, the STA negotiates with the HC to gain TXOPs that it uses to send the data. There is no negotiation

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

between the originator and recipient STAs concerning the TS: the originator can discover the capabilities of the recipient (rates, Block Ack) using the TDLS.

In the case of traffic relayed by an AP or PCP, the sending and receiving non-AP and non-PCP STAs may both create individual TS for the traffic. In an infrastructure BSS, any traffic classifier created for the downlink TS applies equally regardless of whether the source is in the same BSS or reached through the DS.

In a non-DMG infrastructure BSS, a non-AP STA may simultaneously support up to eight TSs from the HC to itself and up to eight TSs from itself to other STAs, including the HC. The actual number it supports may be less due to implementation restrictions.

In a non-DMG infrastructure BSS, an HC may simultaneously support up to eight downlink TSs and up to eight uplink TSs per associated STA. The actual number it supports may be less due to implementation restrictions.

In a DMG BSS there may be up to 16 TSs from a source DMG STA to a destination DMG STA. An additional 16 TSs may be created between the two DMG STAs by reversing the roles of source and destination. The actual number supported in any direction may be less due to implementation restrictions in either the source or destination DMG STA.

In a non-DMG BSS, the traffic admitted in the context of a TSPEC can be sent using EDCA, HCCA, or HEMM. This depends on the access policy set in the TS Info field in the TSPEC. A TSPEC request may be set so that both HCCA and EDCA mechanisms (i.e., HEMM) are used.

In a DMG BSS, the traffic admitted in the context of a PTP TSPEC or TSPEC is sent according to the access policy set in the TS Info field of the PTP TSPEC or TSPEC, respectively. Specifically, the traffic is sent during one or more CBAP allocations if the access policy is EDCA, during an SP allocation if the access policy is SPCA, and during one SP allocation as well as zero or more CBAP allocations if the access policy is SEMM.

A DMG STA transmitting a DMG TSPEC shall set the LP SC Used subfield within the DMG TSPEC to 1 to indicate that the low-power SC mode described in 21.7 is used during the allocation. All frames sent during such an allocation shall use the low-power SC mode. The STA shall set the LP SC Used subfield to 1 only if the STA identified in the Destination AID field within the DMG TSPEC supports the low-power SC mode (9.4.2.126.2). In all other cases, the LP SC Used subfield shall be set to 0.

When dot11SSPNInterfaceActivated is true, TSPEC processing by the HC may be subject to limitations received from the SSPN interface. The SSPN may limit access to certain QoS priorities, and further restrict the data rate and delay used with any priority.

11.4.2 TSPEC construction

TSPECs and DMG TSPECs are constructed at the SME, from application requirements supplied via the SME, and with information specific to the MAC.

The value of the Minimum PHY Rate in a TSPEC shall satisfy the following constraints:

a) For an uplink TS, it
   — Is included in dot11SupportedDataRatesTxTable and in the AP's operational rate set, or
   — Corresponds to an HT-MCS included in dot11SupportedHTMCSTxTable, if present, and in the AP's operational HT-MCS set, if defined, at a bandwidth and guard interval supported by the non-AP STA on transmission and permitted in the BSS, or
   — Corresponds to a VHT-MCS and NSS for which support is indicated by the combination of
      — The Tx VHT-MCS Map subfield in the VHT Operation parameter of the MLME-(RE)ASSOCIATE.request primitive, if present, and
      — The AP's operational VHT-MCS and NSS set, if defined, and

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The VHT Capabilities Information field

at a bandwidth and guard interval supported by the non-AP STA on transmission and permitted in the BSS.

b) For a downlink TS, it
   — Is included in the OperationalRateSet parameter of the MLME-JOIN.request primitive and supported by the AP on transmission,[44] or
   — Corresponds to an HT-MCS included in dot11SupportedHTMCSRxTable, if present, and supported by the AP on transmission, at a bandwidth and guard interval supported by the non-AP STA on reception and permitted in the BSS,[45] or
   — Corresponds to a VHT-MCS and NSS for which support is indicated by the combination of
      — The Rx VHT-MCS Map subfield in the VHT Operation parameter of the MLME-(RE)ASSOCIATE.request primitive, if present, and
      — The Tx VHT-MCS Map subfield of the VHT Operation element advertised by the AP, if present, and
      — The VHT Capabilities Information field

   at a bandwidth and guard interval supported by the non-AP STA on reception and permitted in the BSS.

c) For a bidirectional TS, it satisfies both a) and b) above.

See K.4 for a description of the parameter choice for the TSPEC.

NOTE—This standard states no requirements on how a DMG TSPEC is to be generated.

11.4.3 TS life cycle

Figure 11-24 summarizes the TS life cycle (using the HMSC syntax defined in ITU-T Recommendation Z.120 (2004).

Initially a TS is inactive. A STA shall not transmit any QoS Data frames in which the TID subfield of the QoS Control field matches an inactive TS.

A TS may be established by a Resource Request appearing in a message as part of a fast BSS transition from a STA. Such a TS is created in the accepted state. If the STA subsequently reassociates with this AP, then the TS becomes active. If the STA does not reassociate prior to the expiration of the reassociation timeout, then the TS becomes inactive.

Unless stated otherwise, in a DMG BSS, the owner of an SP is the source DMG STA for that SP, and the owner of a TXOP is the TXOP holder. A STA that owns an SP or a TXOP is said to have the ownership of the SP or the TXOP, respectively. The rules applicable to an SP or TXOP owner are defined in 10.38 and 11.4.

Following a successful TS setup initiated by a non-AP STA, the TS becomes active, and either the non-AP STA or the HC may transmit QoS Data frames whose TID contains this TSID (according to the Direction field). In the case of EDCA, the TID contains the UP value.

While the TS is active, the non-AP STA can attempt to renegotiate the parameters of the TSPEC characterizing the TS or the parameters of the DMG TSPEC characterizing the allocation carrying the TS.

[44] How a non-AP STA determines an AP's non-HT rate transmission support is implementation dependent. The non-AP STA might conservatively use the basic rate set, or it might use knowledge of past transmissions by the AP, or it might use other means.
[45] How a non-AP STA determines an AP's HT-MCS transmission support, if the Tx MCS Set subfield in the HT Capabilities element advertised by the AP is equal to 0 or if the Tx Rx MCS Set Not Equal subfield in that element is equal to 1, is implementation dependent. The non-AP STA might conservatively use the basic HT-MCS set, or it might use knowledge of past transmissions by the AP, or it might use other means.

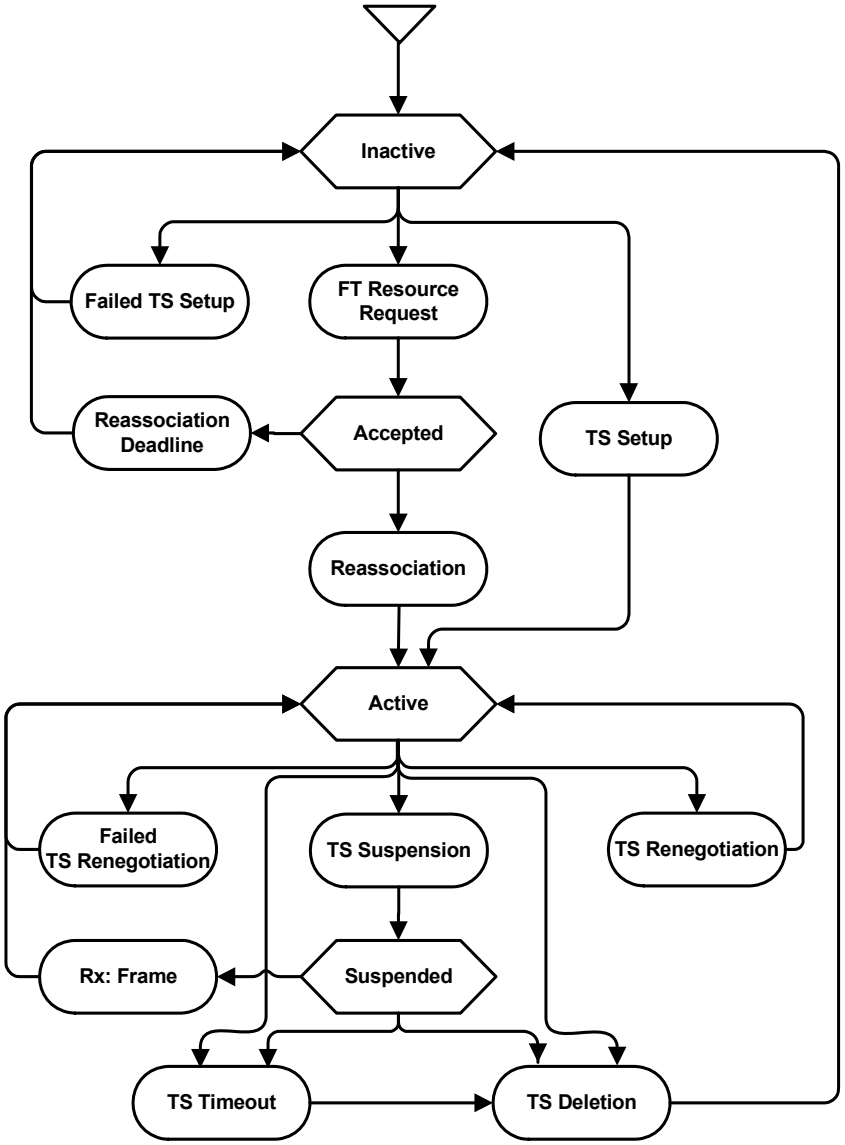

Figure 11-24—TS life cycle

An active TS becomes inactive following a TS deletion process initiated at either non-AP STA or HC. It also becomes inactive following a TS timeout detected at the HC, or if the HC within an AP when dot11SSPNInterfaceActivated is true determines as defined in 11.22.5 that the non-AP STA's TS has exceeded the transmitted MSDU limit for the access category in which the TS was admitted. In a DMG BSS, a TS timeout is detected at a non-AP STA and causes the TS deletion process to be initiated at the non-AP STA. When an active TS becomes inactive, all of the resources allocated for the TS are released.

An active TS may become suspended if no activity is detected for a duration of a suspension interval. Upon detection of activity, the TS may be reinstated. While the TS is in the suspended state, the HC shall not reclaim the resources assigned to the TS. In a DMG BSS, a TS in which both the source and destination are non-AP and non-PCP STAs shall not be suspended.

11.4.4 TS setup

11.4.4.1 General

A TS setup may be initiated by a non-AP STA or an AP.

11.4.4.2 Non-AP-STA-initiated TS setup

Figure 11-25 shows the sequence of messages occurring at a TS setup initiated by a non-AP STA. This message sequence in this figure and in the subsequent figures does not show the acknowledgment.

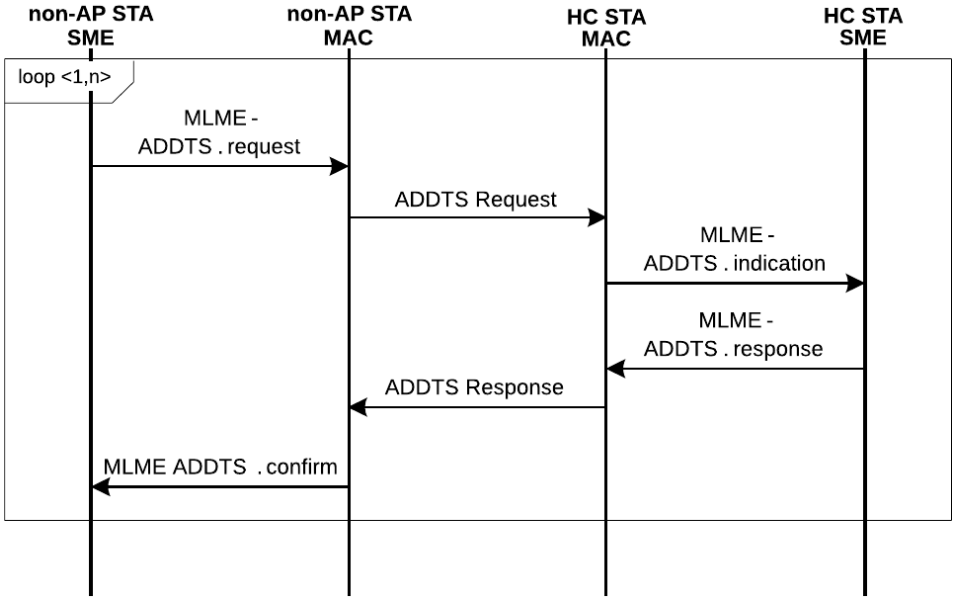

Figure 11-25—TS setup

11.4.4.3 AP-initiated TS setup

Figure 11-26 shows the sequence of messages occurring at a TS setup initiated by the AP. This message sequence in this figure and in the subsequent figures does not show the acknowledgments.

TS setup may be initiated by an AP in response to a request originating from higher layer protocols. An AP in which dot11RobustAVStreamingImplemented is true shall not send ADDTS Reserve Request frames to an associated STA that has set the RobustAVStreaming bit in the Extended Capabilities element in its (Re)Association Request frame to 0.

The higher layer stream ID is defined by the higher layer protocol. The Higher Layer Stream ID element shall be included in the ADDTS Reserve Request frame sent by the AP to the non-AP STA. This element is used in the TS setup procedure between the AP and the non-AP STA.

The AP initiates the TS setup by sending an ADDTS Reserve Request frame that includes the Higher Layer Stream ID element to the non-AP STA. On receipt of the ADDTS Reserve Request frame from the AP, the non-AP STA shall perform one of the following:

a) Complete the AP-initiated TS setup procedure by sending an ADDTS Reserve Response frame that includes the Higher Layer Stream ID element corresponding to the AP-initiated TS setup procedure and with the status code set to SUCCESS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

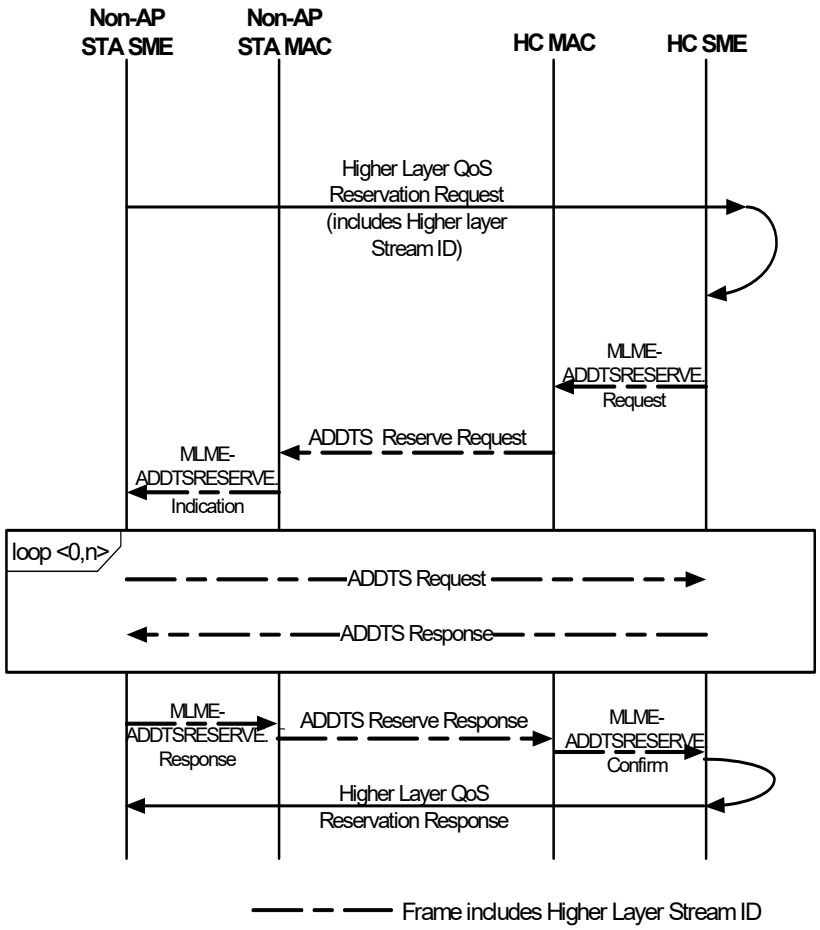

Figure 11-26—TS setup when initiated by the AP

b) Send an ADDTS Reserve Response frame with a status code not equal to SUCCESS and abort the AP-initiated TS setup. The Higher Layer Stream ID element in this ADDTS Reserve Response frame shall be set to the higher layer stream ID corresponding to the AP-initiated TS setup procedure.

c) Send an ADDTS Request frame to the AP. There might be multiple ADDTS Request/ADDTS Response exchanges between the non-AP STA and the AP, as described in 11.4.4.4, to negotiate the TSPEC parameters. The Higher Layer Stream ID element shall be included in all frames corresponding to the AP-initiated TS setup procedure that are exchanged between the non-AP STA and the AP. The AP-initiated TS setup procedure is completed by sending an ADDTS Reserve Response frame that includes the Higher Layer Stream ID element corresponding to the AP-initiated TS setup procedure and with the status code set to indicate the result of the TSPEC negotiation.

NOTE 1—Stream Reservation Protocol (SRP) as described in IEEE Std 802.1Q is an example of a higher layer protocol. The IEEE 802.11 subsystem at a non-AP STA does not interpret the SRP reservation request but simply sends it to the AP with which it is associated. A higher layer agent called *Designated Multiple Stream Registration Protocol (MSRP) Node (DMN)* is colocated with the AP in the device that supports SRP. All incoming SRP reservation requests are forwarded to the MSRP DMN. The MSRP DMN interprets the SRP reservation request and invokes appropriate IEEE 802.11 primitives in order for the AP to invoke the MLME-ADDTSRESERVE.request primitive. The MSRP DMN responds to the originator of the SRP Reservation request with the outcome of the AP-initiated TS setup procedure. The procedures performed by the MSRP DMN are described in IEEE Std 802.1Q.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 2—If the higher layer SRP Reservation Request message is lost within the IEEE 802.11 subsystem, the corresponding retry/recovery procedure is the responsibility of the SRP protocol. These procedures are described in IEEE Std 802.1Q.

11.4.4.4 TS setup procedures for both AP and non-AP STA initiation

The non-AP STA's SME decides that a TS needs to be created or non-AP HE STA traffic characteristics and QoS requirements need to be provided. The mechanism to provide traffic characteristics and QoS requirements is described in 26.5.8. How it does this, and how it selects the TSPEC or DMG TSPEC parameters, is beyond the scope of this standard. The SME generates an MLME-ADDTS.request primitive containing a TSPEC or DMG TSPEC. A TSPEC or DMG TSPEC may also be generated autonomously by the MAC without any initiation by the SME.

NOTE—Such a TSPEC or DMG TSPEC might be overridden as a result of a subsequent MLME-ADDTS.request primitive from the SME (see 11.4.4.5)

The STA's MLME transmits the TSPEC or DMG TSPEC in an ADDTS Request frame to the HC STA. If the non-AP STA's MLME is in power save mode, the STA shall include its DMG Wakeup Schedule element in the ADDTS Request frame variant and in the DMG ADDTS Request frame variant.

The HC STA's MLME receives this Management frame and generates an MLME-ADDTS.indication primitive to its SME containing the TSPEC or DMG TSPEC.

The SME in the HC STA decides whether to admit the TSPEC or DMG TSPEC with its associated TCLAS element(s) (if present) and TCLAS Processing element (if present), as specified, refuse the TSPEC or DMG TSPEC, or not admit but suggest an alternative TSPEC, DMG TSPEC, or TCLAS element(s), or TCLAS Processing element.

A DMG STA that responds with an ADDTS Response frame and an HC may change the value of parameters that have been set unspecified by the STA to any value that it deems appropriate, including leaving them unspecified.

If the TSPEC or DMG TSPEC is received from a non-AP STA by an AP when dot11SSPNInterfaceActivated is true, the HC shall use the permissions stored in dot11InterworkingEntry for that STA in the decision to admit or deny the request (see 11.22.5.3). The SME then generates an MLME-ADDTS.response primitive containing the TSPEC or DMG TSPEC, zero or more TCLAS element(s) (only if present in the request) and TCLAS Processing element (only if present in the request) and a ResultCode value. The Result Code field of the MLMEADDTS.response frame shall be set to one of the values in Table 11-7. The SME may include fewer TCLAS elements in the MLME-ADDTS.response primitive than were present in the request; when the SME's response includes a single TCLAS element, it shall not include a TCLAS Processing element. If the SME changes a TCLAS element's Classifier Type field in the MLME-ADDTS.response primitive but is unable to suggest a value for the Classifier Mask field, it shall set that field to 0. If the SME changes a TCLAS element's Classifier Type field or Classifier Mask field in the MLME-ADDTS.response primitive but is unable to suggest values for one or more Classifier Parameter subfields, it shall set those subfields to 0.

When the HC in an AP that has dot11SSPNInterfaceActivated equal to true receives a TSPEC, the AP shall inspect it to determine the requested access policy, user priority, and mean data rate as follows:

a) The access category shall be determined from the user priority according to Table 10-1. For a TS to be admitted when the requested access policy is EDCA, both of the following shall be true:
    1) The field corresponding to this access category in dot11NonAPStationAuthAccessCategories from the non-AP STA's dot11InterworkingEntry is equal to 1.
    2) The sum of the mean data rate of all of the requesting STA's active TSs in this access category plus the mean data rate in the TSPEC is less than or equal to the non-AP STA's dot11InterworkingEntry for dot11NonAPStationAuthMaxVoiceRate, dot11NonAPStation-

Table 11-7—Status Code for MLMEADDTS.response

Valid Range	Description
REJECTED_FOR_DELAY_PERIOD, REJECTED_WITH_SUGGESTED_BSS_TRANSITION, REQUESTED_TCLAS_NOT_SUPPORTED, TCLAS_RESOURCES_EXHAUSTED, REJECTED_HOME_WITH_SUGGESTED_CHANGES, REJECTED_FOR_SSP_PERMISSIONS, SUCCESS_STA_IN_PS_MODE, REJECT_U-PID_SETTING	Indicates the results of the corresponding MLMEADDTS.indication primitive

AuthMaxVideoRate, dot11NonAPStationAuthMaxBestEffortRate, or dot11NonAPStation-AuthMaxBackgroundRate depending on whether the derived access category is AC_VO, AC_VI, AC_BE or AC_BK, respectively.

b) For a TS to be admitted when the requested access policy is HCCA, all of the following shall be true:
   1) The dot11NonAPStationAuthHCCAHEMM value is true.
   2) The sum of the mean data rate of all of the requesting STA's active TSs having access policy set to HCCA plus the mean data rate in the TSPEC is less than or equal to dot11NonAPStationAuthMaxHCCAHEMMRate in the non-AP STA's dot11InterworkingEntry.
   3) The delay bound provided by the HC in the TSPEC response is less than or equal to dot11NonAPStationAuthHCCAHEMMDelay in the non-AP STA's dot11InterworkingEntry.

If the DMG TSPEC is admitted, the AP or PCP shall set the ResultCode to SUCCESS_STA_IN_PS_MODE if the STA identified by destination AID is in power save mode and shall include in the ADDTS Response frame the DMG Wakeup Schedule element of the destination DMG STA if one is established. In this case, the AP or PCP should defer including the TS schedule in the Extended Schedule element until both source DMG STA and destination DMG STA are in active mode.

The HC STA's MLME transmits an ADDTS Response frame containing this TSPEC or DMG TSPEC and status. The encoding of the ResultCode values to Status Code field values is defined in Table 9-80. The AP or PCP shall transmit the ADDTS Response frame to the STAs identified as source and destination AID of the DMG TSPEC contained in the ADDTS Request frame if the ADDTS request is sent by a non-AP and non-PCP STA. If the ResultCode is SUCCESS, the AP or PCP shall announce the creation of the allocation by setting the Allocation ID subfield in the TSPEC element sent in the ADDTS Response frame to a nonzero value and also by delivering the Extended Schedule element as defined in 10.38.6. In an AP when dot11SSPNInterfaceActivated is true, the HC shall set dot11NonAPStationAddtsResultCode in the non-AP STA's dot11InterworkingEntry equal to the ResultCode.

The STA's MLME receives this Management frame. It generates an MLME-ADDTS.confirm primitive to its SME containing the TSPEC or DMG TSPEC and status.

The SME decides whether the response meets its needs. How it does this is beyond the scope of this standard. An SME receiving a modified TCLAS element having a Classifier Mask field equal to 0 or Classifier Parameter subfields equal to 0 should regard these values as meaning that no suggested value has been provided by the HC.

— If the result code is SUCCESS, the TS enters into an active state.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— If the result code is REJECTED_WITH_SUGGESTED_BSS_TRANSITION, the non-AP STA should try to transition to one of the suggested BSSs according to the process defined in 11.21.7. Once the transition is completed, it should proceed with a TS setup process with the new HC.
— Otherwise, the whole process can be repeated using the same TSID and direction, a modified TSPEC or DMG TSPEC, optional TCLAS element(s), and an optional TCLAS Processing element until the SME decides that the granted medium time is adequate or inadequate and cannot be improved.

The above rules also apply to the negotiation of the PTP TSPEC and to the negotiation of the DMG TSPEC.

The parameters that are set for a TS may be renegotiated in a similar manner (see 11.4.4.5).

If the HC or PCP grants medium time for an ADDTS Request frame with the TS Info Ack Policy subfield equal to Block Ack and the Direction field equal to either downlink or bidirectional, then it shall initiate a block ack negotiation by sending an ADDBA Request frame to the STA that originated the ADDTS Request frame. If a non-DMG STA is granted medium time for an ADDTS Request frame with the TS Info Ack Policy subfield equal to Block Ack and the Direction field equal to other than downlink, then it shall initiate a block ack negotiation by sending an ADDBA Request frame to the recipient of the TS.

In a non-DMG BSS, the combination of the TSID and Direction subfields identify the TS, in the context of the STA, to which the TSPEC applies. A bidirectional link request is equivalent to a downlink TS and an uplink TS, each with the same TSID and parameters. In a DMG BSS, the combination of the TSID, source DMG STA AID, destination DMG STA AID, and Direction subfields identifies the TS, in the context of the non-AP STA, to which the TSPEC applies.

The same TSID may be used for multiple TSs at different STAs. A STA can use the same TSID subfield value for a downlink TSPEC and either an uplink or a direct link TSPEC at the same time. In a non-DMG BSS, a non-AP STA shall not use the same TSID for both uplink and direct link TS. In a DMG BSS, a non-AP STA as a source DMG STA can use the TSID subfield value for an uplink PTP TSPEC, and at the same time the non-AP STA as a destination DMG STA can use the same TSID subfield value for a downlink PTP TSPEC.

If the TS Info Ack Policy subfield of a TSPEC or DMG TSPEC element is Block Ack and the type of Block Ack policy is unknown to the HC, the HC assumes, for TXOP scheduling, that the immediate block ack policy is being used (see 10.25).

An HC shall support receiving an ADDTS Request frame that contains a TCLAS element and capable of generating an indication that contains this as a parameter.

When a STA requests service at a higher priority than authorized by its dot11InterworkingTableEntry, the HC may provide a suggested TSPEC or DMG TSPEC with a data rate and lower priority that would be authorized. Usage of the TSPEC in an Interworking environment is described in Annex K.

A STA may include a U-PID element in ADDTS Request, DMG ADDTS Request, ADDTS Response and DMG ADDTS Response frames it transmits. The U-PID element is used to indicate the upper layer protocol responsible for handling MSDUs corresponding to the TID indicated within the frame carrying the U-PID element. If a U-PID element is not included in an ADDTS Request, DMG ADDTS Request, ADDTS Response or DMG ADDTS Response frame, MSDUs corresponding to the TID contain an LLC header that is used for upper layer protocol identification.

A U-PID element shall not be included in an ADDTS Response or DMG ADDTS Response frame if a U-PID element was not included in the corresponding ADDTS Request or DMG ADDTS Request frame. If a U-PID element was included in an ADDTS Request or DMG ADDTS Request frame, the same U-PID element shall be included in the corresponding ADDTS Response or DMG ADDTS Response frame if that frame has a

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Status Code of SUCCESS. The Status Code field shall be set to REJECT_U-PID_SETTING in the ADDTS Response or DMG ADDTS Response frame if the request is rejected frame due to the setting of the U-PID element received; this frame may contain an alternative U-PID element that is acceptable to the STA sending the ADDTS Response or DMG ADDTS Response frame.

11.4.4.5 TS renegotiation

A non-AP STA may attempt to modify the parameters of a TSPEC or DMG TSPEC by transmitting an ADDTS Request or DMG ADDTS Request frame. If the status code in the corresponding ADDTS Response or DMG ADDTS Response frame is SUCCESS, then any TSPEC with the same TSID or DMG TSPEC with the same allocation ID is overridden with the TSPEC or DMG TSPEC in that frame, the HC and non-AP STA shall reset the inactivity interval timer, and the HC shall reset the suspension interval timer.

11.4.5 TS setup by resource request during a fast BSS transition

A QoS STA may transmit a TSPEC as part of a RIC-Request in a resource request message. The SME in the hybrid coordinator (HC) decides whether to accept the TSPEC as specified, or refuse the TSPEC, or not accept but suggest an alternative TSPEC. It then generates a RIC-Response, according to the procedures given in 13.11.

Each TS established by this resource request is placed in the accepted state. This state is an intermediate state between inactive and active. In the accepted state, the inactivity and suspension timers shall not be started for the TS. For a TS based on hybrid coordination function (HCF) controlled channel access (HCCA), the HC shall not generate CF-Poll for the TS.

The SME may take the resource/timing requirements of the TS in the accepted state into consideration before assigning any further resources to any other admitted or accepted TS, and in calculating the available admission capacity for the BSS Load element.

The TS is moved to the active state once the STA performs a reassociation to the AP (see 13.11.3). Once the TS becomes active, the inactivity and suspension timers are started. In an AP when dot11SSPNInterfaceActivated is true, the HC shall set dot11NonAPStationAddtsResultCode in the non-AP STA's dot11InterworkingEntry equal to the status code in the corresponding RDE.

If the reassociation timer times out and the TS is not yet in the active state, the TS goes back to the inactive state.

11.4.6 Failed TS setup

There are three possible types of failed TS setup:

a) The transmission of ADDTS Request frame failed.
b) No ADDTS Response frame is received from the HC STA (e.g., because of delay due to congestion or because the response frame cannot be transmitted).
c) An ADDTS Response frame is received that contains the Status Code field equal to REJECTED_FOR_DELAY_PERIOD. In this case, if the Delay field of the TS Delay element of the ADDTS Response frame is nonzero, the STA that transmitted the ADDTS Request frame shall not transmit another ADDTS Request frame to the same AP until the time indicated by the Delay field has elapsed.

Figure 11-27 summarizes the two cases. In either case in a non-DMG BSS, if the request is not for an existing TS, the SME shall issue a DELTS.request primitive to the HC specifying the TSID and direction of the failed request just in case the HC had received the request and it was the response that was lost. In either case in a DMG BSS, if the request is not for an existing allocation or TS, the SME shall issue a DELTS.request primitive

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

to the non-AP STA specifying the allocation ID or TSID and destination DMG STA of the failed request just in case the AP or PCP had received the request and it was the response that was lost.

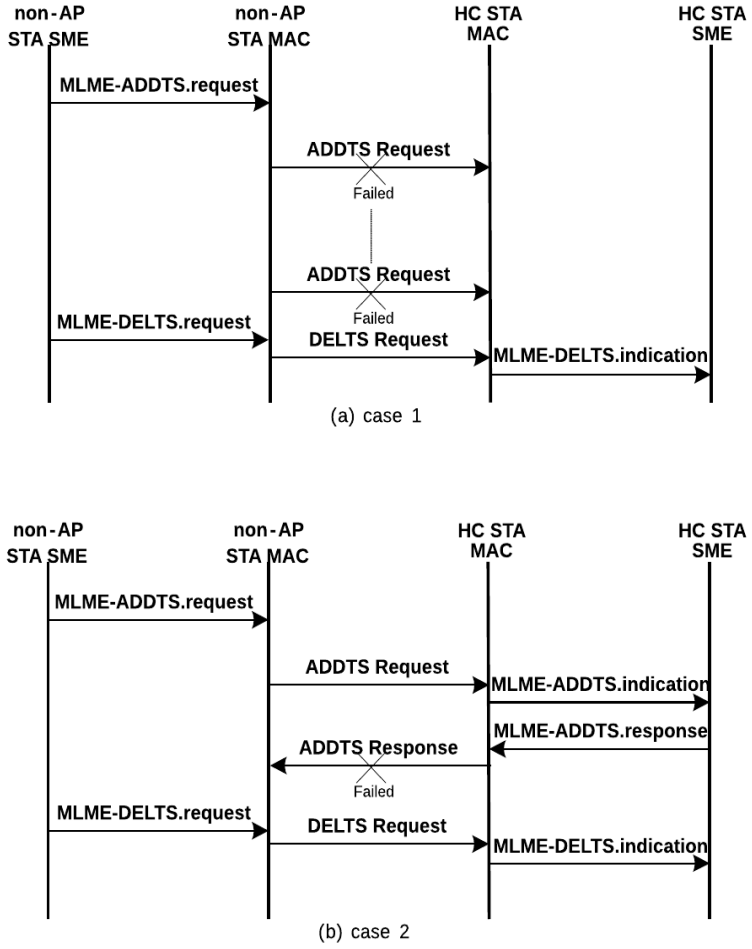

Figure 11-27—Failed TS setup detected within non-AP STA's MLME

11.4.7 Data transfer

After the setup of a TSPEC or PTP TSPEC, MSDUs are classified above the MAC and are sent to the MAC through the MAC SAP using the MA-UNITDATA.request primitive with the priority parameter encoded to the TID.

In a DMG BSS, MSDUs are transmitted using QoS Data frames. During each CBAP allocation, the MAC delivers MSDUs based on the priority of the transmitted QoS Data frames. The MAC can transmit all MSDUs having a TSID with an associated TSPEC with an access policy of EDCA or SEMM, provided that the source AID of the CBAP allocation is equal to the source AID of the TS, or the source AID of the CBAP allocation is equal to broadcast AID, or the destination AID of the CBAP matches the destination AID of the TS.

During each SP allocation, the MAC delivers MSDUs whose TSIDs identify TSPECs that have been set up to use the SP allocation. Relative prioritization of multiple TSPECs mapped to the same SP allocation is implementation dependent and outside the scope of this standard.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When an MSDU arrives from the MAC SAP with a TSID for which there is no associated TSPEC, the MSDUs shall be sent using EDCA with the access category AC_BE.

The generation of the associated TID is done by a classifier above the MAC, and it may use the associated TCLAS elements if any are present. When there are multiple TCLAS elements and if the Processing field of TCLAS Processing element is 0, the priority parameter in the associated MA-UNITDATA.request primitive is set to TID if the classifier matches the parameters in all of the TCLAS elements associated with the TS. When there are multiple TCLAS elements and if the Processing field of the TCLAS Processing element is 1, the priority parameter in the associated MA-UNITDATA.request primitive is set to TID if the classifier matches the parameters in at least one of the TCLAS elements associated with the TS. When there is no TCLAS element and if the Processing field of the TCLAS Processing element is 2, the priority parameter in the associated MA-UNITDATA.request primitive is set to TID if the classifier cannot match the parameters to any of the TCLAS elements. An incoming MSDU that is not classified to a particular TS may be classified to another active TS based on the frame classifier for that TS. If, however, all of the frame classifiers for the active TS have been exhausted, the MSDU does not belong to any active TS and is classified to be a best-effort MSDU. See 5.1.1.3 for the treatment of an MSDU with a TSID for which there is no associated TSPEC.

When an MSDU is classified using a TCLAS element, the original UP cannot be recovered by the receiver.

If dot11AlternateEDCAActivated is true, if an Intra-Access Category Priority element was provided when the TS was created, and if the Access Policy subfield of the TS Info field in the TSPEC is EDCA or HEMM, the value from the Alternate Queue subfield is used to select the appropriate EDCA transmit queue.

If an Intra-Access Priority element was provided when the TS was created, the Drop Eligibility subfield is used to determine the drop eligibility of the MSDU.

11.4.8 TS deletion

11.4.8.1 Deletion of a TS established between an HC, DMG AP, or PCP and a non-AP and non-PCP STA

The STA may delete a TS in either of two ways: using non-PCP and non-AP STA initiation or using HC, DMG AP or PCP initiation. In both methods, the SME generates an MLME-DELTS.request primitive specifying the TS to be deleted and the reason for deleting the TS. This causes the MAC to send a DELTS frame. The encoding of ReasonCode values to Reason Code field values is defined in Table 9-79.

Having transmitted a DELTS frame, the initiating MAC deletes the TS identified in the DELTS frame when it receives an Ack frame that responds to this DELTS frame. There is no Management frame response.

Figure 11-28 shows the case of TS deletion initiated by a non-PCP and non-AP STA and the case of TS deletion initiated by an HC, DMG AP, or PCP.

An HC should not delete a TSPEC without a request from the SME, except for inactivity (see 11.4.9) or an HC service change that precludes the HC from continuing to meet the requirements of the TSPEC.

All TSPECs that have been set up shall be deleted upon disassociation and reassociation. Reassociation causes the non-PCP and non-AP STA and HC, DMG AP, or PCP to clear their states, and the non-PCP and non-AP STA may then reinitiate the setup.

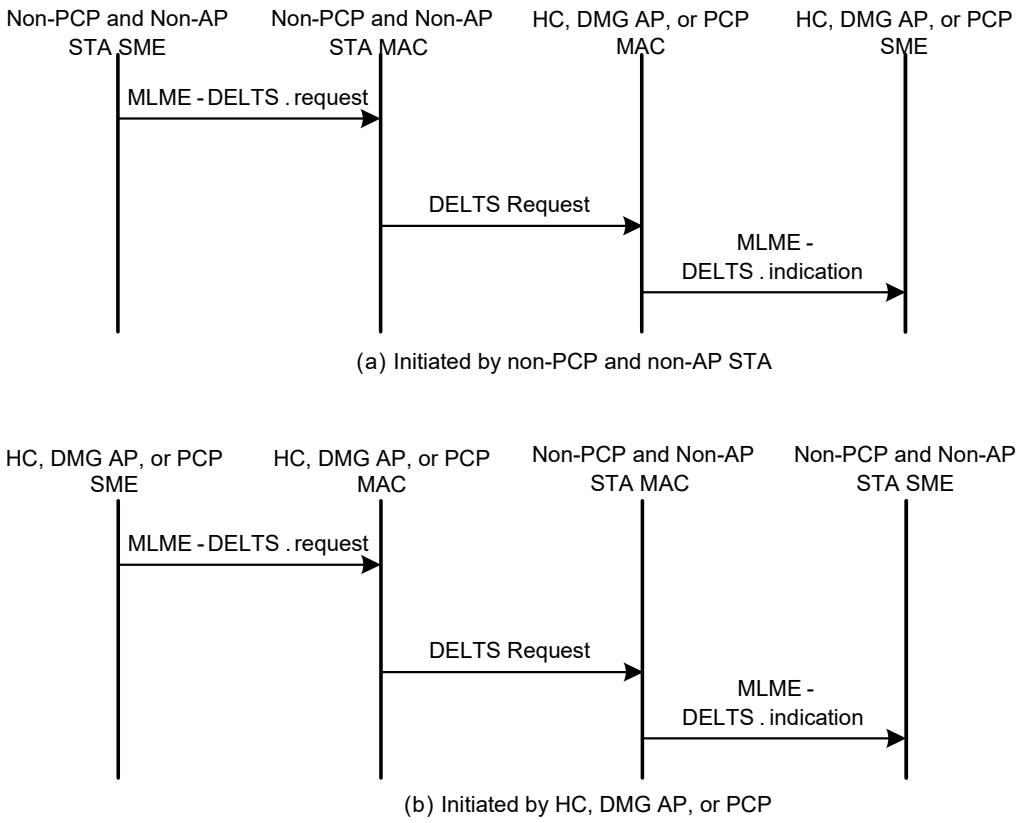

Figure 11-28—TS deletion

11.4.8.2 Peer-to-peer TS deletion and deletion of an allocation

This subclause describes deletion of a TS established between non-AP and non-PCP DMG STAs (i.e., established using a PTP TSPEC) and deletion of an allocation (i.e., established using a DMG TSPEC).

In this subclause the following procedures for deletion of an allocation or TS are described:

— Deletion of a TS established using a PTP TSPEC by either source or destination STAs
— Deletion of an allocation by either source or destination STAs of that allocation, which might result in the deletion of one or more associated TSs
— Deletion of an allocation (either SP or CBAP) by the AP or PCP

The SME generates an MLME-DELTS.request primitive specifying either the TS or the allocation to be deleted and the reason for deleting the TS or allocation, respectively. If generated within a non-AP and non-PCP STA, this primitive causes the MAC to send a single DELTS frame. If generated within an AP or PCP, this primitive causes the MAC to send one or two DELTS frames, as described below. The encoding of ReasonCode values to Reason Code field (see 9.4.1.7) values is defined in Table 9-79.

A STA that receives an MLME-DELTS.request primitive for a TS that was established using a PTP TSPEC causes the MAC to send a DELTS frame to the peer STA of the TS. This is shown in Figure 11-29 .

NOTE 1—The AP or PCP is unaware of the deletion of the TS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

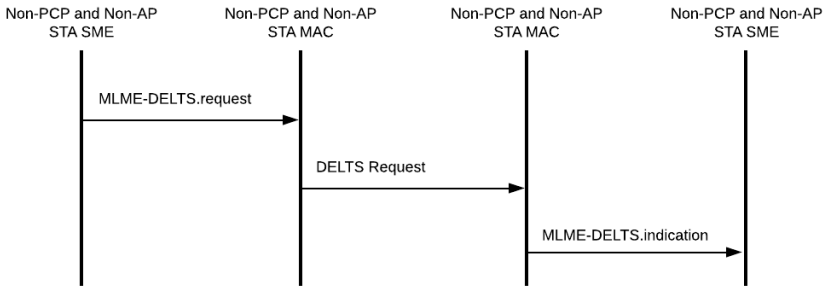

Figure 11-29—Deletion of a TS established using a PTP TSPEC

A non-AP and non-PCP STA that receives an MLME-DELTS.request primitive for an allocation causes the MAC to send a DELTS frame to the AP or PCP. If it is transmitted by the STA identified by the Source AID of the allocation and if the Destination AID of the allocation is different from the broadcast AID, the AP or PCP shall send a DELTS frame to the STA identified by the Destination AID of the allocation. If it is transmitted by the STA identified by the Destination AID of the allocation and if the Source AID of the allocation is different from the broadcast AID, the AP or PCP shall send a DELTS frame to the STA identified by the Source AID of the allocation. The AP or PCP shall also delete the scheduling information corresponding to the allocation, identified by the DMG Allocation Info field of the DELTS frame.

Figure 11-30 shows the deletion of an allocation in which both Source AID and Destination AID are not the broadcast AID.

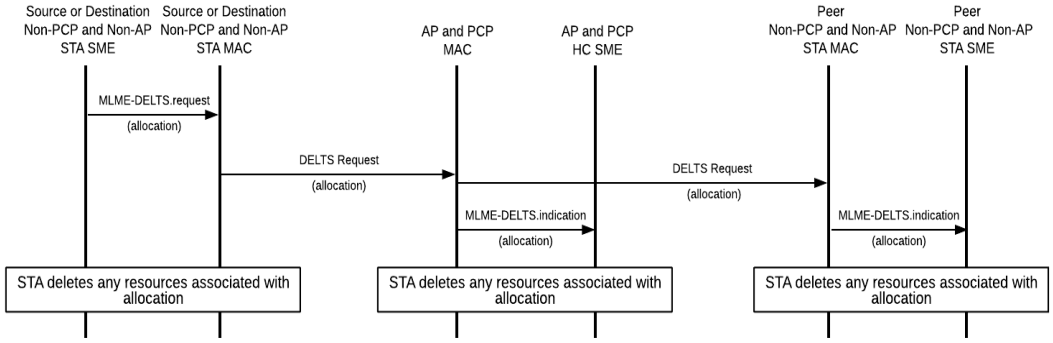

Figure 11-30—Deletion of an allocation in which both Source AID and Destination AID are not the broadcast AID

An AP or PCP that receives an MLME-DELTS.request primitive for an allocation causes the MAC to send one or two DELTS frames. If the Destination AID of the allocation is different from the broadcast AID, the AP or PCP shall send a DELTS frame to the STA identified by the Destination AID of the allocation. If the Source AID of the allocation is different from the broadcast AID, the AP or PCP shall send a DELTS frame to the STA identified by the Source AID of the allocation. The AP or PCP shall also delete the scheduling information corresponding to the allocation, identified by the DMG Allocation Info field of the DELTS frame.

An SME that deletes an allocation (using an MLME-DELTS.request primitive) or is notified that an allocation has been deleted (by receiving an MLME-DELTS.indication primitive) also locally deletes (i.e., updates it own resources, but does not cause any MAC frames to be transmitted) any TS that is dependent on that allocation as follows:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— Deleting an SP allocation shall also locally delete any TS with access policy SPCA or SEMM using the allocation.
— Deleting a CBAP allocation with Source AID different from the broadcast AID shall also locally delete any TS with access policy EDCA using the allocation.
— Deleting a CBAP allocation with Source AID equal to the broadcast AID shall also locally delete any TS with access policy EDCA using the allocation, unless there is another CBAP allocation the TS could use.

A non-AP and non-PCP STA that associates, disassociates or reassociates (except for reassociation to the same AP) shall locally delete all existing allocations and all TSs that have been established using a PTP TSPEC.

An AP or PCP that receives an MLME-ASSOCIATE.indication, MLME-REASSOCIATE.indication (except when the MLME-REASSOCIATE.indication primitive has this AP's MAC address in the CurrentAPAddress parameter) or MLME-DISASSOCIATE.indication primitive from a STA (the "resetting" STA) with which it has an existing association shall locally delete all allocations that have been established by the resetting STA using a PTP TSPEC. When deleting an allocation in which the Source AID or Destination AID correspond to the resetting STA and the peer STA is not identified by the broadcast AID, the AP or PCP shall send a DELTS to the peer STA to delete that allocation.

NOTE 2—If both Source AID and Destination AID are equal to the broadcast AID, the AP or PCP transmits no DELTS frames. It deletes scheduling information corresponding to the allocation, which is reflected in its subsequent transmission of frames containing an Extended Schedule element.

A STA that generates an MLME-ASSOCIATE.request, MLME-REASSOCIATE.request (except when the MLME-REASSOCIATE.request primitive has the target AP's MAC address in the CurrentAPAddress parameter) or MLME-DISASSOCIATE.request primitive shall locally delete all allocations and all TSs that have been established using a PTP TSPEC.

NOTE 3—Reassociation causes a STA to clear any state related to allocations and TSs that have been established using a PTP TSPEC. A non-PCP and non-AP STA might need to repeat the establishment of any allocations or TSs after reassociation needed to support applications active before the reassociation.

In all of the cases listed above, the TS or allocation is deleted within the initiating MAC when the Ack frame to the Action frame is received. No Action frame response is generated.

11.4.9 TS timeout

TS timeout is detected within the HC STA's MAC when no traffic is detected on the TS within the inactivity timeout specified when the TS was created.

For an uplink TS in a non-DMG BSS or for a TS that has the AP or PCP as the destination DMG STA in a DMG BSS, the timeout is based on the arrival of received MSDUs that belong to the TS, after any decryption and reassembly.

For a downlink TS in a non-DMG BSS or for a TS that has the AP or PCP as the source DMG STA in a DMG BSS, the timeout is based on the following:

— Arrival of valid MA-UNITDATA.request primitives using this TS at the MAC SAP when the QoS Data frames are sent with No Ack ack policy
— Confirmation of correctly sent MSDUs that belong to the TS within the MAC when the QoS Data frames are sent with ack policy other than No Ack

In a DMG BSS and in the case of a TS that is established between non-AP STAs (PTP TSPEC), the timeout of the recipient is based on the arrival of MSDUs that belong to the TS within the MAC after any decryption, A-MSDU unpacking, and reassembly.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In a TS established between non-AP STAs (PTP TSPEC), the timeout of the originator is based on the following:

— Arrival of valid MA-UNITDATA.request primitives using this TS at the MAC SAP when the QoS Data frames are sent with No Ack ack policy

— Confirmation of correctly sent MSDUs that belong to the TS within the MAC when the QoS Data frames are sent with ack policy other than No Ack

In a direct link TS in a non-DMG BSS, inactivity is considered to have happened if one of the two following events occurs:

— The HC transmits a QoS CF-Poll frame and the polled STA returns a QoS Null immediately after a SIFS that contains a QoS Control field in which the Queue Size subfield contains 0.

— The HC transmits a QoS CF-Poll frame, and no QoS Null frame is received within the granted TXOP duration that indicates the queue size for the related TSID. This is to confirm that the STA is actually using the assigned TXOP for the given TSID.

In a non-DMG BSS, any other use of a polled TXOP delivered to the STA is considered to be activity on all direct link TS associated with that STA. Detection of inactivity of this type is optional.

In response to an inactivity timeout, an HC shall send a DELTS frame to the STA with the reason code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive. In response to an inactivity timeout, a DMG AP shall send a DELTS frame to the non-AP DMG STA with the reason code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive. In response to an inactivity timeout, a PCP shall send a DELTS frame to the non-PCP DMG STA with the reason code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive.

In a DMG BSS when a TS is established between non-AP STAs (PTP TSPEC), then in response to a TS timeout detected within the originator non-AP STA the non-AP STA shall send a DELTS frame to the recipient non-AP STA with the reason code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive. If the TS timeout is detected within the recipient non-AP STA, the STA shall send a DELTS frame to the originator non-AP STA with the reason code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive.

The case of uplink TS timeout is shown in Figure 11-31 .

11.4.10 TS suspension

TS suspension occurs within the HC’s MAC when no traffic is detected on the TS within the suspension interval specified when the TS was created. In the suspended state, the generation of QoS (+)CF-Poll frames is stopped for the related TS.

11.4.11 TS reinstatement

A suspended TS may be reinstated following activity for that TS.

For uplink and direct link, a suspended TS may be reinstated by a STA by sending a QoS Data or QoS Null frame. This frame may be sent at the highest priority using EDCA. The generation of successive QoS (+)CF-Poll frames shall then be resumed by the HC.

For downlink, a suspended TS is reinstated by the HC when the AP receives an MSDU from a higher layer.

11.4.12 DMG allocation formats

11.4.12.1 General

A DMG STA manages allocations and TSs as described in 11.4.1 to 11.4.13. Using the DMG TSPEC element, a DMG STA can indicate two types of allocation scheduling: isochronous and asynchronous. It should establish an isochronous allocation if it needs periodic access to the channel and does not expect to change the amount of time allocated frequently. It should establish an asynchronous allocation if it expects to make requests for channel time and wishes to reserve a minimum amount of channel time to satisfy for those requests when they occur.

11.4.12.2 Isochronous allocations

In order to request the setup of an isochronous allocation, a DMG STA shall set the Allocation Format field in the DMG TSPEC element to 1.

An EDMG STA may request an SP allocation by using the BW, Channel Aggregation and Is Channel Number subfields in the DMG TSPEC element. To request a specific channel, the STA shall set the Is Channel Number subfield to 1 and set the BW subfield to the value of the requested channel; otherwise, the STA shall set the Is Channel Number subfield to 0 and set the BW subfield to the value of requested channel width. Upon reception of a DMG ADDTS Request frame that is admitted, an EDMG AP or EDMG PCP sets the Channel Aggregation subfield in the DMG ADDTS Response frame to the value of the Channel Aggregation subfield in the received DMG TSPEC element for the allocated channel, and sets the value of the BW field in the DMG TSPEC element of the DMG ADDTS Response frame sent in response to the ADDTS Request frame such that it meets the following requirements:

— If the Is Channel Number subfield in the received ADDTS Request frame is equal to 0, the AP or PCP may allocate a channel with channel width less than or equal to the value of the BW subfield in the received ADDTS Request frame.
— If the Is Channel Number subfield in the received ADDTS Request frame is equal to 1, the AP or PCP should allocate the channel as indicated by the BW subfield in the received ADDTS Request frame.

Following the successful admittance of a DMG TSPEC with an isochronous allocation, the AP or PCP should allocate time in the beacon interval to meet the periodicity and minimum allocation requirements specified in the DMG TSPEC element. If the PCP or AP is an EDMG STA and both the source and destination STAs of the DMG TSPEC are also EDMG STAs, the allocation time created by the AP or PCP should meet the bandwidth requirements specified in the DMG TSPEC element.

Referring to fields in the DMG TSPEC element, the AP or PCP should check that over each Allocation Period the sum of the time allocations is at least the Minimum Allocation. In addition, the AP or PCP should check that each individual allocation has a minimum duration of at least Minimum SP Duration. See 9.4.2.132, 10.38.6, and 10.38.6.4.

With an isochronous DMG TSPEC, the allocation period defines the period over which the channel time allocation repeats. The scheduler should check that at least the minimum allocation is made within each allocation period. The allocation may be composed of multiple SPs. The scheduler also checks that each SP making up the allocation is no shorter than the minimum SP duration. The scheduler is free to position the SPs that make up the allocation anywhere in the allocation period. The scheduler may allocate up to the maximum allocation each allocation period if resources permit.

11.4.12.3 Asynchronous allocations

A DMG STA uses the SPR frame to request channel time for asynchronous traffic.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

For each TID, source DMG STA, and destination DMG STA tuple, the AP or PCP can maintain the amount of outstanding channel time that needs to be allocated. Each time it receives an SPR frame, the amount of outstanding channel time is set to the value received in the SPR frame from the source DMG STA for the identified TID and destination DMG STA. The amount of outstanding channel time is decreased by the amount allocated when channel time is scheduled for that TID, source DMG STA, and destination DMG STA tuple.

A DMG STA may also use a DMG TSPEC to reserve resources for asynchronous traffic. In this case, the STA shall set the Allocation Format field in the DMG TSPEC element to 0. The AP or PCP should admit an asynchronous DMG TSPEC only if it is able to meet the minimum allocation requirements specified in the DMG TSPEC element.

With an asynchronous DMG TSPEC, a DMG STA registers the minimum allocation it expects within the allocation period while an SP request is in effect that is greater than the minimum allocation specified. In addition, the STA expects that each allocation is at least of duration specified by the Minimum Duration field of the DMG TSPEC, provided the outstanding SP request is at least that long. In admitting a DMG TSPEC, the AP or PCP should check that there are sufficient resources available to meet the TSPEC requirements.

An EDMG STA may request an SP allocation by transmitting an SPR frame with the CONTROL_TRAILER parameter in the TXVECTOR set to Present, CT_TYPE parameter in the TXVECTOR set to SPR, and then using the BW, Channel Aggregation and Is Channel Number subfields in the control trailer. To request a specific channel, the STA shall set the Is Channel Number subfield to 1 and set the BW subfield to the value of the requested channel; otherwise, the STA shall set the Is Channel Number subfield to 0 and set the BW subfield to the value of requested channel width. Upon reception of the SPR frame, an EDMG AP or EDMG PCP responds with a Grant frame that has the CONTROL_TRAILER parameter in the TXVECTOR set to Present and CT_TYPE parameter in the TXVECTOR set to GRANT_RTS_CTS2self. The EDMG AP or EDMG PCP sets the Channel Aggregation subfield in the Grant frame to the value of the Channel Aggregation subfield in the received SPR frame for the allocated channel, and sets the value of the BW field in the control trailer of the Grant frame such that the following requirements are met:

— If the Is Channel Number subfield in the control trailer of the received SPR frame is equal to 0, the AP or PCP may allocate a channel with channel width less than or equal to the value of the BW subfield in the received ADDTS Request frame.
— If the Is Channel Number subfield in the control trailer of the received SPR frame is equal to 1, the AP or PCP should allocate the channel as indicated by the BW subfield in the received ADDTS Request frame.

If the source DMG STA, destination DMG STA and the PCP or AP are all EDMG STAs, the allocation time created by the AP or PCP should meet the bandwidth requirements specified in the DMG TSPEC element or SPR frame, as appropriate, received by the AP or PCP.

11.4.13 PTP TSPEC operation

The ADDTS Request frame containing the PTP TSPEC may be sent to the peer non-AP DMG STA directly or through a DMG AP or PCP.

A non-AP DMG STA may add TSs to an existing allocation with a peer non-AP DMG STA. To do this, the non-AP DMG STA transmits an ADDTS Request frame to the peer STA to include the additional TS. The ADDTS Request frame shall contain a PTP TSPEC with the Allocation ID subfield set to indicate the allocation for the additional TS. A TS with EDCA access policy does not need to be added to any CBAP allocation and can use any CBAP allocation as long as the source AID of the CBAP allocation matches the source AID of the TS, or the source AID of the CBAP allocation is equal to the broadcast AID, or the destination AID of the CBAP matches the destination AID of the TS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A non-AP DMG STA transmits an ADDTS Request frame to a peer non-AP DMG STA to add a TS to an existing allocation and to possibly communicate traffic-specific parameters such as A-MSDU subframe and Maximum MSDU Size with the peer non-AP DMG STA. The non-AP DMG STA may transmit the ADDTS Request frame directly to the peer STA or to the AP or PCP. In the latter case, the ADDTS Request frame shall contain a TCLAS element with the classifier type set to Ethernet parameters; the Source Address field shall contain the address of the STA that sends the ADDTS Request frame; and the Destination Address field shall contain the address of the peer STA, which is used by the AP or PCP to forward to the peer STA.

The AP or PCP STA shall forward the received ADDTS Request frame to the STA with Address equal to the Destination Address field of the Classifier. If an ADDTS Response frame is received by the AP or PCP STA in response to the forwarded ADDTS Request frame, then the AP or PCP STA shall forward the ADDTS Response frame to the STA with Address equal to the Source Address field of the Classifier. The AP DMG STA and the PCP DMG STA shall not change the content of the elements included in the ADDTS Request and ADDTS Response frames.

If a STA sets the Direction field to a value equal to downlink in the PTP TSPEC included in the ADDTS Request frame, the parameters apply to the STA as the destination DMG STA of that TS. For example, in this case, the Maximum MSDU Size field indicates that the STA is not able to receive MSDUs longer than the value presented in the MSDU Size field. Similarly, if the Direction field indicates uplink, the parameters apply to the STA as the source DMG STA of that TS. In this case, the STA that issued the ADDTS Request frame does not send MSDUs longer than the value of the Maximum MSDU Size field.

11.5 Block ack operation

11.5.1 Introduction

Block ack agreements may be set up, modified by the originator, or deleted from the MAC (see 10.25.2 and 10.25.4) or from the SME. The setup, modification by the originator and deletion of block ack agreements from the SME is described in this subclause. All parameters of an agreement may be modified except for the TID. If the request is not successful, the existing agreement is not modified. If the request is successful, the behavior is as if a DELBA frame for the block ack agreement had been transmitted by the originator and received by the recipient immediately prior to the ADDBA Request frame.

11.5.2 Setup and modification of the block ack parameters

11.5.2.1 General

The procedures for setting up and modifying the block ack parameters are described in 11.5.2.2 and 11.5.2.3, respectively, and illustrated in Figure 11-32 .

11.5.2.2 Procedure at the originator

Upon receipt of an MLME-ADDBA.request primitive, in order to send QoS Data frames under the block ack mechanism, an initiating STA shall set up or modify a block ack agreement using the following procedure:

a) If the initiating STA is an HT STA, is an IBSS STA, and has no block ack agreement with the recipient STA, then the initiating STA shall transmit a Probe Request frame to the recipient STA and shall not transmit an ADDBA Request frame unless it receives a Probe Response frame from the recipient.

NOTE—When the block ack agreement is being established between a non-AP STA and its AP, then the originator and the recipient have exchanged capability information during the association exchange that allows them to determine whether the other STA is an HT STA.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

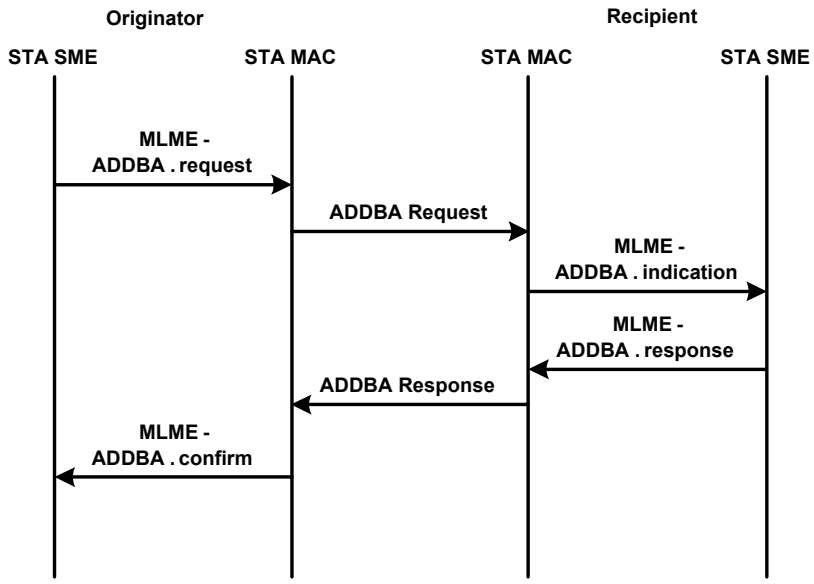

Figure 11-32—Block ack setup

b) If the peer STA is an S1G STA, the S1G originator shall send an NDP ADDBA Request to indicate that it expects only NDP BlockAck frames during the block ack agreement with the following exceptions:

   1) If the S1G originator's dot11BATImplemented is true and the BAT Support subfield in the most recently received S1G Capabilities element from the S1G recipient is 1 and a TWT has been set up with the S1G recipient as described in 10.46, then the S1G originator shall send a BAT ADDBA Request to indicate that it expects only BAT frames during the block ack agreement.

   2) When any of the conditions below is satisfied then the S1G originator may send an ADDBA request to indicate that it expects only BlockAck frames during the block ack agreement:

      i) The value of the Buffer Size field in the ADDBA Request, carried in an S1G_LONG or S1G_SHORT PPDU, is greater than 16.

      ii) The value of the Buffer Size field of the ADDBA Request, carried in an S1G_1M PPDU, is greater than 8.

      iii) The dot11AsymmetricBlockAckActivated is true and Asymmetric BA Supported field in the most recently received S1G Capabilities element from the S1G recipient is 1.

c) If the recipient is capable of participating, the originator sends an ADDBA Request frame indicating the TID and the buffer size. If the recipient is capable of participating and the GCRGroupAddress parameter of the MLME-ADDBA.request primitive is present, the originator sends an ADDBA Request frame that includes a GCR Group Address element. All DMG STAs are capable of participating in the block ack mechanism.

d) If an ADDBA Response frame is received with the matching dialog token and the TID and with a status code equal to SUCCESS, the STA has established or modified the block ack agreement with the recipient STA; and the MLME shall issue an MLME-ADDBA.confirm primitive indicating the successful completion of the setup or modification of the block ack agreement.

e) If an ADDBA Response frame is received with the matching dialog token and the TID and with a status code not equal to SUCCESS, the STA has not established or modified the block ack agreement with the recipient STA; and the MLME shall issue an MLME-ADDBA.confirm primitive indicating the failure of the setup or modification of the block ack agreement.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.5.2.3 Procedure at the recipient

A recipient shall operate as follows in order to support block ack agreement set up and modification:

a) When an ADDBA Request frame is received from another STA, the MLME shall issue an MLME-ADDBA.indication primitive.

b) Upon receipt of the MLME-ADDBA.response primitive, the STA shall respond by an ADDBA Response frame with a status code as defined in 9.6.4.3.

   1) If the status code is SUCCESS, the block ack agreement has been established or modified. Contained in the frame are the type of Block Ack agreement, the type of BlockAck frames, and the number of buffers that have been allocated for the support of this block. If the recipient STA is a non-AP S1G STA and it has received from the AP a frame containing an S1G Capabilities element with the Asymmetric BA Supported equal to 1, the Originator Preferred MCS field may be contained in the ADDBA Response frame.

   2) If the status code is REFUSED_REASON_UNSPECIFIED, the block ack agreement has not been established or modified.

The encoding of ResultCode values to Status Code field values is defined in Table 9-80.

For S1G STA, the ADDBA Response frame refers to

1) An NDP ADDBA Response if the value of the Buffer Size field of the NDP ADDBA Response is not greater than the value of the maximum number of MSDUs and A-MSDUs that can be acknowledged with the selected NDP BlockAck frame and no TWT has already been set up with the S1G originator as described in 10.46. This value is 8 for NDP 1M BlockAck frames and 16 for NDP_2M BlockAck frames as described in 23.3.12.2.6. The NDP ADDBA Response frame shall be carried in an S1G_1M PPDU to indicate the use of NDP_1M BlockAck frames and shall be carried in an S1G_SHORT or S1G_LONG PPDU to indicate the use of NDP_2M BlockAck frames.

2) Otherwise, a BAT ADDBA Response as a response to a BAT ADDBA Request if a TWT has already been set up with the S1G originator as described in 10.46. The value of the Buffer Size field in the BAT ADDBA Response shall not be greater than 32.

3) Otherwise, an ADDBA Response indicating the use of BlockAck frames. The MCS subfield in the Originator Preferred MCS field shall be set to 15 unless the dot11AsymmetricBlockAckActivated is true and the Asymmetric BA Supported field in the most recently received S1G Capabilities element from the S1G originator is 1, in which case the MCS subfield may indicate the value of the preferred MCS if asymmetric BA operation is used. The preferred MCS implicitly indicates the MCSDifference value, which is the difference between the preferred MCS and the MCS at which the ADDBA Response is sent.

11.5.2.4 Procedure common to both originator and recipient

Once a block ack agreement has been successfully established between two STAs, the type of agreement thus established is dependent on the capabilities of the STAs and the contents of the ADDBA Request and ADDBA

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Response frames used to establish this agreement as defined in Table 11-8 for non-DMG STAs and in Table 11-9 for DMG STAs that are not EDMG STAs, and in Table 11-10 for EDMG STAs.

Table 11-8—Types of block ack agreement based on capabilities and ADDBA conditions for non-DMG STAs

Capabilities condition	ADDBA condition	Type of block ack agreement
Both STAs are HT STAs.	Block Ack Policy subfield equal to 1	HT-immediate
Both STAs are robust AV streaming STAs, and the agreement was established using ADDBA Request/Response frames that included GCR Group Address elements.	Block Ack Policy subfield equal to 1	GCR Block Ack
Both STAs are S1G STAs	Block Ack Policy subfield equal to 1	HT-immediate

Table 11-9—Types of block ack agreement based on capabilities and ADDBA conditions for DMG STAs

Capabilities condition	ADDBA condition	Type of BlockAckReq and BlockAck variant	Type of block ack agreement
Both STAs have the BlockAck with Flow Control field in the DMG Capabilities element set to 1.	Block Ack Policy subfield equal to 0	Compressed	HT-immediate
At least one of the STAs has the BlockAck with Flow Control field in the DMG Capabilities element set to 0.	Block Ack Policy subfield equal to 0	Compressed	HT-immediate
At least one of the STAs has the BlockAck with Flow Control field in the DMG Capabilities element set to 0.	Block Ack Policy subfield equal to 1	Extended Compressed	HT-immediate
Both STAs have the BlockAck with Flow Control field in the DMG Capabilities element set to 1.	Block Ack Policy subfield equal to 1	Extended Compressed	HT-immediate + flow control

NOTE—If the BlockAckReq and BlockAck variant is Extended Compressed and the Type of block ack agreement is HT-immediate, use of the RBUFCAP field is implementation dependent.

11.5.3 Teardown of the block ack agreement

11.5.3.1 General

The procedure at the two STAs is described in 11.5.3.2 and 11.5.3.3 and illustrated in Figure 11-33 .

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

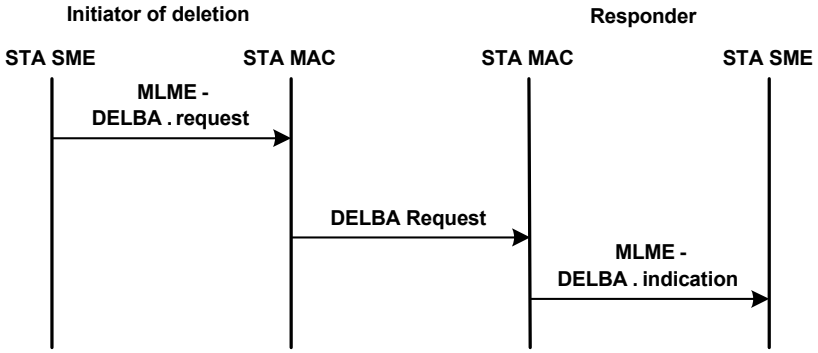

Figure 11-33—Block ack deletion

Table 11-10—Types of block ack agreement based on capabilities and ADDBA conditions for EDMG STAs

Capabilities conditions	ADDBA condition	Type of BlockAckReq and BlockAck variant	Type of block ack agreement
One of the STAs is a non-EDMG STA	Per Table 11-8	Per Table 11-8	Per Table 11-8
Both STAs are EDMG STAs	At least one STA indicates no support for EDMG flow control	Compressed BlockAckReq, EDMG Compressed BlockAck, and EDMG Multi-TID BlockAck	HT-Immediate + EDMG flow control (RBUFCAP with values Receiver Buffer Full, Receiver Buffer Empty, and No Memory Kept)
Both STAs are EDMG STAs	Both STAs indicate support for EDMG flow control	Compressed BlockAckReq, EDMG Compressed BlockAck, and EDMG Multi-TID BlockAck	HT-Immediate + EDMG flow control (RBUFCAP with values Receiver Buffer Full, Receiver Buffer Empty, and No Memory Kept) + EDMG flow control per Recipient Memory Capabilities field

11.5.3.2 Procedure at the initiator of the block ack agreement teardown

Upon receipt of an MLME-DELBA.request primitive, the MLME shall tear down the block ack agreement by transmitting a DELBA frame.

11.5.3.3 Procedure at the recipient of the DELBA frame

A STA shall issue an MLME-DELBA.indication primitive with the parameter ReasonCode having a value of REQUESTED when a DELBA frame is received.

11.5.3.4 Procedure at the block ack originator

When a block ack agreement is torn down, the originator shall, for MPDUs under that block ack agreement (i.e., recipient and TID), irrespective of whether it transmitted or received a DELBA frame, behave as follows.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the last (highest in sequence number space) MPDU transmitted was not acknowledged, and the originator wishes to retry this, the originator shall:

a) Discard all MPDUs that have not been acknowledged, up to and excluding the last (highest in sequence number space) MPDU transmitted, and

b) Retry that last MPDU first, outside the block ack agreement, retaining its sequence number.

NOTE—The MPDU cannot be retried in a subsequent new block ack agreement.

Otherwise, the originator shall:

a) Discard all MPDUs that have not been acknowledged, up to and including the last (highest in sequence number space) MPDU transmitted, and

b) Set the sequence number of the next MPDU to be transmitted outside the block ack agreement to a sequence number after (in sequence number space) that of the last (highest in sequence number space) MPDU transmitted.

11.5.3.5 Procedure at the block ack recipient

When a block ack agreement is torn down, the recipient shall, irrespective of whether it transmitted or received a DELBA frame, set the last sequence number received value for MPDUs for the block ack agreement's originator and TID to the sequence number of the last (highest in sequence number space) MPDU received, regardless of the ack policy used in that MPDU.

11.5.4 Error recovery upon a peer failure

Every STA shall maintain an inactivity timer for every negotiated block ack setup, unless the block ack agreement is set up for a GCR group address. The inactivity timer at a recipient is reset when MPDUs with the TID for the block ack agreement are received and the ack policy is Block Ack or Implicit BAR. The inactivity timer is not reset when MPDUs corresponding to other TIDs are received. The inactivity timer at the recipient is also reset when a BlockAckReq frame with the TID for the block ack agreement is received. The inactivity timer at the originator is reset when a BlockAck frame with the TID for the block ack agreement is received. When a block ack agreement inactivity timeout occurs, the STA shall send a DELBA frame to the peer STA with the Reason Code field set to TIMEOUT and shall issue an MLME-DELBA.indication primitive with the ReasonCode parameter having a value of TIMEOUT. The procedure is illustrated in Figure 11-34 .

When a recipient does not have an active block ack agreement for a TID, but receives one or more QoS Data frames with Block Ack ack policy, it shall discard them and shall send a DELBA frame. When a recipient does not have an active block ack agreement for a TID, but receives a BlockAckReq frame, it may respond with an Ack frame and shall send a DELBA frame. The originator may attempt to set up a block ack agreement again or may send MPDUs using an alternative acknowledgment mechanism.

11.6 Higher layer timer synchronization

11.6.1 Introduction

Higher layer timer synchronization is beyond the scope of this standard. However, explanation of how the constructs in this standard might be used to support such capabilities might be useful to the designer.

One way to accomplish synchronization across a BSS is by multicasting synchronization (sync) packets from the higher layers containing a time stamp and a sequence number. These packets would be opaque to the MAC and would be transported in the same way as any other MSDU (most likely addressed to the group address). Sync packets would be treated as a type of management packet by the higher layers. The time stamp in the sync packet would contain the higher layer clock value at the time when the previous sync packet was transmitted.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

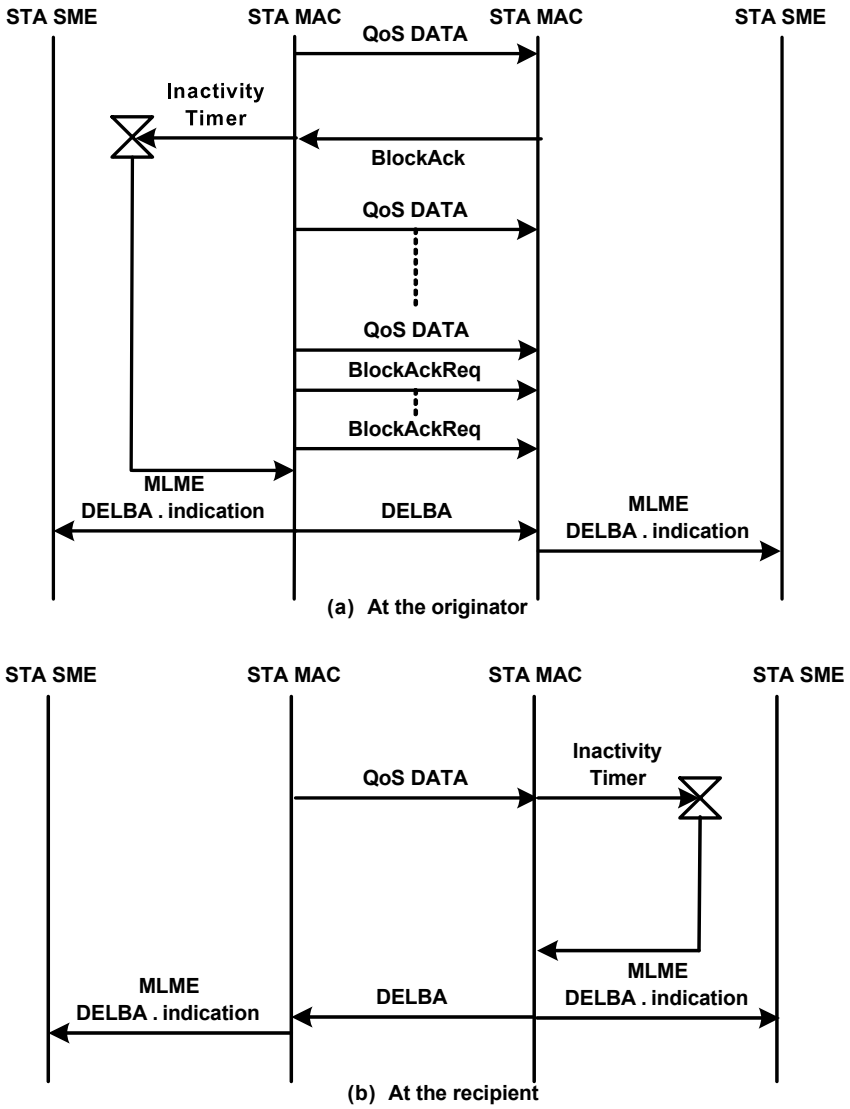

Figure 11-34—Error recovery by the receiver upon a peer failure

The sequence number parameter has a value equal to the sequence number of the MSDU in which the time stamp is provided.

The reason the packet would contain the time stamp for the previous sync packet (rather than the current packet) is that hardware and layering constraints would prohibit the ability to provide a time stamp for the exact instant the current packet is transmitted within that packet. However, an MLME-HL-SYNC.indication primitive allows the transmitting STA to know exactly when each sync packet is transmitted. A receiving STA might note the time when each sync packet is received as well as the sequence number for that frame. The receiving STA would save this receive time indication for each packet along with its sequence number and compare the indication of the previously received sync packet to the time stamp in the most currently received packet. This comparison allows the STA to compute an offset, which can be used to adjust its time reference to match that of the synchronization source. A check of the sequence number verifies that the correct packet is being used for time stamp comparison. It is possible a packet is lost; in this case, the received time stamp for the lost packet should be discarded.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The end of the PPDU[+SigExt] containing the sync packet is indicated by the PHY using the PHY-TXEND.confirm and PHY-RXEND.indication primitives in the transmitter and receiver of the sync packet, respectively. Practical limits on the coincidence of this indication and the end of the PPDU[+SigExt] containing the sync packet are implementation dependent. The accuracy of this technique also depends on the propagation delay between the source and receiving channel. However, both the time difference (between the PHY indication and the end of the PPDU[+SigExt] containing the sync packet) and the propagation delay can be considered as fixed-delay components. Therefore, they contribute only to the fixed time difference between the transmitter and receiver STAs' clocks and do not contribute to jitter. An implementation dependent scheme might be used to cancel or minimize this fixed time difference.

The sync packet may also be relayed through the AP. In this case, the STA that generates the time stamps notes the reception of the group addressed sync packet from the AP as the indication to save the higher clock value for the next sync packet. Receiving STAs would also similarly note the time when each sync packet is received from the AP. The sequence number would include a value corresponding to the frame received from the AP.

This is an example implementation using the higher layer timer synchronization feature. Other implementations are possible.

11.6.2 Procedure at the STA

In order to determine whether to provide an MLME-HL-SYNC.indication primitive for a particular Data frame, a MAC that supports MLME-HL-SYNC primitives compares the Address 1 field in a Data frame's MAC header to a list of group addresses previously registered by an MLME-HL-SYNC.request primitive.

When the MAC transmits a Data frame with an Address 1 match, the MLME-HL-SYNC.indication shall occur when the end of the PPDU[+SigExt] carrying the Data frame is transmitted. When the MAC receives a Data frame with an Address 1 match, the MLME-HL-SYNC.indication shall occur when the end symbol of the PPDU[+SigExt] carrying the matching Data frame is received. In both cases, the MLME-HL-SYNC.indication primitive provided is simultaneous (within implementation dependent delay bounds) with the indication provided to other STAs within the BSS for the same Data frame.

11.7 TPC procedures

11.7.1 General

Regulations in most regulatory domains require RLANs operating in the 5 GHz band or 6 GHz band to use transmitter power control, involving specification of a regulatory maximum transmit power and a mitigation requirement for each allowed channel. This standard describes such a mechanism, referred to as *transmit power control (TPC)*.

This subclause describes TPC procedures intended to satisfy needs in many regulatory domains and other frequency bands. These procedures might be useful for other purposes (e.g., reduction of interference, range control, reduction of power consumption).

A STA shall use the TPC procedures defined in 11.7 if dot11SpectrumManagementRequired is true. dot11SpectrumManagementRequired shall be set to true when regulatory authorities require TPC. It may also be set to true in other circumstances. The TPC procedures provide for the following:

— Association of STAs with an AP or PCP in a BSS based on the STAs' power capability (see 11.7.2)
— Peering of mesh STAs based on the mesh STAs' power capability (see 11.7.3)
— Specification of regulatory and local maximum transmit power levels for the current channel (see 11.7.5)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— Selection of a transmit power for each transmission in a channel within constraints imposed by regulatory and local requirements (see 11.7.6)
— Adaptation of transmit power based on a range of information, including path loss and link margin estimates (see 11.7.7)

If dot11SpectrumManagementRequired is true, a non-DMG STA shall not join an infrastructure BSS, MBSS or IBSS unless the Spectrum Management bit is 1 in the Capability Information field in Beacon frames and Probe Response frames or in the Condensed Capability Information field in Measurement Pilot frames received from other STAs in the BSS, with the following exceptions:

— A STA may operate when the Spectrum Management bit is 0 if the STA determines that it is in a regulatory domain that does not require TPC or determines that it meets regulatory requirements even if TPC is not employed. Potential methods for determining the regulatory domain include receiving a country indication in the Beacon frame, Measurement Pilot frame, user confirmation, or configuration information within the device. Potential methods to meet regulations even if TPC is not employed include using a transmit power that is below the legal maximum (including any mitigation factor).
— A STA shall set dot11SpectrumManagementRequired to true before associating with a BSS in which the Spectrum Management bit is 1 in the Capability Information field in Beacon frames and Probe Response frames or in the Condensed Capability Information field in Measurement Pilot frames received from the BSS.
— An AP may allow association of devices that do not have the Spectrum Management bit equal to 1 in the Capability Information field in Association Request frames and Reassociation Request frames received from the STA to account for the existence of legacy devices that do not support TPC, but do meet regulatory requirements.

A mesh STA shall set dot11SpectrumManagementRequired to true before becoming a member of an MBSS in which the Spectrum Management bit is equal to 1 in the Capability Information field in Beacon frames and Probe Response frames received from the MBSS.

A DMG STA that has dot11ExtendedTPCActivated defined and with a value different from none shall support the Extended TPC as defined in 10.42.6 (Extended TPC).

11.7.2 Association based on transmit power capability

A STA shall inform an AP or PCP of its minimum and maximum transmit power capability for the current channel when associating or reassociating, using a Power Capability element in (Re)Association Request frames.

An AP or PCP might use the minimum and maximum transmit power capability of associated STAs as an input into an algorithm used to determine the local transmit power constraint for any BSS it maintains. The specification of the algorithm is beyond the scope of this standard.

An AP or PCP may reject a (re)association request from a STA if it considers the STA’s minimum or maximum transmit power capability to be unacceptable. For example, a STA’s power capability might be unacceptable if it violates local regulatory constraints or increases the probability of hidden STAs by a significant degree. The criteria for accepting or rejecting a (re)association on the basis of transmit power capability are beyond the scope of this standard.

If a STA sends a Country element, a Power Constraint element, and a Transmit Power Envelope element, where the interpretation of the Maximum Transmit Power Level field in the Country element for a 20 MHz or 40 MHz Subband Triplet field is the same as the Maximum Transmit Power Interpretation subfield, then at least one of local power constraints indicated by the Maximum Transmit Power For 20 MHz and Maximum

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Transmit Power For 40 MHz fields in the Transmit Power Envelope element shall be the same as the indicated local power constraint expressed by the combination of Country element and Power Constraint element.

NOTE—An example of the interpretation of the Maximum Transmit Power Level field in the Country element for a 20 MHz or 40 MHz Subband Triplet field being the same as the Maximum Transmit Power Interpretation subfield is when both are EIRP.

11.7.3 Peering based on transmit power capability

A mesh STA shall provide a candidate peer mesh STA with its minimum and maximum transmit power capability for the current channel when becoming a member of an MBSS, using a Power Capability element in Mesh Peering Open frames.

A mesh STA may use the minimum and maximum transmit power capability of a neighbor peer mesh STA as an input into the algorithm used to determine the local transmit power constraint. The specification of the algorithm is beyond the scope of this standard.

A mesh STA may reject a Mesh Peering Open request from a candidate mesh STA if it considers the candidate mesh STA's minimum or maximum transmit power capability to be unacceptable. For example, a candidate mesh STA's power capability might be unacceptable if it violates local regulatory constraints. The criteria for establishing or rejecting a Mesh Peering Open request on the basis of transmit power capability are beyond the scope of this standard.

If a STA sends a Country element, a Power Constraint element, and a Transmit Power Envelope element, where the interpretation of the Maximum Transmit Power Level field in the Country element for a 20 MHz or 40 MHz Subband Triplet field is the same as the Maximum Transmit Power Interpretation subfield, then at least one of the local power constraints indicated by the Maximum Transmit Power For 20 MHz field or Maximum Transmit Power For 40 MHz field in the Transmit Power Envelope element shall be the same as the indicated local power constraint expressed by the combination of Country element and Power Constraint element.

11.7.4 Interpretation of transmit power capability

As regards the units of the Minimum Transmit Power Capability and Maximum Transmit Power Capability fields within the Power Capability element sent in a STA's (Re)Association Request frame to an AP, if all of the following apply:

— The STA is extended spectrum management capable.
— The STA has dot11SpectrumManagementRequired or dot11RadioMeasurementActivated equal to true.
— A Beacon or Probe Response frame has been received from the AP by the STA.
— The Beacon or Probe Response frame includes one or more Transmit Power Envelope elements.

then

— The units shall be interpreted according to the Local Maximum Transmit Power Unit Interpretation subfield in the Transmit Power Information field in the first or only Transmit Power Envelope element (see 9.4.2.160) sent in the most recently received Beacon or Probe Response frame from the AP.

Otherwise

— The units shall be interpreted as EIRP.

If the Beacon or Probe Response frame most recently received from a neighbor mesh STA by a mesh STA that is extended spectrum management capable and that has dot11SpectrumManagementRequired or

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

dot11RadioMeasurementActivated equal to true includes one or more Transmit Power Envelope elements, then the units of the Minimum Transmit Power Capability and Maximum Transmit Power Capability fields within the Power Capability element sent in the Mesh Peering Open frame to the neighbor mesh STA shall be interpreted according to the Local Maximum Transmit Power Unit Interpretation subfield in the first or only Transmit Power Information field in the Transmit Power Envelope element (see 9.4.2.160) sent in the most recently received Beacon or Probe Response frame from the AP. Otherwise, the units of the Minimum Transmit Power Capability and Maximum Transmit Power Capability fields within the Power Capability element sent in the mesh STA's Mesh Peering Open frame to the neighbor mesh STA shall be interpreted as EIRP.

11.7.5 Specification of regulatory and local maximum transmit power levels

A STA shall determine a regulatory maximum transmit power for the current channel by selecting the minimum of the following:

- Any regulatory maximum transmit power received in a Country element from the AP in its BSS, PCP in its PBSS, another STA in its IBSS, or a neighbor peer mesh STA in its MBSS
- If the STA is extended spectrum management capable, any regulatory client maximum transmit power applicable to the STA (see E.2) that is received in a Transmit Power Envelope element from the AP in its BSS, another STA in its IBSS, or a neighbor peer mesh STA in its MBSS.
- Any regulatory maximum transmit power for the channel in the current regulatory domain known by the STA from other sources

A STA shall determine a local maximum transmit power for the current channel by selecting the minimum of the following:

- Unless the STA is extended spectrum management capable and has received a Transmit Power Envelope element for a channel width of 20 MHz and 40 MHz, any local maximum transmit power received in the combination of a Country element and a Power Constraint element from the AP in its BSS, PCP in its PBSS, another STA in its IBSS, or a neighbor peer mesh STA in its MBSS
- If the STA is extended spectrum management capable, any local maximum transmit power applicable to the STA (see E.2) that is received in a Transmit Power Envelope element from the AP in its BSS, another STA in its IBSS, or a neighbor peer mesh STA in its MBSS
- Any local maximum transmit power for the channel in the current regulatory domain known by the STA from other sources

NOTE 1—A STA might receive a maximum transmit power in a Transmit Power Envelope element from the AP in its BSS, another STA in its IBSS, or a neighbor peer mesh STA in its MBSS in various management frames, including Beacon frames, Probe Response frames, FILS Discovery frames, and (prior to a channel switch) New Transmit Power Envelope elements (in Channel Switch Wrapper elements, Future Channel Guidance elements, Channel Switch Announcement elements/frames, or Extended Channel Switch Announcement elements/frames). Other sources from which a STA might receive a maximum transmit power for a channel include Reduced Neighbor Report elements (20 MHz PSD subfield) sent by a (colocated) AP. If this information is received by a STA, any requirements on its usage depend on local regulations known at the STA (see E.2).

NOTE 2—The determination of a maximum transmit power from Transmit Power Envelope element(s) is specified in 10.22.4.

The Local Power Constraint field of any transmitted Power Constraint element and each Maximum Transmit Power For *X* MHz subfield (where *X* = 20, 40, 80, or 160/80+80) in the Transmit Power Envelope element shall each be set to its respective value that allows the mitigation requirements to be satisfied in the current channel.

NOTE 3—The local maximum transmit power for the channel needs to meet the mitigation requirements for the channel in the current regulatory domain. The conservative approach is to set the local maximum transmit power level equal to the regulatory maximum transmit power level minus the mitigation requirement. However, it might be possible to satisfy

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the mitigation requirement using a higher local maximum transmit power level. A lower local maximum transmit power level might be used for other purposes (e.g., range control, reduction of interference).

The regulatory and local maximum transmit powers may change in a STA during the life of an infrastructure BSS and an MBSS. However, network stability needs to be considered when deciding how often or by how much these maximums are changed. The regulatory and local maximum transmit powers shall not change during the life of an IBSS.

An AP, IBSS STA or mesh STA that is not operating in the 6 GHz band shall advertise the regulatory maximum transmit power for that STA's operating channel in Beacon frames and Probe Response frames using a Country element. An AP, IBSS STA or mesh STA shall advertise the local maximum transmit power for that STA's operating channel in Beacon frames and Probe Response frames using the combination of a Country element and a Power Constraint element.

If an AP, IBSS STA, or mesh STA that is not operating in the 6 GHz band is extended spectrum management capable, it shall advertise the local maximum transmit power for that STA's operating channel in Beacon frames and Probe Response frames using one Transmit Power Envelope element for each distinct value of the Maximum Transmit Power Interpretation subfield that is supported by the BSS, IBSS, or MBSS, respectively. Each Transmit Power Envelope element shall include a local power constraint for all channel widths supported by the BSS.

If an AP, IBSS STA, or mesh STA is operating in the 6 GHz band, it shall include Transmit Power Envelope element(s) in Beacon and Probe Response frames as follows:

a) For each distinct combination of values of the Maximum Transmit Power Interpretation subfield and Maximum Transmit Power Category subfield that are supported by the BSS, IBSS, or MBSS, respectively, one Transmit Power Envelope element is included that indicates the regulatory client maximum transmit power for the STA's operating channel.
b) At a minimum, a regulatory client maximum transmit power is indicated where the Maximum Transmit Power Category subfield is set to 0 (Default).
c) If a local maximum transmit power is lower than a regulatory client maximum transmit power for the same combination of values of the Maximum Transmit Power Interpretation subfield and Maximum Transmit Power Category subfield, a Transmit Power Envelope element is included that indicates that local maximum transmit power.
d) Each Transmit Power Envelope element that is included indicates a power constraint for all channel widths supported by the BSS (if an EIRP constraint is advertised) or for all 20 MHz channels within the bandwidth of the BSS (if an EIRP PSD constraint is advertised).

NOTE 4—The regulatory client maximum transmit power is the regulatory limit for client devices, such as non-AP STAs, which might be different from the regulatory limit for APs.

NOTE 5—STAs operating in the 6 GHz band are extended spectrum management capable (see 10.22.3).

NOTE 6—If a Transmit Power Envelope element in a Beacon or Probe Response frame in the 6 GHz band indicates EIRP PSD limits, the value of N (see Table 9-320) is either equal to 0 or equal to the BSS bandwidth, in megahertz, divided by 20 (i.e., 1, 2, 4, or 8 for 20, 40, 80, or 160/80+80 MHz BSS bandwidth, respectively).

NOTE 7—An AP, IBSS STA, or mesh STA does not need to send Transmit Power Envelope elements indicating maximum transmit EIRP if it sends Transmit Power Envelope elements indicating maximum transmit PSD and those PSD values are sufficient to ensure regulatory limits on total EIRP are always met for all transmission bandwidths of STAs in the BSS.

STAs that are extended spectrum management capable and have dot11RadioMeasurementActivated equal to true should be able to reduce their EIRP to 0 dBm.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 8—When the local maximum transmit power is set by an AP for radio resource management, a typical low value for the local power constraint is 0 dBm. A STA that cannot reduce its transmit power to this level or below will not be able to associate to the AP.

The PCP in a PBSS shall advertise both the regulatory maximum transmit power and the local maximum transmit power for its operating channel in Announce and Probe Response frames (using a Country element for the regulatory maximum and a combination of a Country element and a Power Constraint element for the local maximum). In addition, it should advertise both regulatory and local maximum transmit power in DMG Beacon frames.

When dot11SpectrumManagementRequired is false and dot11RadioMeasurementActivated is true, an AP or a PCP may include a Power Constraint element and a Transmit Power Envelope element in Beacon, DMG Beacon, Announce, and Probe Response frames.

11.7.6 Transmit power selection

A STA may select any transmit power for transmissions in a channel within the following constraints:

— A STA shall determine a regulatory maximum transmit power and a local maximum transmit power for a channel in the current regulatory domain before transmitting in the channel.

— An AP shall use a transmit power less than or equal to the regulatory maximum transmit power level for the channel. The AP shall also meet any regulatory mitigation requirement.

— A non-AP STA shall use a transmit power less than or equal to the minimum of the local maximum transmit power level and regulatory client maximum transmit power for the channel.

11.7.7 Transmit power adaptation

A STA may use any criteria, and in particular any path loss and link margin estimates, to dynamically adapt the transmit power for transmissions of an MPDU to another STA. The adaptation methods or criteria are beyond the scope of this standard.

A STA may use a TPC Request frame to request another STA to respond with a TPC Report frame reporting link margin and transmit power information. A STA that receives a TPC Request frame shall respond with a TPC Report frame that contains a TPC Report element in which the Transmit Power field indicates the power used to transmit the response and the Link Margin field indicates the estimated link margin. A DMG STA may also use the link measurement procedure and the DMG Link Margin element to exchange TPC information.

An AP, PCP, or IBSS STA shall autonomously include a TPC Report element with the Link Margin field set to 0 in Beacon frames, DMG Beacon frames, Announce frames, or Probe Response frames.

11.8 DFS procedures

11.8.1 General

Regulations that apply to the 5 GHz band in most regulatory domains require RLANs operating in the 5 GHz band to implement a mechanism to avoid co-channel operation with radar systems and to uniformly utilize available channels. This standard describes such a mechanism, referred to as *dynamic frequency selection (DFS)*.

This subclause describes DFS procedures that can be used to satisfy these and similar future regulatory requirements. The procedures might also satisfy comparable needs in other frequency bands and might be useful for other purposes. For example, some of the procedures described in this subclause could be used for channel selection in a DMG BSS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA shall use the DFS procedures defined in 11.8.1 to 11.8.9 if dot11SpectrumManagementRequired is true.

A STA shall use the DFS procedures defined in 11.8.10 if dot11SpectrumManagementRequired and dot11FutureChannelGuidanceActivated are true.

Attribute dot11SpectrumManagementRequired shall be set to true if regulatory authorities require DFS. It may also be set to true in other circumstances. The DFS procedures provide for the following:

- Associating STAs with an AP based on the STAs' supported channels (see 11.8.2).
- Quieting the current channel so it can be tested for the presence of radar with less interference from other STAs (see 11.8.3).
- Testing channels for radar before using a channel and while operating in a channel (see 11.8.4).
- Discontinuing operations after detecting radar in the current channel to avoid further interference with radar (see 11.8.5).
- Detecting radar in the current and other channels, based on regulatory requirements (see 11.8.6).
- Requesting and reporting measurements in the current and other channels (see 11.8.7).
- Selecting and advertising a new channel to assist the migration of a BSS after radar is detected (see 11.8.8).
- Guiding STAs about the likely future channel should the AP leave this channel (see 11.8.10).

In a DMG BSS, the following DFS procedures apply:

- Associating a STA with an AP or a PCP based on the STA's supported channels (see 11.8.2).
- Quieting the current channel so it can be tested for interference with less interference from associated STAs (see 11.8.3).
- Requesting and reporting measurements in the current and other channels (see 11.8.7).
- Selecting and advertising a new channel to assist the migration of an infrastructure BSS, IBSS, or PBSS (see 11.8.8).

For the purposes of DFS in a non-DMG BSS, the following statements apply:

- A STA with dot11SpectrumManagementRequired true shall not operate in a BSS unless the Spectrum Management bit is 1 in the Capability Information field in Beacon frames and Probe Response frames received from other STAs in the BSS, with the following exception.
  - A STA may operate when the Spectrum Management bit is 0 if the STA determines that it is in a regulatory domain that does not require DFS or determines that it meets regulatory requirements even if DFS is not employed. Potential methods for determining the regulatory domain include receiving a country indication in the Beacon frame, user confirmation, or configuration information within the device. Potential methods to enable regulations to be met even if DFS is not employed include independently detecting radar and ceasing operation on channels on which radar is detected.
- A STA shall set dot11SpectrumManagementRequired to true before associating with an infrastructure BSS, IBSS, or MBSS in which the Spectrum Management bit is 1 in the Capability Information field in Beacon frames and Probe Response frames received from the infrastructure BSS, IBSS, or MBSS.
- An AP may allow association of devices that do not have the Spectrum Management bit equal to 1 in the Capability Information field in Association Request frames and Reassociation Request frames received from a STA to account for the existence of legacy devices that do not support DFS, but do meet regulatory requirements.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.8.2 Association based on supported channels

11.8.2.1 Association based on supported channels in a non-DMG BSS

A STA shall provide an AP with a list of the channels in which the STA can operate when associating or reassociating by including a Supported Channels element in its (Re)Association Request frames.

An AP may use the supported channels list for associated STAs as an input into an algorithm used to select a new channel for the BSS. The specification of this algorithm is beyond the scope of this standard.

An AP may reject an (re)association request from a STA if it considers the STA's supported channel list to be unacceptable. For example, a STA's supported channel list might be unacceptable if it can operate only in a limited number of channels. The criteria for accepting or rejecting (re)associations are beyond the scope of this standard.

11.8.2.2 Providing supported channels upon association in a DMG BSS

An AP or PCP may advertise the regulatory domain in which it is located via a Country element in the DMG Beacon, Announce, or Information Response frames if dot11MultiDomainCapabilityActivated is true.

When it (re)associates, the STA shall provide to the AP or PCP a list of channels in which the STA can operate. The STA does this by including a Supported Channels element in the Information Request or (Re)Association Request frames that it transmits. An AP or PCP can use the supported channels list for associated STAs as an input into an algorithm used to select a new channel for the BSS. The specification of this algorithm is beyond the scope of this standard.

The AP or PCP may advertise the supported channels of associated STAs via an Information Response frame with Subject Address field set to the broadcast address and a Supported Channels element that lists the intersection of channels supported by STAs associated with the BSS, as indicated by their Supported Channels elements.

11.8.3 Quieting channels for testing

When the AP Quiet Mode field of a Quiet Channel element has the value 1, the Quiet Channel element is called a *mode set Quiet Channel element*.

An AP may schedule quiet intervals by transmitting one or more mode set Quiet Channel elements (VHT AP only) and/or one or more Quiet elements in Beacon frames and Probe Response frames.

A mesh STA may schedule quiet intervals by transmitting one or more Quiet elements in Beacon frames and Probe Response frames. A mesh STA shall not transmit mode set Quiet Channel elements.

A non-VHT AP shall not transmit a Quiet Channel element. An AP shall not transmit a Quiet Channel element with the AP Quiet Mode field value equal to 0 in frames that do not include at least one Quiet element. An AP shall not transmit more than one Quiet Channel element with the AP Quiet Mode field equal to 0. An AP shall not transmit a Quiet Channel element if the BSS bandwidth is 20, 40 or 80 MHz.

An AP may stop scheduling quiet intervals, or may transmit Quiet elements with changes in the Quiet Period, Quiet Duration and Quiet Offset fields, or may (VHT AP only) transmit Quiet Channel elements (with changes in the Quiet Period, Quiet Duration and Quiet Offset fields in the case of mode set Quiet Channel elements). A mesh STA may stop scheduling quiet intervals, or may transmit Quiet elements with changes in the Quiet Period, Quiet Duration and Quiet Offset fields, or may transmit (VHT mesh STA only) Quiet Channel elements that are not mode set Quiet Channel elements. Only the most recently received Beacon frame or

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Probe Response frame defines all future quiet intervals; therefore, all schedules for quiet intervals based on older Beacon frames or Probe Response frames shall be discarded.

An AP or PCP in a DMG BSS may measure one or more channels itself, or the AP or PCP may request associated non-AP and non-PCP STAs in the same BSS to measure one or more channels, either in a dedicated measurement interval or during normal operation. The AP or PCP in a DMG BSS may schedule a service period allocated to itself to quiet the associated STAs and use the self-allocated SP for measurement.

An IBSS STA may schedule quiet intervals only if it is the DFS owner. In order to set a quiet interval schedule, the STA transmits one or more Quiet elements in the first Beacon frame establishing the IBSS. All IBSS STAs shall continue these quiet interval schedules by including appropriate Quiet elements in any transmitted Beacon frames or Probe Response frames. An IBSS STA shall not transmit Quiet Channel elements.

NOTE—This means the quiet interval schedules, if any, are defined by the IBSS STA that starts the IBSS. They cannot subsequently be changed, or initiated, by any STA in the IBSS (including the STA that started the BSS and the DFS owner).

Multiple independent quiet intervals may be scheduled, so that not all quiet intervals have the same timing relationship to TBTT, by including multiple Quiet elements or, in an infrastructure BSS, mode set Quiet Channel elements in Beacon frames or Probe Response frames.

Control of the channel is lost at the start of a quiet interval, and the following quieting rules apply:

- The NAV shall be set by a non-VHT STA in the BSS for the length of the quiet interval established by a Quiet element.
- The NAV shall be set by a VHT STA in the BSS for the duration of the quiet interval established by a Quiet element if a Quiet Channel element was not sent or received with the Quiet element.
- A VHT STA in the BSS shall not transmit PPDUs that occupy the secondary 80 MHz channel or, in an infrastructure BSS, transmit PPDUs to the AP during the quiet interval established by a Quiet element if a Quiet Channel element with the AP Quiet Mode field equal to 0 was sent or received with the Quiet element.
- A VHT STA in an infrastructure BSS shall not transmit PPDUs that occupy the secondary 80 MHz channel during the quiet interval established by a Quiet Channel element with the AP Quiet Mode field in the Quiet Channel element equal to 1.
- Transmission by any non-VHT STA in the BSS of any MPDU and any associated acknowledgment within either the primary channel or the secondary channel (if present) shall complete before the start of the quiet interval.
- Transmission by any VHT STA in the BSS of any MPDU and any associated acknowledgment of the BSS shall complete before the start of the quiet interval established by a Quiet element if a Quiet Channel element was not sent or received with the Quiet element.
- Transmission by any VHT STA in the BSS of any PPDUs that occupy the secondary 80 MHz channel or, in an infrastructure BSS, are directed to the AP, and any associated acknowledgment of the BSS, shall complete before the start of the quiet interval established by a Quiet element if a Quiet Channel element with the AP Quiet Mode field equal to 0 was sent or received with the Quiet element.
- Transmission by any VHT STA in the infrastructure BSS of any PPDUs that occupy the secondary 80 MHz channel and any associated acknowledgment of the BSS shall complete before the start of the quiet interval established by a Quiet Channel element with the AP Quiet Mode field in the Quiet Channel element equal to 1.

Before starting transmission of an MPDU, a STA shall check if there is enough time for the exchange to complete within the time allowed by the quieting rules. If there is not enough time, the STA shall defer the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

transmission by selecting a random backoff count, using the present CW (without advancing to the next value in the series). The short retry count and long retry count for the MSDU or A-MSDU are not affected.

11.8.4 Testing channels for radar

A STA does not transmit in a channel unless the channel has been tested for the presence of radar transmissions according to regulatory requirements.

11.8.5 Discontinuing operations after detecting radar

If a STA is operating in a channel and detects radar operating in the channel or accepts that another STA has detected radar operating in the channel, then the STA discontinues transmissions according to regulatory requirements.

11.8.6 Detecting radar

The methods that satisfy regulatory requirements to detect radar transmissions are beyond the scope of this standard.

11.8.7 Requesting and reporting of measurements

The response to a Basic request is a Basic report. A STA in an infrastructure BSS or PBSS shall generate a Basic report in response to a Basic request if the request is received from the AP or PCP with which it is associated, except as specified in this subclause.

A STA may measure one or more channels itself or a STA may request other STAs in the same BSS to measure one or more channels on its behalf. These measurements may occur either during a quiet interval or during normal operation.

In order to request other STAs to measure one or more channels, a STA shall use a Spectrum Measurement Request frame containing one or more Measurement Request elements. The measurement request may be sent to an individual or group destination address. Addressing requests to multiple STAs should be used with care to avoid a reply storm.

The measurement requests effectively allowed by these rules are shown in Table 11-11.

Table 11-11—Allowed measurement requests

Service set	Source of request	Destination of request	Type of measurement request allowed
BSS	AP	STA	Individual or group
	STA	AP	Individual only
	STA	STA	None
IBSS, MBSS	STA	STA	Individual or group
PBSS	PCP	Non-PCP STA	Individual or group
	Non-PCP STA	PCP	Individual
	Non-PCP STA	Non-PCP STA	None

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA that successfully requests another STA to perform a measurement on another channel should not transmit MSDUs, A-MSDUs, or MMPDUs to that STA during the interval defined for the measurement plus any required channel switch intervals. In determining this period, a STA shall assume that any required channel switches take dot11ChannelSwitchTime per switch.

A STA that receives an individually addressed Spectrum Measurement Request frame from a STA in its BSS shall parse the frame's Measurement Request elements in order, with measurements starting at the times specified by the Measurement Request elements.

Any result of a measurement request shall be returned without undue delay to the requesting STA in Measurement Report elements using one or more Spectrum Measurement Report frames. The result may be the completed measurement or an indication that the STA is unable to complete the measurement request.

A STA shall report it is too late to undertake a measurement request if it receives the request after the specified starting time for the measurement.

A STA shall report it is refusing a measurement request if all of the following conditions exist:

— The STA is capable of undertaking a measurement request.
— The STA does not want to undertake the measurement request at this time.
— The measurement request is not mandatory.

NOTE—Measurements are specified as mandatory or optional in 9.4.2.19.

A STA shall report it is incapable of performing a measurement request if any of the following conditions exists:

— The STA is incapable of undertaking an optional measurement request.
— The STA does not support the channel specified in a mandatory measurement request.
— The STA does not support any requested parallel measurements in the same or different channels.

A Spectrum Measurement Report frame shall contain the same value in its Dialog Token field as the Dialog Token field in the corresponding Spectrum Measurement Request frame, and each Measurement Report element shall contain the same value in its Measurement Token field as the Measurement Token field in the corresponding Measurement Request element.

A STA may autonomously report measurements to another STA in its BSS by transmitting a Spectrum Measurement Report frame that includes a Dialog Token field set to 0 and one or more Measurement Report elements. An IBSS STA may also autonomously report measurements to other STAs in the IBSS using the Channel Map field in the IBSS DFS element in a Beacon frame or Probe Response frame.

A STA may enable or disable measurement requests or autonomous measurement reports from another STA by transmitting Measurement Request elements with the Enable subfield set to 1 and the Request subfield and Report subfield set to 0 or 1, as appropriate. These elements do not require a corresponding Measurement Report element in a Spectrum Measurement Report frame. All measurement requests and reports shall be enabled by default. An AP or PCP may ignore a request to disable a mandatory measurement request. All other such requests shall be honored.

The measurement request and report procedures are defined in 11.10.

11.8.8 Selecting and advertising a new channel

11.8.8.1 General

A channel switch is an attempt to move a BSS to a new operating channel. It is an objective that disruption to the BSS be minimized in this process, although it should be recognized that a channel switch might not successfully move all STAs.

Two procedures are defined for switching channels: the channel switching procedure, which is defined in 11.8.8 and 11.8.9, and the extended channel switching procedure, which is defined in 11.9.

It should also be stressed that both the channel switching procedure and the extended channel switching procedure are distinct from the regulatory requirement to cease transmission on a particular channel in the presence of radar.

The Address 1 field of a Channel Switch Announcement frame shall be set to the broadcast address.

After moving into a new operating channel, a STA shall perform CCA until a frame is detected by which it can set its NAV, or until a period of time indicated by the NAVSyncDelay parameter from the most recent MLME-START.request or MLME-JOIN.request primitive has transpired.

NOTE—Only the extended channel switching procedure allows switching to a different operating class, and hence switching to a different band.

11.8.8.2 Selecting and advertising a new channel in a non-DMG infrastructure BSS

This subclause describes operation in an infrastructure BSS that is a non-DMG BSS. For a DMG infrastructure BSS, see 11.8.8.6.

The decision to switch to a new operating channel in an infrastructure BSS shall be made only by the AP. An AP may make use of the information in Supported Channels elements and the results of measurements undertaken by the AP and other STAs in the BSS to assist the selection of the new channel. The algorithm to choose a new channel is beyond the scope of this standard. The AP shall attempt to select a new channel that is supported by all associated STAs.

An AP shall inform associated STAs that the AP is moving to a new channel and shall maintain the association by advertising the switch using Channel Switch Announcement elements in Beacon frames, Probe Response frames, and Channel Switch Announcement frames until the intended channel switch time. The AP may force STAs in the BSS to stop transmissions until the channel switch takes place by setting the Channel Switch Mode field in the Channel Switch Announcement element to 1. The channel switch should be scheduled so that all STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Channel Switch Announcement element before the switch. The AP may send the Channel Switch Announcement frame in a BSS without performing a backoff, after determining the WM is idle for one PIFS (see 10.3.2.3).

When an AP transmits an Extended Channel Switch Announcement frame or a frame containing a Channel Switch Announcement element or an Extended Channel Switch Announcement element, it should include a Max Channel Switch Time element in the frame if the Channel Switch Count field is nonzero and it may include the element if the field is 0. When the AP includes the Max Channel Switch Time element, the AP shall transmit the first Beacon frame in the new channel no later than the time indicated in the Switch Time field of the Max Channel Switch Time element after the last Beacon frame transmitted in the current channel, unless the AP determines that it is unable to operate on the new channel.

NOTE 1—An Extended Channel Switch Announcement frame does not contain an Extended Channel Switch Announcement element (see 9.6.7.7).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If a Channel Switch Announcement element in a Beacon or Probe Response frame is used to announce a switch to a 20 MHz BSS bandwidth, then a Wide Bandwidth Channel Switch subelement in a Channel Switch Wrapper element shall not be present in the same frame.

If a Channel Switch Announcement element in a Beacon or Probe Response frame is used to announce a switch to a 40 MHz BSS bandwidth, then a Wide Bandwidth Channel Switch subelement in a Channel Switch Wrapper element shall also be present in the same frame if the STA sending the frame is extended spectrum management capable.

A Channel Switch Wrapper element shall not be included in Beacons and Probe Response frames if the element contains zero subelements.

A STA that receives a Channel Switch Announcement element may choose not to perform the specified switch, but to take alternative action. A STA that receives a Max Channel Switch Time element from its associated AP should not transmit a frame to the AP on the new channel until it receives a frame on the new channel from the AP.

NOTE 2—Whether or not a Max Channel Switch Time element is included, regulations might forbid a STA from transmitting on the new channel until it receives an enabling signal (e.g., a Beacon frame).

NOTE 3—As an alternative to performing the specified channel switch, a STA might choose to move to a different BSS.

An AP that has indicated OCVC shall deauthenticate non-AP STAs that have indicated OCVC, are not in WNM Sleep, and have failed to send an SA Query Request frame within an implementation specific timeout following a channel switch, and should pause the transmission and reception of Data frames until the SA query procedure has completed successfully for additional protection.

If dot11RSNAOperatingChannelValidationActivated is true and a channel switch is requested while the handshake is in progress, the handshake should be aborted.

A non-AP STA in an infrastructure BSS shall not transmit the Channel Switch Announcement element.

11.8.8.3 Selecting and advertising a new channel in an IBSS

DFS in an IBSS is complicated by the following:

- There is no central AP function for collating measurements or coordinating a channel switch. If STAs make independent decisions to switch channel in the presence of radar, there is a danger that all STAs announce switches to different channels if several of them detect the radar.
- There is no association protocol that can be used to
  - Exchange supported channel information
  - Determine membership of the IBSS at a given instant for requesting measurements.
- Beaconing is a shared process; therefore, there is no guarantee that a STA that has something to send (e.g., a channel switch message) will be the next STA to transmit a Beacon frame.
- A 20/40 MHz IBSS cannot be changed to a 20 MHz IBSS, and a 20 MHz IBSS cannot be changed to a 20/40 MHz IBSS.

The DFS owner service, IBSS DFS element, and Channel Switch Announcement frame address these complications:

- The DFS owner service provides a central point of coordination for a channel switch. It attempts to minimize the probability that multiple STAs concurrently decide to switch to different channels. The DFS Owner field and DFS Recovery Interval field in the IBSS DFS element support the DFS owner service.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— Each STA shall include a Channel Map field in the IBSS DFS elements that it transmits. The channel map communicates the STA-supported channel set and basic measurement reports for that STA.
— Each STA shall have the ability to send a Channel Switch Announcement element in a Management frame other than a Beacon frame or Probe Response frame.

The potential for hidden nodes within an IBSS means that an IBSS channel switching procedure might not move all STAs. In some regulatory domains, each STA in an IBSS is required by regulation to detect radar and cease transmission, after a required interval, on any channel on which the presence of radar is detected.

A STA at which an IBSS is started shall be a DFS owner in that IBSS. That STA shall include its MAC address in the DFS Owner field of the IBSS DFS element and DFS Recovery Interval field from the MLME.START.request primitive parameter. The purpose of the DFS owner is to coordinate a channel switch. All STAs in an IBSS shall have the ability to become DFS owner.

Each IBSS STA shall adopt the DFS Owner field and the DFS Recovery Interval field from any valid IBSS DFS element when the received frame contains a matching SSID and the value of the timestamp is later than the STA's TSF timer. The STA shall include the adopted values in the IBSS DFS elements it transmits. Because all IBSS STAs participate in sending Beacon frames, this process always, over a number of beacon intervals, results in a unified view of one DFS owner throughout the IBSS.

In order to attempt a channel switch using the DFS owner, a STA that detects radar shall broadcast one or more Spectrum Measurement Report frames indicating the presence of the radar.

A DFS owner receiving a Spectrum Measurement Report frame indicating the presence of radar in the current channel shall select and advertise a new operating channel (including the possibility of no change). The DFS owner may make use of information received in Channel Map fields and from measurements undertaken by other members of the IBSS to assist the selection of the new channel. The algorithm to choose a new channel is beyond the scope of this standard, but shall satisfy any regulatory requirements, including uniform spreading rules and channel testing rules. The DFS owner shall attempt to select a new channel that is supported by all members of the IBSS. Note that this process might be imperfect in that the DFS owner might have incomplete knowledge and there might not be a suitable channel.

The DFS owner shall attempt to make the members of the IBSS aware of the new operating channel by broadcasting at least one Channel Switch Announcement frame. The DFS owner may transmit the Channel Switch Announcement frame in an IBSS without performing a backoff, after determining that the WM is idle for one PIFS (see 10.3.2.3). The DFS owner shall also include the Channel Switch Announcement element in all Beacon frames, Probe Response frames, or Channel Switch Announcement frames until the intended channel switch time. A STA that receives a valid Channel Switch Announcement element that is not a superseded Channel Switch Announcement element (see 11.15.3.3) shall repeat this element in all Beacon frames and Probe Response frames that it transmits. The DFS owner may attempt to silence STAs in the IBSS until the channel switch takes place using the Channel Switch Mode field in the Channel Switch Announcement element. If possible, the channel switch should be scheduled so that all STAs in the IBSS, including STAs in power save mode, have the opportunity to receive at least one Channel Switch Announcement element before the switch.

If a STA does not receive a valid Channel Switch Announcement element from the DFS owner within the DFS recovery time, then it shall enter DFS recovery mode. DFS recovery time is measured from the end of the frame that first announced radar presence, whether that frame was transmitted by the STA or received from another STA. In DFS recovery mode the STA shall assume the role of DFS owner, shall select a new operating channel, and shall advertise the new channel by transmitting a Channel Switch Announcement frame using the contention resolution algorithm defined for beacon transmission at TBTT in 11.1.3.5. The STA shall also

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

include the Channel Switch Announcement element in all Beacon frames and Probe Response frames until the intended channel switch time. A STA that is not the DFS owner shall not initiate a channel switch.

If the STA receives a valid Channel Switch Announcement element that is not a superseded Channel Switch Announcement element (see 11.15.3.3) from another member of the IBSS, the STA shall leave DFS owner recovery mode prior to the channel switch and adopt the received channel switch information. If the Channel Switch Announcement element was in a Beacon frame or Probe Response frame, the STA shall also adopt the STA identified by the DFS owner address of the IBSS DFS element as the DFS owner. If the Channel Switch Announcement element was in a Channel Switch Announcement frame, the receiving STA shall adopt the STA that transmitted the frame as the DFS owner.

There are several circumstances when DFS owner recovery is needed (e.g., if the original DFS owner has left the network or if the original measurement report was not received by the initial DFS owner). Note that DFS owner recovery might temporarily give rise to more than one DFS owner in the IBSS. This risk is mitigated by the random nature of the IBSS DFS recovery mechanism. However, because all IBSS STAs participate in sending Beacon frames, over a number of beacon periods, there will be convergence from multiple DFS owners to one DFS owner.

11.8.8.4 MBSS channel switching

11.8.8.4.1 General

A mesh channel switch might be triggered by the need to avoid interference to a detected radar signal, or to reassign mesh STA channels to maintain MBSS connectivity.

A mesh STA may make use of the information in Supported Channels elements, Supported Operating Classes elements, and the results of measurements undertaken by the mesh STAs in the MBSS to assist the selection of the new channel. The algorithm for choosing a new channel is beyond the scope of this standard.

A 20/40 MHz MBSS may be changed to a 20 MHz MBSS and a 20 MHz MBSS may be changed to a 20/40 MHz MBSS.

When an MBSS switches from a 20 MHz MBSS to a 20/40 MHz MBSS or switches from a 20/40 MHz MBSS to a 20 MHz MBSS, a mesh STA might need to do path maintenance to find an optimized path.

11.8.8.4.2 Initiating MBSS channel switch

A mesh STA shall not initiate a new channel switch attempt if there is an ongoing channel switch attempt by this mesh STA.

A mesh STA shall inform each of the peer mesh STAs that the mesh STA is moving to a new channel while maintaining mesh peerings by including Channel Switch Announcement elements together with the Mesh Channel Switch Parameters element in all Beacon frames, Probe Response frames, and Channel Switch Announcement frames that it transmits until the intended channel switch time. The channel switch should be scheduled so that all mesh STAs in the MBSS, including mesh STAs in power save mode, have the opportunity to receive at least one Channel Switch Announcement element before the switch.

The fields in the Channel Switch Announcement element are set as follows:

— The Channel Switch Count field shall be set to the time period until the mesh STA sending the Channel Switch Announcement element switches to the new channel.
— The Channel Switch Mode field is reserved.
— The New Channel Number field shall be set to the number of the channel to which the mesh STA is moving.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The fields in the Mesh Channel Switch Parameters element are set as follows:

— The Precedence Value field shall be set to a random value selected from a uniform distribution in the range 0 to 65 535.

— The mesh STA may force mesh STAs in the MBSS to stop transmissions of frames (except frames containing Channel Switch Announcement element) until the channel switch takes place by setting the Transmit Restrict subfield of the Flags field to 1.

— The Reason subfield in the Flags field shall be set to 1 to indicate that the content of the Reason Code field (as defined in Table 9-79) is valid. The Reason Code field shall be set to MESH-CHANNEL-SWITCH-REGULATORY-REQUIREMENTS when the channel switch is initiated to meet regulatory requirement; otherwise, the Reason Code field shall be set to MESH-CHANNEL-SWITCH-UNSPECIFIED.

— The Initiator subfield of the Flag field shall be set to 1.

— The Time To Live field should be set to the maximum number of hops (e.g., dot11MeshHWMPnetDiameter) for which this Channel Switch attempt is intended.

11.8.8.4.3 Processing channel switch announcement

Upon receipt of a Channel Switch Announcement frame or Extended Channel Switch Announcement frame, a mesh STA shall not accept and shall not process the received Channel Switch Announcement element or Extended Channel Switch Announcement element, if any of the following is true:

— The Mesh Channel Switch Parameters element is not present in the received frame containing the Channel Switch Announcement element or the Extended Channel Switch Announcement element.

— The Time To Live field in the received Mesh Channel Switch Parameters element is 0.

— A mesh channel switch is already running and the mesh STA has not yet moved into the new channel and/or operating class and the current precedence value is greater than or equal to the received Precedence Value field.

A mesh STA that receives a Channel Switch Announcement element may choose not to perform the specified switch, but to take alternative action. For example, it may choose to move to a different MBSS.

If dot11RSNAOperatingChannelValidationActivated is true and a channel switch is requested while the handshake is in progress, the handshake should be aborted.

When a mesh STA accepts a channel switch, it shall adopt the information received in the Channel Switch Announcement element and the Mesh Channel Switch Parameters element. The mesh STA shall schedule the channel switch according to this information. If the Time To Live field value in the received Mesh Channel Switch Parameters element is greater than 1, the mesh STA shall transmit a Channel Switch Announcement frame and shall include a Channel Switch Announcement element together with a Mesh Channel Switch Parameters element in the Beacon and Probe Response frames until the intended channel switch time. The Channel Switch Mode and New Channel Number fields in the transmitted Channel Switch Announcement element(s) are set to the same values as in the received Channel Switch Announcement element. The Channel Switch Count field is set to indicate the time remaining until the channel switch, as specified in 9.4.2.17. The Reason Code and Precedence Value fields in the transmitted Mesh Channel Switch Parameters element(s) are set to the same values as in the received Mesh Channel Switch Parameters element. The Time to Live and Flags fields are set as specified in 9.4.2.101. The Time To Live field shall be set to the received Time To Live field minus 1. The Initiator field shall be set to 0. The Transmit Restrict field shall be set to 1 when the mesh STA requires neighboring mesh STAs not to transmit (until the scheduled channel switch occurs) further frames that do not contain the Channel Switch Announcement element on the current channel. The Transmit Restrict subfield shall be set to 0 otherwise.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

It is possible that a channel switch is not successful in moving all of the mesh STAs in MBSS to the new operating channel. Transitioning to a new channel does not tear down mesh peerings and, as long as the mesh peers move to the new operating channel, their peerings are maintained in the new channel.

After moving into a new operating channel, the mesh STA shall perform CCA until a frame is detected by which it can set its NAV, or until a period of time indicated by the NAVSyncDelay parameter from the most recent MLME-START.request primitive has transpired.

11.8.8.4.4 Channel switch across an operating class

When dot11OperatingClassesImplemented is true and the mesh STA is capable of operation in more than one operating class, the mesh STA shall include the Supported Operating Classes element within its Mesh Peering Open frames. The Supported Operating Classes element announces the operating classes that the mesh STA supports.

When dot11OperatingClassesImplemented is true, a mesh STA may switch from the operating channel to a channel in a different operating class using an Extended Channel Switch Announcement element or frame.

NOTE —A mesh STA can switch from the operating channel to a channel in the same operating class using a Channel Switch Announcement or Extended Channel Switch Announcement element or frame (see 11.9.3.4).

11.8.8.5 HT-greenfield transmissions in operating classes that include a behavior limit of DFS_50_100_Behavior

The requirements described in this subclause apply only when an HT STA is operating in an operating class for which the behavior limits set listed in Annex E includes the value DFS_50_100_Behavior; i.e., the operating class is subject to DFS with 50–100 μs radar pulses.

A non-HT OBSS scan operation is a passive or active scan of the primary channel and of the secondary channel if the STA conducting the scan is in a 20/40 MHz BSS that the STA currently uses or intends to use. During a non-HT OBSS scan operation, the channel scan duration shall be a minimum of dot11OBSSScanPassiveTotalPerChannel TUs when scanning passively and a minimum of dot11OBSSScanActiveTotalPerChannel TUs when scanning actively.

Before an HT STA starts a BSS with the OBSS Non-HT STAs Present field of the HT Operation element equal to 0, the HT STA shall perform a non-HT OBSS scan in order to search for any existing non-HT OBSSs.

When an HT STA detects that there are one or more non-HT OBSSs, and if the HT STA starts a BSS on that channel, then the HT STA shall set to 1 the OBSS Non-HT STAs Present field of the HT Operation element it transmits; otherwise, the HT STA may set to 0 the OBSS Non-HT STAs Present field of the HT Operation element it transmits.

NOTE 1—Detection of a non-HT OBSS can be achieved by the reception of a Beacon or Probe Response frame that does not contain an HT Capabilities element or HT Operation element.

An HT AP shall not transmit a PPDU with the FORMAT parameter of the TXVECTOR set to HT_GF if the OBSS Non-HT STAs Present field of the HT Operation element is equal to 1 in the most recently transmitted Management frame that contained that element.

An HT non-AP STA shall not transmit a PPDU with the FORMAT parameter of the TXVECTOR set to HT_GF if the most recent frame received from its AP containing an HT Operation element has the OBSS Non-HT STAs Present field equal to 1.

NOTE 2—This requirement applies also to PPDUs transmitted on a direct link between two non-AP STAs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When moving the BSS to a new channel or set of channels and before completing a non-HT OBSS scan of the new channel or set of channels, an HT AP shall set to 1 the OBSS Non-HT STAs Present field of the HT Operation element it transmits. After the HT AP completes one non-HT OBSS scan of the new channel or set of channels and if the HT AP has detected that there are zero non-HT OBSSs, then the HT AP may set to 0 the OBSS Non-HT STAs Present field of the HT Operation element it transmits.

11.8.8.6 Selecting and advertising a new channel in a DMG BSS

The decision to switch to a new operating channel in a DMG BSS shall be made only by an AP or PCP. An AP or PCP may make use of the information in received Supported Channels elements and the results of measurements undertaken by the AP or PCP and other STAs in the BSS to assist the selection of the new channel. The algorithm to choose a new channel is beyond the scope of this standard.

An AP or PCP shall inform associated STAs that the AP or PCP is changing to a new channel and shall maintain the association by advertising the switch using the Extended Channel Switch Announcement element in its transmitted DMG Beacon frames, Announce frames, and Information Response frames until the intended channel switch time. The channel switch should be scheduled so that all non-AP and non-PCP STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Extended Channel Switch Announcement element before the switch. A STA may ignore the Channel Switch Mode field and either cease transmissions or attempt new transmissions in the operating channel until the channel change occurs.

A STA that receives an Extended Channel Switch Announcement element may choose not to perform the specified switch, but to take alternative action. For example, it may choose to move to a different BSS. A non-AP and non-PCP STA in an infrastructure BSS or PBSS shall not transmit the Extended Channel Switch Announcement element.

11.8.8.7 Selecting and advertising new channels in an EDMG BSS

A change in the BSS operating channels or operating channel width as announced by the EDMG Operation element is referred to as a change of operating channels.

The decision to switch to new operating channels in an EDMG BSS shall be made only by an AP or PCP. An AP or PCP may make use of the information it received in EDMG Capabilities elements and the results of measurements undertaken by the AP or PCP and other STAs in the BSS to assist the selection of the new operating channels. The algorithm to choose the new operating channels is beyond the scope of this standard.

An AP or PCP shall inform associated STAs that the AP or PCP is changing operating channels and shall maintain the association by advertising the switch using the Extended Channel Switch Announcement element and EDMG Wide Bandwidth Channel Switch element in its transmitted DMG Beacon frames, Announce frames, or Information Response frames until the intended channel switch time. The channel switch should be scheduled so that all non-AP and non-PCP STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Extended Channel Switch Announcement element and EDMG Wide Bandwidth Channel Switch element before the switch. A STA may ignore the Channel Switch Mode field and either cease transmissions or attempt new transmission in the operating channel until the channel change occurs.

A STA that receives an Extended Channel Switch Announcement element and EDMG Wide Bandwidth Channel Switch element chooses whether to perform the specified switch. If a STA that receives an Extended Channel Switch Announcement element and EDMG Wide Bandwidth Channel Switch element chooses to perform the specified switch, it shall operate on the channels indicated in the EDMG Wide Bandwidth Channel Switch element. If a STA that receives an Extended Channel Switch Announcement

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

element and an EDMG Wide Bandwidth Channel Switch element chooses not to perform the specified switch, it may take alternative action. For example, it may choose to move to a different BSS.

A non-AP and non-PCP STA in an infrastructure BSS or PBSS shall not transmit the Extended Channel Switch Announcement element or the EDMG Wide Bandwidth Channel Switch element.

11.8.9 Channel Switch Announcement element operation

If a non-DMG STA in a BSS that is not an IBSS receives a Channel Switch Mode field that has the value 1, it shall not transmit any more frames on the channel until the scheduled channel switch occurs. An IBSS STA may treat a Channel Switch Mode field equal to 1 as advisory. A Channel Switch Mode equal to 0 does not impose any requirement on the STA that receives the Channel Switch Announcement frame.

NOTE —A channel switch announcement cannot be used to switch bands, since the operating class is not communicated.

11.8.10 Future Channel Guidance operation

This subclause defines a mechanism to create, communicate and act on the Future Channel Guidance element.

When dot11FutureChannelGuidanceActivated is true, a STA shall follow these procedures for future channel guidance operation.

A STA transmitting Beacon frames transmits the Future Channel Guidance element in (Re)Association Response frames and optionally in Beacon frames.

In some bands, the channel clearing time will be much less than one second for all STAs, and future channel guidance permits all STAs to know what channels will be used if the current channels are cleared.

In some bands, Beacon frames are an enabling signal, and some STAs are not allowed to transmit in the band before receiving an enabling signal. When Beacon frame reception stops, some STAs are no longer enabled to transmit in the band. In these bands, when Beacon frame reception stops, it is an implicit message to switch from current channels to other channels according to prior future channel guidance.

Future channel guidance indicates future channels that the Beaconing STA switches to while maintaining associations and mesh peering relationships (see 11.8.8.2, 11.8.8.3, 11.8.8.4.2, 11.8.8.6, 11.9.3.2, 11.9.3.3, and 11.9.3.4).

A STA receiving the Future Channel Guidance element shall retain the information until it receives a different Future Channel Guidance element from the same STA, it receives a Channel Switch Announcement element or a Channel Switch Announcement frame from the same STA, or it chooses alternative action. For example, it may choose to move to a different BSS.

11.9 Extended channel switching (ECS)

11.9.1 General

This subclause describes ECS procedures that change the BSS operating channel frequency and bandwidth. When the STA’s dot11ExtendedChannelSwitchActivated value is true, the enabling STAs (see 11.11), APs, DFS owners, and mesh STAs may construct and transmit frames that contain Extended Channel Switch Announcement elements.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA shall use the ECS procedures defined in this subclause if dot11ExtendedChannelSwitchActivated is true. To indicate that it can perform ECS procedures, a STA shall set dot11ExtendedChannelSwitchActivated, dot11MultiDomainCapabilityActivated and dot11OperatingClassesRequired to true and shall set to 1 the Extended Channel Switching field in the Extended Capabilities elements it transmits. When dot11ExtendedChannelSwitchActivated is false, the STA shall not use ECS procedures. When an AP is switching to a different channel and one or more of its associated STAs do not support extended channel switching capability, then both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames may be used.

If dot11ExtendedChannelSwitchActivated and dot11LCIDSERequired are true, frames containing Channel Switch Announcement elements shall not be transmitted.

An enabling STA may send frames containing Extended Channel Switch Announcement elements to dependent STAs (see 11.11.5). If dot11DSERequired is true, a STA shall perform ECS procedures to switch at the time indicated by the channel switch count, or the STA shall change its enablement state for the enabling STA to unenabled.

The Address 1 field of an Extended Channel Switch Announcement frame shall be set to the broadcast address.

After moving into a new operating channel, a STA shall perform CCA until a frame is detected by which it can set its NAV, or until a period of time indicated by the NAVSyncDelay parameter from the most recent MLME-START.request or MLME-JOIN.request primitive has transpired.

NOTE—The RSN configuration does not change across a channel switch. This means, for example, that a switch from the 2.4 GHz or 5 GHz band to the 6 GHz band is only possible if the RSNE and RSNXE advertised in the 2.4 GHz or 5 GHz band are also valid in the 6 GHz band.

11.9.2 Advertising supported operating classes

When dot11ExtendedChannelSwitchActivated or dot11OperatingClassesRequired is true, the Current Operating Class field in the Supported Operating Classes element shall indicate the operating class in use for transmission and reception. The Operating Classes field shall list all operating classes with which the STA is capable of operating for the country that is specified in the Country element (9.4.2.7).

11.9.3 Selecting and advertising a new channel and/or operating class

11.9.3.1 General

An attempt may be made to move a BSS to a new operating channel and/or new operating class using extended channel switching. An objective during this process is to minimize disruption to the BSS. It is possible, however, that an extended channel switch is not successful in moving all STAs to the new channel and/or operating class.

11.9.3.2 Selecting and advertising a new channel in an infrastructure BSS

When an AP with dot11DSERequired true receives frames containing Extended Channel Switch Announcement elements from the enabling STA, it shall advertise an extended channel switch with the same channel switch mode, new operating class, new channel number, and channel switch count as received in the Extended Channel Switch Announcement elements.

The decision to switch to a new operating channel and/or operating class in an infrastructure BSS is made by the AP when dot11DSERequired is false. An AP may make use of the information in the Supported Channels element, Supported Operating Classes element, and the results of measurements undertaken by the AP and

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

other STAs in the BSS to assist the selection of the new channel and/or operating class. A method to make the decision and to select a new channel is defined in 11.8.8.2.

When an AP is switching to a different operating class and dot11ExtendedChannelSwitchActivated is true, then the AP shall use the Extended Channel Switch Announcement element and frame. In addition, the AP may also send Channel Switch Announcement elements and frames when the requirements signified by the new operating class are met by all associated STAs.

When an AP is switching to a new channel within the same operating class and dot11ExtendedChannelSwitchActivated is true, then the AP shall send the Extended Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames. If dot11ExtendedChannelSwitchActivated is false, the AP shall send the Channel Switch Announcement element and frame.

When dot11ExtendedChannelSwitchActivated is true, an AP shall inform associated STAs that the AP is moving to a new channel and/or operating class and maintain the association by advertising the switch using Extended Channel Switch Announcement elements in any transmitted Beacon frames, Probe Response frames, and Extended Channel Switch Announcement frames until the intended channel switch time. The AP may request STAs in the BSS to stop transmissions until the channel switch takes place by setting the Extended Channel Switch Mode field to 1 in the Extended Channel Switch Announcement element. If possible, the channel switch should be scheduled so that all STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Extended Channel Switch Announcement element before the switch. The AP may send the Extended Channel Switch Announcement frame without performing a backoff, after determining the WM is idle for one PIFS (see 10.3.2.3). When both the Extended Channel Switch Announcement and the Channel Switch Announcement elements are transmitted in Action frames, they shall be sent in separate frames.

When an AP transmits an Extended Channel Switch Announcement frame or a frame containing a Channel Switch Announcement element or an Extended Channel Switch Announcement element, it should include a Max Channel Switch Time element in the frame if the Channel Switch Count field is nonzero and it may include the element if the field is 0. When the AP includes the Max Channel Switch Time element, the AP shall transmit the first Beacon frame in the new channel no later than the time indicated in the Switch Time field of the Max Channel Switch Time element after the last Beacon frame transmitted in the current channel, unless the AP determines that it is unable to operate on the new channel.

If an Extended Channel Switch Announcement element in a Beacon or Probe Response frame is used to announce a switch to a 40 MHz BSS bandwidth, then a Wide Bandwidth Channel Switch subelement in a Channel Switch Wrapper element may be present in the same frame if the STA sending the frame is extended spectrum management capable.

When a STA with dot11DSERequired equal to false receives an Extended Channel Switch Announcement element, it may choose not to perform the specified switch, but to take alternative action. A STA that receives a Max Channel Switch Time element from its associated AP should not transmit a frame to the AP on the new channel until it receives a frame on the new channel from the AP.

NOTE 1—Whether or not a Max Channel Switch Time element is included, regulations in certain regulatory domains might forbid a STA from transmitting on a new channel until it has received an enabling signal (e.g., a Beacon frame).

NOTE 2—As an alternative to performing the specified channel switch, a STA might choose to move to a different BSS.

If dot11RSNAOperatingChannelValidationActivated is true and a channel switch is requested while a security handshake is in progress, the handshake should be aborted.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the STA chooses to perform the specified switch and dot11RSNAOperatingChannelValidationActivated is true and the AP has indicated OCVC, after switching to the new channel the STA shall wait a random delay uniformly-distributed in the range between 0 and 5000 μs, and then initiate the SA query procedure once any applicable conditions for transmitting on the new channel are met (e.g., channel access procedures, DFS or enablement procedures). This procedure shall be initiated whether or not the switch was based on a protected Management frame that contained the new operating channel information. The STA may pause Data frame transmission and may discard any received Data frames until the SA query procedure has completed successfully for additional protection.

If a STA initiates SA query procedure to validate a channel switch, any existing SA query procedure for channel switch validation shall be abandoned.

A non-AP STA in an infrastructure BSS shall not transmit the Extended Channel Switch Announcement element.

11.9.3.3 Selecting and advertising a new channel in an IBSS

When a DFS owner with dot11DSERequired true receives frames containing Extended Channel Switch Announcement elements from the enabling STA, it shall advertise an extended channel switch with the same channel switch mode, new operating class, new channel number, and channel switch count as received in the Extended Channel Switch Announcement elements.

The DFS owner that advertises a channel switch shall follow the rules defined in 11.8.8.3 with the following extensions:

a) If a DFS owner is switching to a new channel or to the same channel in a different operating class and dot11ExtendedChannelSwitchActivated is true, then the DFS owner shall use the Extended Channel Switch Announcement element and frame.
b) If a DFS owner is switching to a new channel within the same operating class and dot11ExtendedChannelSwitchActivated is true, then the DFS owner shall send the Extended Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames. If dot11ExtendedChannelSwitchActivated is false, the DFS owner shall send the Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames.
c) If both the Extended Channel Switch Announcement and the Channel Switch Announcement elements are transmitted in Public Action frames, they shall be sent in separate frames.

The DFS owner may transmit the Extended Channel Switch Announcement frame in an IBSS without performing a backoff, after determining that the WM is idle for one PIFS (see 10.3.2.3).

11.9.3.4 Selecting and advertising a new channel in an MBSS

A mesh STA may make use of the information in the Supported Channels element, Supported Operating Classes element, and the results of measurements undertaken by this mesh STA and other mesh STAs in the MBSS to assist the selection of the new channel and/or operating class.

If dot11ExtendedChannelSwitchActivated is true, the mesh STA that advertises a channel switch shall follow the rules defined in 11.8.8.4 with the following extensions:

a) If a mesh STA is switching to a different operating class, then the mesh STA shall use the Extended Channel Switch Announcement element and frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

b) If a mesh STA is switching to a new channel within the same operating class, then the mesh STA shall send the Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames.

c) The Channel Switch Announcement element and Extended Channel Switch Announcement element, when sent, shall be included in the Beacon and Probe Response frames until the intended channel switch time.

11.10 Radio measurement procedures

11.10.1 General

This subclause describes the radio measurements and the procedures for requesting and reporting radio measurements between STAs. When a STA implements support for one or more of the procedures described in this subclause, it shall set dot11RadioMeasurementActivated to true. When dot11RadioMeasurementActivated is true, dot11MultiDomainCapabilityImplemented, dot11MultiDomainCapabilityActivated, dot11OperatingClassesImplemented, and dot11OperatingClassesRequired shall be true.

NOTE—A key issue in radio measurement is network operation and management, considering each STA's service load, power state, and operating conditions. Timely measurement reports might be more important than percentage of wireless capacity or STA capacity used by radio measurements. The measurement requester might consider traffic load and application requirements, regulatory requirements, and specific measurement states from every STA in support of wireless network management. There are no typical scenarios that describe IEEE 802.11 operation in all bands. Off-channel measurements are desirable to gather timely information about the channel to which to switch BSS operation, and the noisier the operating environment, the more urgent the need for radio measurements off the serving channel. In any case, the measuring STA might refuse any measurement request.

11.10.2 Measurement on operating and nonoperating channels

Measurements on nonoperating channels might need the measuring STA to interrupt its data services on the operating channel, switch channels, and make measurements. Measurements on the operating channel might not require the STA to interrupt its data services.

All stations are responsible for maintaining data services and an association or membership with the BSS on the operating channel while performing measurements on nonoperating channels.

A STA shall determine the time between successive nonoperating channel measurements. This time may be a fixed length, or it may be determined by the STA using application-specific (or other) knowledge.

11.10.3 Measurement start time

A Radio Measurement Request frame may contain a single Measurement Request element or a sequence of Measurement Request elements. A STA that accepts the first or only measurement request within a Radio Measurement Request frame shall start the measurement as soon as practical after receiving the request. Subsequent measurement requests in the Radio Measurement Request frame that are accepted shall start as soon as practical after processing the previous request in the frame. Such measurement start times shall be subject to any specified randomization interval.

The radio measurement category permits a randomization interval to be specified for measurement start times. The intent of this is to avoid traffic storms that could arise with synchronized group addressed measurements. Prior to making each measurement in the requested sequence, the STA shall calculate a random delay distributed uniformly in the range 0 to the randomization interval specified in the measurement request. The STA shall not start the measurement until this delay has expired. Randomization interval is specified in units of TUs. A randomization interval field value of 0 in a measurement request indicates that no random delay is to be used.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE—It is important that designers recognize the need for statistical independence of the random number streams between STAs.

A number of repetitions may be specified in the Radio Measurement Request frame. In this case, the measurements in the frame are repeated as detailed further in 11.10.7. Each time a measurement is repeated, the STA shall recalculate the random delay as described above.

When a Measurement Start Time field is present in a measurement report, the measuring STA shall report the value of its TSF timer at the time the measurement started to an accuracy of ± 1 TU.

11.10.4 Measurement duration

The values of Request Measurement Duration and Duration Mandatory in the received measurement request and the dot11RMMaxMeasurementDuration setting in the receiving STA determine if the receiving STA accepts the measurement request and for how long the measurement is performed. dot11RMMaxMeasurementDuration indicates a measurement duration using the following formula:

$$\text{Maximum Measurement Duration in TUs} = 2^{(\text{dot11RMMaxMeasurementDuration} - 4)} \times \text{BeaconInterval}$$

Table 11-12 describes how a STA responds to a measurement request depending on the values of dot11RMMaxMeasurementDuration, Measurement Duration, and Duration Mandatory.

Table 11-12—Measurement Duration

dot11RMMaxMeasurementDuration	Measurement Duration in the Measurement Request	Duration Mandatory	Notes
0	Any value	1	The STA shall perform measurements for the requested measurement duration.
0	Any value	0	The STA may perform measurements for a duration shorter than the requested measurement duration.
Nonzero	Any value	0	The STA shall perform measurements for a maximum duration that is equal to the minimum of the requested measurement duration and the dot11RMMaxMeasurementDuration.
Nonzero	Requested measurement duration > Maximum Measurement Duration in TUs	1	The STA shall reject the measurement request with the Measurement Report Mode set to “refused.”
Nonzero	Requested measurement duration ≤ Maximum Measurement Duration in TUs	1	The STA shall perform the measurement for the requested duration.

Measurement duration on nonoperating channels is defined by dot11RMNonOperatingChannelMaxMeasurementDuration. If this attribute is 0, the STA does not support RM measurements on nonoperating channels; on receipt of a Radio Measurement Request frame requesting a measurement on nonoperating channels, the STA shall reject the measurement request by returning a Measurement Report element in which the Incapable subfield in the Measurement Report Mode field is 1. The

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

interpretation rules defined in Table 11-12 also apply for all nonzero values of dot11RMNonOperatingChannelMaxMeasurementDuration for measurements on nonoperating channels.

NOTE—Measurement duration on nonoperating channels is subject to further limitations due to maximum off-channel time.

If the Duration Mandatory subfield is 1 in the Measurement Request Mode field of a measurement request, the requested STA, if it accepts the request, shall perform the measurement over the Measurement Duration specified in the request. If the STA is unable to commit to making the measurement over the requested duration, it shall refuse the request by sending a measurement report in which the Refused subfield in the Measurement Report Mode field is set to 1. The measurement duration in the measurement report is equal to the requested measurement duration.

If the Duration Mandatory subfield is 0 in the Measurement Request Mode field of a measurement request, the requested STA, if it accepts the request, shall attempt a measurement using the requested duration as a maximum measurement duration, and may report results with an actual measurement duration less than the requested duration. The duration over which the measurement was made is included in the measurement duration field of the measurement report.

Each separate measurement within the Radio Measurement Request frame shall be performed over a continuous measurement time period. In Radio Measurement Request frames the requested Measurement Duration value shall not be set to 0 except when the request frame is a Beacon request in which the Measurement Mode field value is Beacon Table, or is a STA Statistics request, or is a request for triggered autonomous measurements.

11.10.5 Station responsibility for conducting measurements

A radio measurement-capable STA shall decode and interpret each Radio Measurement Request frame that it receives and shall assess the contents against its capabilities and the impact on its own performance. A measurement request may be refused by the receiving STA by sending a Radio Measurement Report frame in which the Refused subfield in the Measurement Report Mode field is set to 1. The reasons for refusing a measurement request are outside the scope of this standard but may include reduced quality of service, unacceptable power consumption, measurement scheduling conflicts, or other significant factors.

In assessing the performance impact of each Measurement Request element, a STA may use application-specific knowledge or other knowledge to limit the time it spends away from the operating channel. In doing so, the STA may either:

— Reject any Measurement Request element in which the Duration Mandatory subfield is 1 and that has a mandatory measurement duration exceeding the maximum allowed off-channel time, or
— Measure for a reduced duration if the Duration Mandatory subfield is 0.

A STA shall cancel all in-process radio measurements and shall delete all pending, unprocessed radio measurement requests upon receipt of a Disassociation frame or upon (re)association with a BSSID different from its most recent association.

11.10.6 Requesting and reporting of measurements

A STA may perform radio measurements on one or more channels itself or a STA may request STAs in the same BSS to perform measurements on its behalf.

A STA advertises its radio measurement capability using the RM Enabled Capabilities element. If a STA advertises that it is capable of a measurement, it shall not reject a request for the corresponding measurement by sending a Radio Measurement Report frame in which the Incapable subfield in the Measurement Report Mode field is set to 1, except as specified in 11.10.9.7. Measurement requests for radio measurements that the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

STA has advertised it is not capable of shall be rejected, and the corresponding report shall have the Incapable subfield in the Measurement Report Mode field set to 1.

When requesting other STAs to measure one or more channels, a STA shall use a Radio Measurement Request frame containing one or more Measurement Request elements. The measurement request may be sent to an individual or group destination address. The permitted measurement requests are shown in Table 11-13.

Table 11-13—Allowed measurement requests

Service set	Source of request	Destination of request	Receiver address of Radio Measurement Request frame
Infrastructure BSS	AP	Non-AP STA	Individual or group
	Non-AP STA	AP	Individual only
	Non-AP STA	Non-AP STA	Individual only for Direct Link within a BSS served by QoS AP, otherwise not allowed
IBSS	Non-AP STA	Non-AP STA	Individual or group
PBSS	PCP	STA	Individual or group
	STA	PCP	Individual only
	STA	STA	None

The source and destination of a measurement request shall both be a member of the same infrastructure BSS, a member of the same PBSS, or a member of the same IBSS. Measurement requests with an individual receiver address shall be sent only to STAs that have indicated radio measurement capability.

The set of requested measurements received in the most recently received Radio Measurement Request frame of highest precedence is active. The precedence order for measurement requests shall be as follows (highest precedence first):

— Measurement requests received in individually addressed Radio Measurement Request frames
— Measurement requests received in multicast-group addressed Radio Measurement Request frames
— Measurement requests received in broadcast Radio Measurement Request frames

The Measurement Request elements shall be processed in sequence by default, with certain Measurement Request elements processed in parallel according to the Parallel subfield setting: see 9.4.2.19. A STA shall accept a measurement request with the Parallel subfield enabled if dot11RMParallelMeasurementsActivated is true; otherwise, the STA shall reject the Measurement Request by returning a Measurement Report with the Incapable subfield in the Measurement Report Mode field set to 1.

If dot11RMParallelMeasurementsActivated is true and if measurement resources are available, the STA processes each element by setting up and making the specified measurement. If measurement resources are not available to perform the requested parallel measurements, the STA shall return a Measurement Report with the Refused subfield in the Measurement Report Mode field set to 1.

The Measurement Request elements within a Radio Measurement Request frame may specify multiple measurement types across multiple channels.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA may receive another Radio Measurement Request frame while the measurements requested in a previous Radio Measurement Request frame are pending or in progress. If this request is accepted, the set of measurement requests in the new frame supersedes any previous requests received in a Radio Measurement Request frame of the same or lower precedence. The measuring STA shall report the results of any completed measurements and terminate any pending or in-progress measurements. Results from a terminated in-progress measurement may be valid and reported if Duration Mandatory was not equal to 1 in the corresponding request. It is permissible for the superseding Radio Measurement Request frame to contain no new measurement requests. This has the effect of canceling all pending or in-progress measurements of the same or lower priority. If a station receives a Radio Measurement Request frame with lower precedence than the currently active Radio Measurement Request frame, the station shall discard the measurement requests in the new Radio Measurement Request frame. Measurement Request elements that have the Enable subfield equal to 1 shall be processed in all received Radio Measurement Request frames regardless of these precedence rules.

If a STA receives a Spectrum Measurement Request frame with Measurement Type field equal to 0 (Basic request), this shall take priority over any pending or in-progress radio measurements.

A STA that issues a radio measurement request to another STA to perform a measurement on the operating channel may continue to transmit MPDUs and MMPDUs to that STA while the measurement is being processed.

A STA that issues a radio measurement request to another STA to perform a measurement on a nonoperating channel is not required to take any special action to suspend traffic to that STA. All stations shall maintain state information such that data services and association or membership with the BSS continue when returning from a nonoperating channel measurement.

A single Measurement Request element may generate a large quantity of measurement report data. The measurement report data may be reported using multiple measurement report elements in multiple measurement report frames. The result of each measurement requested in a Measurement Request element shall be reported in one or more Measurement Report elements of type corresponding to the request. Each Measurement Report element returned shall have the same Measurement Token as in the corresponding Measurement Request element, and the same Actual Measurement Start Time field, if present, as in the first returned Measurement Report element. The results of each measurement should be returned without undue delay to the requesting STA.

Measurement Report elements shall be returned to the requesting STA in one or more Radio Measurement Report frames. Each Radio Measurement Report frame shall contain the same Dialog Token field value as the corresponding Radio Measurement Request frame, and the same Actual Measurement Start Time field, if present, as in the first returned Measurement Report element.

When a STA is permanently unable to make a requested measurement, the STA shall respond to such a measurement request received within an individually addressed Radio Measurement Request frame with a measurement report indicating that it is incapable of completing the measurement request. A STA shall not respond to requests received in group addressed frames in this manner. Examples of when a response of incapable is appropriate are

— The requested measurement type is not supported.
— The measuring STA cannot support requested parallel measurements due to the requests relating to different channels.

A STA that receives a response with an incapable indication shall not make the same request to the responding STA during the lifetime of the current association, or IBSS membership. This is logically the same as the responding STA using the Enable and Request subfields in a measurement request to indicate that it does not accept measurement requests of a certain type. A STA that has indicated an incapable response to a requesting STA may discard further requests of the same type from that STA without responding.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA may refuse to make any requested measurement. A STA refusing a measurement request within an individually addressed Radio Measurement Request frame shall respond with a measurement report indicating that it is refusing the measurement request. A STA shall not respond to measurement requests received in group addressed Radio Measurement Request frames in this manner.

By default, a STA may send a radio measurement request of any defined measurement type. A STA that receives a Measurement Request element with the Enable subfield equal to 1 and the Request subfield equal to 0 shall not issue a measurement request of the type specified in the request to the STA from which the element was received.

Since measurements on nonoperating channels interrupt normal operation on the operating channel, the requesting STA should consider each STA's service load, power state, and operating conditions. Since measurements on the operating channel execute concurrently with normal traffic processing, operating channel measurements can be requested more frequently and for longer durations.

11.10.7 Repeated Measurement Request frames

Radio Measurement Request frames contain a field specifying the number of repetitions for the Radio Measurement Request frame.

If the Radio Measurement Request frame includes a nonzero value for the Number of Repetitions and dot11RMRepeatedMeasurementsActivated is false, the STA shall reject the measurement request by returning a Measurement Report with the Incapable subfield in the Measurement Report Mode field set to 1.

If the Radio Measurement Request frame includes a nonzero value for the Number of Repetitions and dot11RMRepeatedMeasurementsActivated is true, the STA shall iterate (repeat) the processing of all of the Measurement Request elements in the frame as specified by the value in the Number of Repetitions field. A value of 0 in the Number of Repetitions field indicates Measurement Request elements are executed once without repetition; a value of 1 in the Number of Repetitions field indicates Measurement Request elements are executed twice, one initial execution and one repetition; and so on. When completing the initial processing of the last Measurement Request element in the frame, the STA shall begin processing of the first Measurement Request element in the frame to repeat the frame until the number of iterations reaches the value in the Number of Repetitions field. Measurement Request elements with the Enable subfield equal to 1 shall be processed once regardless of the value in the Number of Repetitions in the measurement request.

Each repeated measurement result shall include the same Measurement Token value as in the Measurement Token field of the corresponding Measurement Request element and the same Dialog Token field as in the Dialog Token field of the corresponding Radio Measurement Request frame.

Measurement results shall be reported for each repetition of a repeated measurement request subject to any conditional reporting requirement.

STAs responding with incapable or refused indications to measurement requests within a Radio Measurement Request frame with a nonzero value for Number of Repetitions shall respond only once.

11.10.8 Triggered autonomous reporting

Autonomous reporting is defined for spectrum management measurements supporting DFS; see 11.8.7. It allows a STA to report the results of measurements to a peer STA for which there was no explicit measurement request. In this case, the transmission of autonomous reports shall be entirely the decision of the STA at which such reporting has been enabled. An example of this use would be to report a change in conditions at the STA observed as a result of background measurement, e.g., the presence of a radar signal.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In radio measurement, triggered autonomous reporting shall be subject to trigger conditions set by the enabling STA that determine when measurement reports are issued. Triggered autonomous reporting provides a method for conditional reporting during continuous background measurements. An example of the use of triggered autonomous measurement is for reporting problem conditions in continuous, noninvasive statistical monitoring.

Triggered autonomous reporting is defined for the Transmit Stream/Category Measurement measurement type; see 11.10.9.8. When dot11MulticastDiagnosticsActivated is true, triggered autonomous reporting is used for Multicast Diagnostics reports (11.10.19). When dot11TriggerSTAStatisticsActivated is true, triggered autonomous reporting is used for STA Statistics reports (11.10.9.5).

If dot11RMTriggeredTransmitStreamCategoryMeasurementActivated is true, a STA indicates that it wishes to accept triggered autonomous reports by sending a Measurement Request element with the Enable and Report subfields set to 1; see 9.4.2.19. The type of measurement is indicated in the Measurement Type field. Trigger conditions that determine when measurement reports are to be generated shall be specified in the Measurement Request field. A Measurement Request element that is being used to control triggered autonomous reporting shall be sent within a Radio Measurement Request frame. Measurement Request elements being used to request measurements may also appear in the same Radio Measurement Request frame. The Radio Measurement Request frame may be sent to a group receiver address to enable triggered autonomous reports at more than one STA.

A STA shall not send autonomous reports for radio measurement types having triggered autonomous reporting enabled without a requested trigger condition having been met.

If a request to enable triggered autonomous reporting is sent to an individual address and the recipient STA does not support measurements of the type indicated or the recipient STA has dot11RMTriggeredTransmitStreamCategoryMeasurementActivated equal to false, a Measurement Report element shall be returned to the requesting STA with the Incapable Subfield set to 1. A STA may also refuse to enable triggered autonomous reporting. In this case a Measurement Report element shall be returned to the requesting STA with the Refused subfield set to 1. Such responses shall not be issued if the request to enable triggered autonomous reporting was sent to a group address.

A STA receiving a request to enable triggered autonomous reporting from another STA may send reports of the appropriate type, addressed to the individual address of the STA that sent the enable request. Autonomous reports shall be sent only to the individual addresses of STAs from which a valid enable request has been received and shall be issued only when a requested trigger condition has been met. The Measurement Token in each Measurement Report element and the Dialog Token field in the Radio Measurement Report frame shall both be set to 0 in a triggered autonomous report.

A STA may update the trigger conditions set for triggered autonomous reports by issuing a new Measurement Request element with the Enable and Report subfields both set to 1, the Measurement Type field set to the appropriate type and the Measurement Request field indicating the new trigger conditions. A STA disables all triggered autonomous measurement reports by sending a Measurement Request element with the Enable subfield set to 1 and the Report subfield set to 0; see 9.4.2.19.

A STA in an infrastructure BSS or PBSS shall cease all triggered autonomous reporting if it disassociates, or reassociates with a different BSS (reassociation to the same BSS shall not affect triggered reporting). An IBSS STA shall cease all triggered autonomous reporting if it leaves the BSS.

Triggered autonomous reporting and requested measurements are independent: a STA may request measurements from another STA even if it has enabled triggered autonomous reporting from that STA. All Measurement Request elements received in Radio Measurement Request frames that have the Enable subfield equal to 1 shall be processed without regard for the measurement precedence rules for requested measurements in 11.10.6.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A number of triggered measurements may run concurrently at a non-AP STA. The number of simultaneous triggered measurements supported is outside the scope of the standard. Each triggered measurement is logically separate; reporting conditions such as Trigger Timeout periods apply only to the measurement for which they are established.

11.10.9 Specific measurement usage

11.10.9.1 Beacon report

11.10.9.1.1 General

A Beacon report is, depending on context, the set of one or more frames responding to a Beacon request, or a single frame providing all or part of the response to a Beacon request.

If a STA accepts a Beacon request it shall respond with one or more Radio Measurement Report frames containing Beacon reports for all observed BSSs matching the BSSID and SSID in the Beacon request, at the level of detail requested in the Reporting Detail field of the Reporting Detail subelement (or the default shown in Table 9-144 if not present):

— If the Reporting Detail field equals 0, the Reported Frame Body subelement shall not be included in the Beacon report(s).

— If the Reporting Detail field equals 1, all fields, and any elements identified in a Request element and/or (an) Extended Request element(s) if present in the corresponding Beacon request, shall be included, subject to Beacon report truncation (see 11.10.9.1.2), in the Reported Frame Body subelement (or the Reported Frame Body subelements of multiple Beacon reports, in the case of Reported Frame Body subelement fragmentation), in the order that they appeared in the reported frame.

— If the Reporting Detail field equals 2, all fields and elements shall be included, subject to Beacon report truncation (see 11.10.9.1.2), in the order they appeared in the reported frame.

The RCPI in the Beacon report indicates the power level of the received Beacon, Measurement Pilot, or Probe Response frame. For repeated measurements (when the Radio Measurement Request frame contains a nonzero value for the Number of Repetitions field), the transmission of the Beacon report may be conditional on the measured RCPI or RSNI value. If the Radio Measurement Request frame contains a 0 value for the Number of Repetitions field, the Beacon Reporting subelement shall not be included in the Beacon request. If the Radio Measurement Request frame contains a nonzero value for the Number of Repetitions field, and if both dot11RMBeaconMeasurementReportingConditionsActivated and dot11RMRepeatedMeasurementsActivated are true, and if a Beacon Reporting subelement is included in a Beacon request, the STA shall respond with a Beacon report if the indicated Beacon reporting condition is true. Otherwise, the STA shall not respond with a Beacon report. Table 9-143 lists the reporting conditions that are based on the measured RCPI or RSNI levels.

If the requested Beacon report includes the Supported Operating Classes element, then the channel number, operating class, and/or reported frame information for that measurement may be included in the Beacon report; otherwise these fields shall be set to 255 in the Beacon report. The STA shall use the Reporting Detail field specified in the measurement request, or the default if not present, to determine the data to be included in the measurement report. If the STA has no beacon information available then the STA may either refuse the request or send an empty Beacon report.

If dot11RMBeaconPassiveMeasurementActivated is true and the measurement mode in the measurement request is Passive, the measuring STA shall perform the following procedure (or an equivalent procedure) on the requested channel:

— Set a measurement duration timer.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— At the end of the measurement duration, process all received Beacons or Probe Response frames with the requested SSID and BSSID to compile the measurement report. The STA shall use the Reporting Detail field specified in the measurement request, or the default if not presemt, to determine the data to be included in the measurement report. If no Beacon or Probe Response frames with the requested SSID and BSSID were received in the measurement duration, then process all Measurement Pilot frames with the requested BSSID to compile the measurement report. Otherwise, compile an empty Beacon report.

If dot11RMBeaconPassiveMeasurementActivated is false and the measurement mode in the measurement request is Passive, the measuring STA shall reject the measurement request by returning a Beacon report with the Incapable subfield in the Measurement Report Mode field set to 1.

If dot11RMBeaconActiveMeasurementActivated is true and the measurement mode in the measurement request is Active, the measuring STA shall perform the following procedure (or an equivalent procedure) on the requested channel, if permitted (e.g. the channel is not subject to DFS):

— If the channel is not the operating channel, wait for dot11RMMeasurementNavSync, or until a PHY-RXSTART.indication primitive has been received.
— Using the basic access protocol in 10.3.4.2, send a Probe Request frame to the broadcast address. The BSSID field in the Probe Request frame shall be set to the BSSID field in the measurement request. The SSID element in the Probe Request frame shall be set to the SSID element in the measurement request.
— Set a measurement duration timer.
— At the end of the measurement duration, process all received Probe Response and Beacon frames with the requested SSID and BSSID to compile the measurement report. The STA shall use the Reporting Detail field specified in the measurement request, or the default if not present, to determine the data to be included in the measurement report. If no Beacons or Probe Response frames were received in the measurement duration and Measurement Pilot frames with the requested BSSID were received in the measurement duration, then process all these Measurement Pilot frames to compile the measurement report. Otherwise, compile an empty Beacon report.

If dot11RMBeaconActiveMeasurementActivated is true, the measurement mode in the measurement request is Active, and the measurement on the requested channel is not permitted (e.g., the channel is subject to DFS), the measuring STA shall reject the measurement request by returning a Beacon report with the Refused subfield or the Incapable subfield in the Measurement Report Mode field set to 1.

If dot11RMBeaconActiveMeasurementActivated is false and the measurement mode in the measurement request is Active, the measuring STA shall reject the measurement request by returning a Beacon report with the Incapable subfield set in the Measurement Report Mode field.

When more than one Beacon or Probe Response from a BSS is received in the measurement duration, the contents of the Beacon report shall be based on the latest received. If only Measurement Pilot frames were received in the measurement duration, the contents of the Beacon report shall be based on the latest Measurement Pilot frame received.

If the BSSID field in the Measurement Request contains a wildcard BSSID, all observed BSSs with the requested SSID shall be reported in a separate Beacon report for each BSSID. If the SSID subelement is not included in the Beacon request, all observed BSSs shall be reported in a separate Beacon report for each BSSID. In active mode, Probe Response frames shall be evaluated regardless of whether the Probe Response frame was triggered by the measuring STA's Probe Request.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

On accepting an active or passive mode Beacon request, a STA shall conduct measurements as follows:

— If the Channel Number is 0 and the Operating Class identifies the location of the primary channel, then a STA shall conduct iterative measurements on all supported channels in the specified Operating Class where the measurement is permitted on the channel and the channel is valid for the current regulatory domain.
— If the Channel Number is 0 and if the Operating Class encompasses a primary channel but does not identify the location of the primary channel, then a STA shall conduct iterative measurements on all primary channel positions within all requested and supported channels where the measurement is permitted on the channel and the channel is valid for the current regulatory domain.
— If the Channel Number is 255, the Operating Class identifies the location of the primary channel, and the Beacon request includes AP Channel Report subelements, a STA shall conduct iterative measurements on all supported channels listed in the AP Channel Report subelements that are valid for the current regulatory domain. If there is no AP Channel Report subelement included in the Beacon request, a STA shall conduct iterative measurements on all supported channels listed in the latest AP Channel Report received from the serving AP that are valid for the current regulatory domain. If there are no AP Channel Report subelements included in the Beacon request, and no AP Channel Report included in last received AP Beacon frame, the STA shall reject the Beacon request.
— If the Channel Number is 255, the Operating Class encompasses a primary channel but does not identify the location of the primary channel, and the Beacon request includes AP Channel Report subelements, then a STA shall conduct iterative measurements on all primary channel positions within all requested (in the AP Channel Report) and supported channels that are valid for the current regulatory domain. If there are no AP Channel Report subelements included in the Beacon request, the STA shall reject the Beacon request.
— If the Channel Number is a value other than 0 or 255, a STA shall conduct iterative measurements on the requested channel, where the measurement is permitted on the channel and the channel is valid for the current regulatory domain.

Except when the Measurement Mode field is equal to Beacon Table, measurements shall be made using the specified Measurement Duration with the time between each consecutive measurement as defined in 11.10.2. Iterative measurements shall cease when all channels have been measured. While the STA is processing a Beacon request for iterative channel measurements, the STA shall not begin processing the next measurement request in the Radio Measurement Request frame.

If dot11RMBeaconTableMeasurementActivated is true and the measurement mode in the measurement request is Beacon Table, the measuring STA shall return a Beacon report containing the current contents of any stored beacon information for any supported channel with the requested SSID and BSSID without performing additional measurements. The receiving STA shall ignore the channel and measurement duration specified in the Beacon request when the Measurement Mode field contains Beacon Table. The beacon information accumulated may be the result of any operation that caused the STA to acquire these results. If the stored beacon information is based on a measurement made by the reporting STA, and if the actual measurement start time, measurement duration, and Parent TSF are available for this measurement, then the Beacon report shall include the actual measurement start time, measurement duration, and Parent TSF; otherwise the actual measurement start time, measurement duration, and Parent TSF shall be set to 0. The RCPI and RSNI for that stored beacon measurement may be included in the Beacon report; otherwise the Beacon report shall indicate that RCPI and RSNI measurements are not available.

If dot11RMBeaconTableMeasurementActivated is false and the measurement mode in the measurement request is Beacon Table, the measuring STA shall reject the measurement request by returning a Beacon report with the Incapable subfield set in the Measurement Report Mode field.

For repeated measurements, the Beacon request may include a Beacon Reporting subelement that determines when the measuring STA is to send a Beacon report for a measured Beacon, Measurement Pilot, or Probe

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Response frame with the requested SSID and BSSID. When the requested Reporting Condition value is nonzero, and dot11RMBeaconMeasurementReportingConditionsActivated is true, the STA shall create and transmit a Beacon report for that measured frame if the condition indicated in Table 9-143 is true. Otherwise, the STA shall not transmit a Beacon report for that measured frame. If multiple Beacon, Measurement Pilot, or Probe Response frames with the requested specific BSSID are received during the measurement duration, the reporting condition shall be applied only to the latest received Beacon, Measurement Pilot, or Probe Response frame. If multiple Beacon, Measurement Pilot, or Probe Response frames are received during the measurement duration when a wildcard BSSID is requested, the STA shall generate one Beacon report for each BSSID occurring in frames that satisfy the reporting condition; the Beacon report shall be based on the latest received Beacon, Measurement Pilot, or Probe Response frame for that specific BSSID. For reporting conditions 5–10, the serving AP's reference RCPI level and the serving AP's reference RSNI level referred to in Table 9-143 are average values of the RCPI or RSNI of the 16 most recent Beacon frames received from the measuring STA's serving AP. The serving AP's reference RCPI level and the serving AP's reference RSNI level are so averaged to provide a more accurate and stable indication of the signal level from the serving AP. For reporting conditions 5–10, the STA shall use the serving AP's reference RCPI level or reference RSNI level (with offset, if any) to test the measured RCPI or RSNI to determine whether to create and send a Beacon report for this measured Beacon, Measurement Pilot, or Probe Response frame.

The STA shall return a Beacon report with the Incapable subfield set in the Measurement Report Mode field in the following cases:

— Reporting Condition in the Beacon request is nonzero and dot11ReportingConditionsActivated is false,

— Reporting Condition in the Beacon request is nonzero and the Number of Repetitions in the Radio Measurement Request frame is 0.

NOTE 1—Reporting conditions described here for repeated Beacon request measurements are distinct from the conditions defined elsewhere for triggered measurements.

A STA that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Beacon request or Beacon report. A STA shall not include a Wide Bandwidth Channel Switch subelement in a Beacon request or Beacon report sent to a STA that is not extended spectrum management capable. If the Wide Bandwidth Channel Switch subelement is included in a Beacon request or Beacon report, then the Operating Class shall indicate a 40 MHz channel spacing.

If N (where $N \geq 1$) AP Channel Report subelements containing an Operating Class with an 80+ behavior limit (the 80+ behavior limit is defined in Table D-2, the operating classes that might use this limit are defined in E.1) are included contiguously in a Beacon request, then the N subelements shall be followed by one AP Channel Report subelement containing an Operating Class without an 80+ behavior limit (as defined in Annex E). All N+1 Channel List fields in each of these subelements shall contain the same number L of channel numbers. This sequence of N+1 AP Channel Report subelements indicates a list of L noncontiguous channels comprising N+1 frequency segments, where the lth channel number in the nth Channel List field identifies the channel center frequency of the nth frequency segment.

NOTE 2—To identify the BSS bandwidth, the Beacon request might include a Request subelement listing the element IDs of the HT Operation and VHT Operation elements. The Beacon report would then include the requested elements, which contain fields defining the BSS bandwidth.

When a Beacon request includes a Last Beacon Report Indication Request subelement with the Data field equal to 1, the reporting STA shall include a Last Beacon Report Indication subelement in the Beacon report, and set the Data field of the subelement to 1 when that is the last frame of the sequence of frames generated as a response to a Beacon request. Otherwise the Data field is set to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.10.9.1.2 Truncation and/or fragmentation of reported frame body in Beacon report

If a Reported Frame Body subelement in a Beacon report would exceed the maximum subelement size or would cause the Measurement Report element in the Beacon report to exceed the maximum element size, and the STA transmitting the Beacon report supports Reported Frame Body subelement fragmentation, the Reported Frame Body subelement shall be fragmented as follows:

— The payload of the Reported Frame Body subelement is fragmented across two or more Beacon reports
— A Reported Frame Body Fragment ID subelement is present in each Beacon report
— The Beacon Report ID subfield in the Reported Frame Body Fragment ID subelement of each Beacon report is the same, and is different from that of Beacon reports corresponding to a different reported frame
— The Fragment ID Number subfield in the Reported Frame Body Fragment ID subelement of the first Beacon report is set to 0 and is incremented by 1 for each subsequent Beacon report
— The More Frame Body Fragments field in the Reported Frame Body Fragment ID subelement is set to 1 in all except the last Beacon report
— Elements in the Reported Frame Body subelement are not truncated, split across two Beacon reports, or omitted

NOTE 1—This means the last element in the Reported Frame Body subelement of each Beacon report is a complete element.

NOTE 2—The STA requesting a Beacon report needs to support Reported Frame Body subelement (de)fragmentation unless it sets the Reporting Detail subelement in the Beacon request to ensure the STA sending the Beacon report does not use fragmentation.

If a Reported Frame Body subelement in a Beacon report would exceed the maximum subelement size or would cause the Measurement Report element in the Beacon report to exceed the maximum element size, and the STA transmitting the Beacon report does not support Reported Frame Body subelement fragmentation, reported elements shall be truncated or omitted as follows to make them fit:

— A TIM element may be truncated such that only the first 4 octets of the element are reported and the element Length field is modified to indicate the truncated length of 4.
— A IBSS DFS element may be truncated so that only the lowest and highest channel number map are reported and the element Length field is modified to indicate the truncated length of 13.
— An RSNE may be truncated so that only the first 4 octets of the element are reported and the element Length field is modified to indicate the truncated length of 4.
— Elements may be omitted from the end of Reported Frame Body subelement.

NOTE 3—Elements are not truncated or omitted if the STA transmitting the Beacon report supports Reported Frame Body subelement fragmentation.

11.10.9.2 Frame report

If dot11RMFrameMeasurementActivated is true, and a station accepts a Frame request, it shall respond with a Radio Measurement Report frame containing one or more Measurement Report elements with the Measurement Type field set to Frame. (See 9.4.2.20.8.)

If the MAC Address field included in the Frame request was not set to the broadcast address, the measuring station shall report, in one or more Frame reports, only those Data or Management frames received during the measurement duration with a TA field matching the MAC Address field of the Frame request, if at least one such frame was received. If the MAC address field included in the Frame request was set to the broadcast

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

address, the measuring station shall report all Data or Management frames received during the measurement duration in one or more Frame reports.

If the Frame Request Type of the corresponding Frame request equals 1, then each Frame report contains one Frame Count subelement that contains in turn one or more Frame Report Entries.The measuring station shall count the number of individually addressed Data and Management frames received from one transmitter address during the measurement duration and shall summarize this traffic in a frame report entry.

The reported Average RCPI shall be an average of the RCPI values of frames received and counted in the Frame Report Entry field. If there are up to 32 frames, then the Average RCPI indicates the mean of the RCPI of each of the frames. If there are more than 32 frames, then the Average RCPI indicates an exponentially weighted average, initialized by the mean RCPI of the first 32 frames and exponentially updated by new RCPI values. The averaging is calculated as depicted as follows.

If the number of frames received is less than or equal to 32:

Average RCPI = Sum of RCPI values / Number of frames

For 33 received frames and above:

Average RCPI = (Last Average RCPI × 31 / 32) + (Current frame RCPI / 32)

The Last RCPI shall be the RCPI value of the most recently received frame counted in the Frame Report Entry field. The Antenna ID field contains the identifying number for the antenna(s) or DMG antenna used to receive the most recently received frame included in this Frame Report Entry field as defined in 9.4.2.38. If different antennas are used to receive the frame preamble and the frame body, this antenna ID or DMG antenna ID shall contain the identifying number for the antenna(s) used to receive the frame body.

If dot11RMFrameMeasurementActivated is false, a station shall reject the received Frame request by returning a Frame report in which the Incapable subfield in the Measurement Report Mode field is 1.

A STA that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Frame request or Frame report. A STA shall not include a Wide Bandwidth Channel Switch subelement in a Frame request or Frame report sent to a STA that is not extended spectrum management capable. If the Wide Bandwidth Channel Switch subelement is included in a Frame request or Frame report, then the Operating Class shall include a 40 MHz channel spacing.

11.10.9.3 Channel load report

If dot11RMChannelLoadMeasurementActivated is true and a station accepts a Channel Load request, it shall respond with a Radio Measurement Report frame containing one Measurement (Channel Load) Report element. The Channel Load field is defined as the percentage of time, linearly scaled with 255 representing 100%, the STA sensed the medium was busy, as indicated by either the virtual carrier sense mechanism or the physical carrier sense mechanism over the requested channel width (together referred to as the *CS mechanism*). This percentage is computed using the following formula:

$$\text{Channel Load} = \left\lfloor \frac{\text{channel busy time}}{\text{MeasurementDuration} \times 1024} \times 255 \right\rfloor$$

where channel busy time is defined to be the number of microseconds during which the CS mechanism, as defined in 10.3.2.1, has indicated a channel busy indication for the requested channel width.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If dot11RMChannelLoadMeasurementActivated is false, a station shall reject the received Channel Load request by returning a Channel Load report with the Incapable subfield in the Measurement Report Mode field set to 1.

If dot11RMChannelLoadMeasurementActivated is true and if a Channel Load Reporting subelement is included in a Channel Load request, the STA shall respond with a Channel Load report if the indicated channel load reporting condition is true. Otherwise, the STA shall not respond with a Channel Load report.

A STA that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Channel Load request or Channel Load report. A STA shall not include a Wide Bandwidth Channel Switch subelement in a Channel Load request or Channel Load report sent to a STA that is not extended spectrum management capable. If the Wide Bandwidth Channel Switch subelement is included in a Channel Load request or a Channel Load report, then the Operating Class shall indicate a 40 MHz channel spacing.

11.10.9.4 Noise Histogram report

If dot11RMNoiseHistogramMeasurementActivated is true and a station accepts a Noise Histogram request, it shall respond with a Radio Measurement Report frame containing one Measurement (Noise Histogram) Report element. The Noise Histogram report shall contain the IPI densities observed in the channel for the IPI levels defined in Table 9-166.

To compute the IPI densities, a STA shall measure the amount of time, in microseconds, during which the IPI is in each IPI range specified in Table 9-166. These IPI measurements shall be taken over the entire associated channel bandwidth, and during the requested measurement duration except for those time intervals during which the NAV is not equal to 0 (when virtual CS mechanism indicates channel busy), or during which frame transmission or reception is occurring. The IPI densities are then computed for each of the nine possible IPI values using:

$$\text{IPI Density} = \text{Integer}\left[\frac{255 \times D_{IPI}}{(1024 \times D_M) - T_{NAV} - T_{TX} - T_{RX}}\right]$$

where

D_{IPI} is the duration receiving at the specified IPI value (μs)
D_M is the measurement duration (TU)
T_{NAV} is the total time that NAV is nonzero during the Measurement Duration (μs)
T_{TX} is the frame transmission time during the Measurement Duration (μs)
T_{RX} is the frame reception time during the Measurement Duration (μs)

The sum of the IPI densities is approximately 255. If either the NAV is nonzero, or if there is frame transmission, or if there is frame reception throughout the entire measurement duration period, no reportable IPI values are measured, and all IPI Densities shall be set to 0 in the Measurement Report element.

A STA shall include in the Noise Histogram report an average noise power indicator (ANPI) value representing the average noise plus interference power on the measured channel at the antenna connector during the measurement duration. The STA may use Noise Histogram IPI density values to calculate ANPI. The IPI densities in the Noise Histogram report may be used to calculate an average noise power for the channel during the measurement duration. This calculated average IPI power value may be reported as the value for ANPI. Any equivalent method to measure ANPI may also be used. ANPI power is defined in dBm using the same accuracy as defined for RCPI.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

ANPI may be calculated in any period and at any time by filtering all PHY IPI values in a MAC filter to exclude IPI values received when NAV is nonzero. These filtered IPI values represent idle channel noise and may be stored in a first-in-first-out (FIFO) buffer to facilitate ANPI calculation over a fixed number of IPI samples. ANPI may be so calculated upon receipt of any frame and may be used with RCPI to calculate RSNI for any received frame. Any equivalent method to measure ANPI may also be used to calculate RSNI for any received frame.

If dot11RMNoiseHistogramMeasurementActivated is false, a station shall reject the received Noise Histogram request by returning a Noise Histogram report with the Incapable subfield in the Measurement Report Mode field set to 1.

If dot11RMNoiseHistogramMeasurementActivated is true and if a Noise Histogram Reporting subelement is included in a Noise Histogram request, the STA shall respond with a Noise Histogram report if the indicated noise histogram reporting condition is true. Otherwise the STA shall not respond with a Noise Histogram report.

A STA that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Noise Histogram request or Noise Histogram report. A STA shall not include a Wide Bandwidth Channel Switch subelement in a Noise Histogram request or Noise Histogram report sent to a STA that is not extended spectrum management capable. If the Wide Bandwidth Channel Switch subelement is included in a Noise Histogram request or a Noise Histogram report, then the Operating Class shall indicate a 40 MHz channel spacing.

11.10.9.5 STA Statistics report

If dot11RMStatisticsMeasurementActivated is true and a station accepts a STA Statistics request, it shall respond with a Radio Measurement Report frame including one STA Statistics report. If the Requested Measurement Duration value is 0, the STA shall report the current values for the requested Statistics Group Data. If the Requested Measurement Duration value is greater than 0, the STA Statistics report reports the change in the requested Statistics Group Data measured within that nonzero Measurement Duration. The reported change in data value shall be the value of the data at the end of the actual Measurement Duration minus the value of the data at the beginning of the actual Measurement Duration. If a STA accepts a STA Statistics request measurement with nonzero, positive Measurement Duration, the STA shall perform the measurement over the requested Measurement Duration without regard to the Duration Mandatory subfield in the Measurement Request Mode field. If a STA cannot measure over the requested Measurement Duration, the STA shall refuse the Statistics request measurement.

If dot11RMStatisticsMeasurementActivated is false, a station shall reject the received STA Statistics request by returning a Statistics Measurement Report with the Incapable subfield in the Measurement Report Mode field set to 1.

A STA may request that a STA Statistics report be sent when statistics of interest reach a threshold as defined in the Measurement Request element of the STA Statistics request frame (see 9.4.2.19.9). This is termed a triggered STA Statistics measurement. Implementation of Triggered STA Statistics Reporting is optional for a WNM STA. A STA that implements Triggered STA Statistics Reporting has dot11TriggerSTAStatisticsImplemented equal to true. When dot11TriggerSTAStatisticsImplemented is true, dot11WirelessManagementImplemented shall be true.

A triggered STA Statistic measurement shall be requested by setting the Enable and Report subfields to 1 within a Measurement Request element with the Measurement Type field set to STA Statistics. The Measurement Request field shall contain a STA Statistics request with the trigger conditions specified in the Triggered Reporting subelement, as defined in 9.4.2.19.9. One or more trigger conditions shall be set with specified thresholds. See 11.10.8. To prevent generation of too many triggered reports, the value of the Trigger Timeout field shall be set to greater or equal to dot11MinTriggerTimeout. If the Trigger Timeout field is less

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

than dot11MinTriggerTimeout, the STA shall reject the measurement request by returning a report where the Measurement Report Mode field is "Incapable."

A STA accepting a triggered STA Statistics measurement shall measure the requested statistics. If a trigger condition occurs, the measuring STA shall send a STA Statistics measurement report to the requesting STA. The measuring STA shall not send further triggered STA Statistics reports for that trigger condition to the requesting STA until the Trigger Timeout period specified in the request frame has expired. The STA Statistics measurement report is defined in 9.4.2.19.9. If the number of MPDUs or MSDUs indicated in the Measurement Count field are transmitted or received without any of the counted statistics meeting the corresponding trigger threshold then the measuring STA shall restart measuring for another measurement count window.

If a STA receives a STA Statistics request from the same STA for which a triggered STA Statistics measurement is in progress, the in-progress triggered measurement shall be terminated.

STA Statistics reported in a triggered STA Statistics report shall be the values accumulated over the number of transmitted or received MSDUs or MPDUs before the trigger condition is met. Measurement duration shall not be specified when requesting a triggered STA statistics measurement and the Measurement Duration field in the corresponding Measurement Request shall be set to 0.

All triggered STA Statistics measurements shall be terminated at a measuring STA by receiving a STA Statistics request with the Enable subfield equal to 1 and the Report subfield equal to 0. A STA requesting a triggered STA Statistics measurement may update the trigger conditions by sending a STA Statistics request specifying the new trigger conditions.

Once accepted by a measuring STA, a triggered STA Statistics measurement continues to be active until the measurement request is superseded by a STA Statistics request from the requesting STA or the measuring STA disassociates or reassociates.

11.10.9.6 LCI report (Location configuration information report)

If dot11RMLCIMeasurementActivated is true, a STA that receives an LCI request for location information that is not available shall respond with a Radio Measurement Report frame including a Radio Measurement Report element with the Refused subfield set to 1. If dot11RMLCIMeasurementActivated is true and a STA accepts an LCI request that does not include an azimuth request, it shall respond with a Radio Measurement Report frame including one LCI subelement (LCI report). If both dot11RMLCIMeasurementActivated and dot11RMLCIAzimuthActivated are true, and the STA accepts an LCI request that includes an azimuth request, it shall respond with a Radio Measurement Report frame that includes one LCI subelement (LCI report) and the requested Azimuth Report, if available. If dot11RMLCIAzimuthActivated is false, a STA that receives an LCI request that includes an azimuth request shall respond with a Radio Measurement Report frame including an Radio Measurement Report element with the Incapable subfield set to 1.

The Datum value shall be 1 (World Geodetic System 1984), unless another datum is required for operation in the regulatory domain.

If the Altitude Type is 2 (Floors of Altitude), the value reported shall be as required for operation in the regulatory domain.

An LCI request shall indicate a location request for the requesting STA, the reporting STA, or a third STA with the MAC address specified in the Target MAC Address subelement, by setting the LCI request Location Subject field to indicate a Local, a Remote, or a third-party request, respectively. Local LCI request is used by the requesting STA to obtain its own location by asking "Where am I?" Remote LCI request is used by requesting STA to obtain location of reporting STA by asking "Where are you?" Third-party location request is

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

used by requesting STA to obtain location of a STA with the MAC address specified in the Target MAC Address subelement.

The Latitude, Longitude, and Altitude fields of the LCI report shall be reported at their best known resolutions unless otherwise configured.

If the STA receiving an LCI request has no location information about the requested LCI subject's physical location, the STA shall send a LCI subelement indicating an unknown LCI (see 9.4.2.20.10). If the STA receiving an LCI request has no location information about the requested Azimuth, the STA shall omit the Azimuth Report subelement. If the STA receiving an LCI request that contains a Maximum Age subelement has already determined the requested LCI within the indicated maximum age, the STA may respond with its already determined LCI; otherwise, the STA shall update its LCI before the STA responds with its LCI. The method by which the physical location and azimuth information in the LCI report is generated is outside the scope of this standard.

A STA that receives an LCI report that contains a Usage Rules/Policy subelement shall process the LCI information in compliance with the retransmission and retention permissions in the Usage-rules subelement.

NOTE 1—A STA that requested an LCI including an Azimuth Request, and received an LCI report in which the Incapable subfield is 1 might alternatively request the LCI with no Azimuth requested.

If dot11RM3rdPartyMeasurementActivated is false, a STA that receives an LCI request that includes an LCI request with the Location Subject field equal to 2 shall respond with a Radio Measurement Report frame including an Radio Measurement Report element with the Incapable subfield set to 1.

It is optional for a STA to support an LCI request and an LCI report with the Location Subject field equal to 2. If dot11RM3rdPartyMeasurementActivated is true and a STA supports LCI request and LCI report, the following procedure shall be followed:

— When a non-AP STA requests the geospatial location of a STA with the MAC address specified in the Target MAC Address field, it shall also include its own MAC address in the Originator Requesting STA MAC address field. When an AP receives an LCI request with the Location Subject field value equal to 2, the AP shall generate an LCI request to the STA with the MAC address specified in the Target MAC Address field. If the AP does not have an association with the STA with the MAC address specified in the Target MAC Address field, the AP shall reject the received LCI request by returning an LCI report where the Incapable subfield is set in the MeasurementReport Mode field. The AP shall copy the Originator Requesting STA MAC address and Target MAC Address fields into the request from the received LCI request.

— When a STA receives an LCI request with the Location Subject field value equal to 2, the STA may generate an LCI report if the MAC address in the Target MAC Address field is its own MAC address; it shall not generate an LCI report otherwise. When an LCI report is generated, the reporting STA shall include its MAC address into the Target MAC Address field and the MAC address present in the Originator Requesting STA MAC address field of the corresponding LCI request into the Originator Requesting STA MAC address field. When an AP receives an LCI report with an Originator Requesting STA MAC address field present, the AP shall generate an LCI report to the associated STA with the MAC address specified in the Originator Requesting STA MAC address field. The AP shall copy the Originator Requesting STA MAC address and Target MAC Address fields into the LCI report being transmitted to the originating requesting STA.

If dot11RMLCIMeasurementActivated is false, a station shall reject the received LCI request by returning an LCI report with the Incapable subfield in the Measurement Report Mode field set to 1.

If dot11RMLCIMeasurementActivated is true and a STA has its own location configured in LCI format excluding an unknown LCI as defined in 9.4.2.19.10, the STA shall set dot11RMLCIConfigured to true.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 2—It is recommended that User Applications not send location information to other stations without the express permission of the user. User agents acquire permission through a user interface, unless they have prearranged trust relationships with users. Those permissions that are acquired through the user interface and that are preserved beyond the current browsing session (i.e., beyond the time when the BSS connection is terminated) are revocable and receiving stations should respect revoked permissions. Some user applications might have prearranged trust relationships that do not require such user interfaces. For example, while a social networking application might present a user interface when a friend performs a location request, a VOIP telephone might not present any user interface when using location information to perform an E911 function.

11.10.9.7 Measurement pause

A measurement pause is used within a Radio Measurement Request frame to provide a time delay between the processing of two other Measurement Request elements within the sequence of Measurement Request elements in that frame.

If a STA accepts a Measurement Pause request it shall delay processing of the next measurement request in the Radio Measurement Request frame. If the Measurement Pause request is the last Measurement Request element in a repeated Radio Measurement Request frame, the STA shall delay processing the first Measurement Request element in the Radio Measurement Request frame for the next repeat. In each case the delay shall be no less than the Pause Time value specified in the Measurement Pause request.

NOTE—Measurement pause is always supported by a STA implementing radio measurements.

A measurement pause shall not be sent as the only Measurement Request element in a Radio Measurement Request frame. A measurement pause shall not be included as the last Measurement Request element in a Radio Measurement Request frame that has the Number of Repetitions field equal to 0.

A measurement pause cannot be processed in parallel to other measurements. If the Parallel subfield is 1 in the Measurement Request element immediately prior to a measurement pause, an incapable response shall be returned even if dot11RMParallelMeasurementsActivated is true.

There is no measurement report associated with a Measurement Pause request.

11.10.9.8 Transmit Stream/Category Measurement report

The Transmit Stream/Category Measurement applies to TIDs for Traffic Streams associated with TSPECs and also to TIDs for Traffic Categories for QoS traffic without TSPECs.

If dot11RMTransmitStreamCategoryMeasurementActivated is true and has no resource constraint that prevents it from being able to make the requested measurement, a QoS STA receiving a Transmit Stream/ Category Measurement request shall respond with a Radio Measurement Report frame containing one Measurement (Transmit Stream/Category Measurement) Report element. If the traffic stream (TS) that is corresponding to the Traffic Identifier is deleted, either by a DELTS frame or by disassociation, the STA shall cease sending Radio Measurement Reports.

If dot11RMTransmitStreamCategoryMeasurementActivated is false, a STA shall reject the received Transmit Stream/Category Measurement request by returning a Transmit Stream/Category Measurement report with the Incapable subfield in the Measurement Report Mode field set to 1.

The transmit stream/category measurement shall be made on traffic that is transmitted from the measuring QoS STA to the peer QoS STA and TID indicated in the request. The Peer STA Address may be the MAC address of the QoS STA from which the Measurement Request was sent, the MAC address of another QoS STA within the BSS, or the broadcast address. A broadcast address shall be used only with a TID corresponding to a TC. In the case of a broadcast address, measurement shall be made on all traffic for the specified TC. Depending on policy, a QoS AP may disallow transmit stream/category measurement requests for traffic to other QoS STAs

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

in the BSS. In this case the QoS AP shall respond with a matching Radio Measurement Report frame with the Incapable subfield of the Measurement Report Mode field set to 1.

If, during the course of a Transmit Stream/Category Measurement, any counter that is included in the Transmit Stream/Category Measurement report increments to a value of 2^{32}–1, the Transmit Stream/Category Measurement shall terminate, and the Transmit Stream/Category Measurement report shall indicate the shortened, actual measurement duration.

If the measurement request included multiple transmit stream/category measurement requests for multiple TIDs, the corresponding measurement report shall include a transmit stream/category measurement report for each unique TID in the request that has been admitted. If the measurement request is for a TID that has not been admitted yet, a report is generated only after the TID becomes admitted.

The requesting and reporting STAs are QoS STAs. A non-QoS STA receiving a Transmit Stream/Category Measurement request shall reject the request by returning an indication of incapable.

A QoS STA may request that a measuring QoS STA send a transmit stream/category measurement report when the number of TID-specified MSDUs are discarded or delayed reaches a specified threshold. This is termed a triggered transmit stream/category measurement and shall be requested by setting the Enable and Report subfields to 1 within a Measurement Request element containing the Transmit Stream/Category Measurement Type. The Measurement Request field shall contain a Transmit Stream/Category Measurement request with the trigger conditions specified in the Triggered Reporting subelement. One or more trigger conditions may be set with specified thresholds. See 9.4.2.19.11.

Depending on policy, a QoS AP might not permit the establishment of triggered transmit stream/category measurement. Such a QoS AP receiving a triggered transmit stream/category measurement request shall give an incapable indication. The number of simultaneous triggered transmit stream/category measurements supported at a QoS STA is outside the scope of the standard. A STA shall respond to further requests with a refused indication if the number of simultaneous triggered QoS measurements supported by the STA is reached.

If dot11RMTriggeredTransmitStreamCategoryMeasurementActivated is true, a QoS STA shall accept a triggered Transmit Stream/Category Measurement and shall reject it otherwise. A QoS STA accepting a triggered QoS measurement shall measure the requested TC or TS. If a trigger condition occurs, the measuring QoS STA shall send a Transmit Stream/Category Measurement report to the requesting QoS STA. The measuring QoS STA shall not send further triggered QoS reports until the Trigger Timeout period specified in the request has expired or new trigger conditions have been requested. Measurement of transmit stream/category metrics shall continue during the reporting timeout period. Reporting shall resume following the Trigger Timeout period, or immediately following the acceptance of new trigger conditions.

If a QoS STA receives a Transmit Stream/Category Measurement request for a TC, or TS that is already being measured using a triggered transmit stream/category measurement, the triggered traffic stream measurement shall be suspended for the duration of the requested traffic stream measurement. When triggered measurement resumes, the traffic stream metrics shall be reset.

Traffic stream metrics reported in a triggered transmit stream/category measurement report shall be the values accumulated over the number of successfully and unsuccessfully transmitted MSDUs prior to the trigger event given in the Measurement Count field of the transmit stream/category measurement request that established the trigger condition. It is possible that a consecutive or delay trigger event occurs after acceptance of a triggered transmit stream/category measurement but before the number of MSDUs in Measurement Count has been transmitted. In this case the report shall be the values accumulated since measurement started. The measurement count value appears in the Transmitted MSDU Count field of a triggered transmit stream/category measurement report. Measurement duration shall not be used in triggered QoS measurement, and the Measurement Duration field in both the Measurement Request and any Measurement Report shall be set to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The Measurement Start Time field of a triggered transmit stream/category measurement report shall contain the value of the QoS STA TSF timer at the time the trigger condition occurred to an accuracy of 1 TU.

Once accepted by a measuring QoS STA, a triggered QoS measurement continues to be active until

— The relevant TS is deleted,
— The measuring QoS STA or QoS STA that requested the measurement disassociates or successfully reassociates, or
— The measurement is terminated by the requesting QoS STA.

All triggered QoS measurements shall be terminated at a measuring QoS STA by receiving a triggered transmit stream/category measurement request with the Enable subfield equal to 1 and the Report subfield equal to 0. A triggered QoS measurement request with no trigger conditions specified in the Trigger Conditions field shall terminate a triggered QoS measurement for the TC or TS specified in the request. A QoS STA requesting a triggered QoS measurement may update the trigger conditions by sending a triggered transmit stream/category measurement request specifying the new trigger conditions.

11.10.9.9 Location Civic report

If dot11RMCivicMeasurementActivated is true and civic location information is not available, the STA shall reject a Location Civic request by returning a Radio Measurement Report frame including a Measurement Report element with the Refused subfield set to 1. If dot11RMCivicMeasurementActivated is true and civic location information is available, the STA shall respond with a Radio Measurement Report frame including one Location Civic report.

A Location Civic request shall indicate a location request for the requesting STA, the reporting STA, or a third STA with the MAC address specified in the Target MAC Address field, by setting the Location Civic request Location Subject field to indicate a Local, a Remote, or a third-party request respectively. Local Location Civic request is used by requesting STA to obtain its own location by asking “Where am I?” Remote Location Civic request is used by requesting STA to obtain location of the reporting STA by asking “Where are you?” Third-party Location request is used by requesting STA to obtain location of a STA with the MAC address specified in the Target MAC Address field.

If dot11RMCivicMeasurementActivated is false, a STA that receives the received Location Civic request shall respond with a Location Civic report where the Incapable subfield is set in the Measurement Report Mode field.

If dot11RM3rdPartyMeasurementActivated is false, a STA shall reject any LCI request that includes an LCI request with the Location Subject field equal to 2 by returning a Radio Measurement Report frame including an Radio Measurement Report element with the Incapable subfield set to 1.

It is optional for a STA to support a Location Civic request and a Location Civic report with the Location Subject field equal to 2. If dot11RM3rdPartyMeasurementActivated is true and a STA supports Location Civic request and Location Civic report, the following procedure shall be followed:

— When a non-AP STA requests the civic location of a STA with the MAC address specified in the Target MAC Address field, it shall also include its own MAC address in the Originator Requesting STA MAC address field. When an AP receives a Location Civic request with the Location Subject field value equal to 2, the AP shall generate a Location Civic request to the STA with the MAC address specified in the Target MAC Address field. If the AP does not have an association with the STA with the MAC address specified in the Target MAC Address field, the AP shall reject the received Location Civic request by returning a Location Civic report where the Incapable subfield is set in the Measurement Report Mode field. The AP shall copy the Originator Requesting STA MAC address and Target MAC Address fields into the request from the received Location Civic request.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— When a STA receives a Location Civic request with the Location Subject field value equal to 2, the STA may generate a Location Civic report if the MAC address in the Target MAC Address field is its own MAC address; it shall not generate a Location Civic report otherwise. When a Location Civic report is generated, the reporting STA shall include its MAC address into the Target MAC Address field and the MAC address present in the Originator Requesting STA MAC address field of the corresponding Location Civic request into the Originator Requesting STA MAC address field. When an AP receives a Location Civic report with an Originator Requesting STA MAC address field present, the AP shall generate a Location Civic report to the associated STA with the MAC address specified in the Originator Requesting STA MAC address field. The AP shall copy the Originator Requesting STA MAC address and Target MAC Address fields into the Location Civic report being transmitted to the originating requesting STA.

When a STA receives a Location Civic request with the subject field equal to 2, but does not support third-party location, it shall respond with a Radio Measurement Report frame including a Radio Measurement Report element with the Incapable subfield set to 1.

If dot11RMCivicMeasurementActivated is true and a STA has its own location configured in civic format, excluding an unknown civic location as defined in 9.4.2.20.13, the STA shall set dot11RMCivicConfigured to true.

If dot11RMCivicMeasurementActivated is true and a STA has its own location available in one or more location formats, as defined in Table 9-154, and includes Civic Location Type field value 0, indicating “IETF RFC 4776,” it shall set the Civic Location field to 1 in the Extended Capabilities element.

NOTE—The Location Civic field’s size limit constrains the amount of information that can be carried.

If the Location Civic report contains the Location Reference and Location Shape subelements, the receiving STA may use the information specified in those subelements in combination with the Location Civic field value for additional granularity on the position reported in the Location Civic field.

If the Location Civic report contains the Map Image subelement, the receiving STA’s SME can retrieve the floor map specified by the Map URL field. The method to retrieve the floor map specified by the Map URL field is out of scope of this document. If the URL includes the floor map georegistration parameters s_lat, w_lng, n_lat and e_lng as query parameters then the receiving STA's SME can georeference the floor map.

For example, if the response to a Location Civic request with Location Subject field equal to Location Subject Local is a Location Civic report containing a Location Reference field equal to “Lobby Entrance”, a Location Shape ID field equal to 2-Dimension Point, a Location Shape Value field equal to (0, –1.5), a Map Type field equal to png, a Map URL field equal to “http://www.example.com/maps/exampleBuilding/lobbyLevel.png” (i.e., without floor map georegistration parameters) and a Map Registration subelement containing X Min = –50, Y Min = –100, Z Min = 0, X Max = 49.9, Y Max = 0, then a process related to the user interface might retrieve the map image and display it from (–50 m, –100 m) to (49.9 m, 0 m) , place a pin at (0 m, 0 m) labelled “Lobby Entrance”, and place a second pin at (0 m, –1.5 m) labelled “You Are Here”.

11.10.9.10 Location Identifier report

The Location Identifier report provides the ability for a STA to receive one or more:

— Indirect URI references and forward a subset of those references to an external agent for the purposes of that agent gathering the STA’s location value. The protocol used to query for a location report based on the Public Identifier URI/FQDN provided in the Location Identifier report is indicated by the URI/FQDN Descriptor field.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— FQDNs, one per location server, that can be used to discover the location server and establish communications with it. The protocol used with the location server is indicated by the URI/FQDN Descriptor field.

If dot11RMIdentifierMeasurementActivated is true and location information is not available, the STA that receives a Location Identifier request shall respond with a Radio Measurement Report frame including a Measurement Report element with the Incapable subfield set to 1. If dot11RMIdentifierMeasurementActivated is true and location information is available, the STA shall respond with a Radio Measurement Report frame including one Measurement Report element containing a Location Identifier report that carries one or more Public Identifier URI/FQDN subelements.

A Location Identifier request shall indicate a location request for the requesting STA, the reporting STA, or a third-party STA with the MAC address specified in the Target MAC Address field, by setting the Location Identifier request Location Subject field to indicate a Local, a Remote, or a Third-party request respectively. Local Location Identifier request is used by requesting STA to obtain its own location by asking “Where am I?” Remote Location Civic request is used by requesting STA to obtain location of the reporting STA by asking “Where are you?” Third-party Location request is used by requesting STA to obtain location of a STA with the MAC address specified in the Target MAC Address field.

If dot11RM3rdPartyMeasurementActivated is false, a STA that receives an LCI request that includes an LCI request with the Location Subject field equal to 2 shall respond with a Radio Measurement Report frame including an Radio Measurement Report element with the Incapable subfield set to 1.

It is optional for a STA to support a Location Identifier request and a Location Identifier report with the Location Subject field equal to 2. If dot11RM3rdPartyMeasurementActivated is true and a STA supports Location Identifier request and Location Identifier report, the following procedure shall be followed:

— When a non-AP STA requests the location identifier of a STA with the MAC address specified in the Target MAC Address field, it shall also include its own MAC address in the Originator Requesting STA MAC address field. When an AP receives a Location Identifier request with the Location Subject field value equal to 2, the AP shall generate a Location Identifier request to the STA with the MAC address specified in the Target MAC Address field. If the AP does not have an association with the STA with the MAC address specified in the Target MAC Address field, the AP shall reject the received Location Identifier request by returning a Location Identifier report where the Incapable subfield is set in the Measurement Report Mode field. The AP shall copy the Originator Requesting STA MAC address and Target MAC Address fields into the request from the received Location Identifier request.

— When a STA receives a Location Identifier request with the Location Subject field value equal to 2, the STA may generate a Location Identifier report if the MAC address in the Target MAC Address field is its own MAC address; it shall not generate a Location Identifier report otherwise. When a Location Identifier report is generated, the reporting STA shall include its MAC address into the Target MAC Address field and the MAC address present in the Originator Requesting STA MAC address field of the corresponding Location Identifier request into the Originator Requesting STA MAC address field. When an AP receives a Location Identifier report with an Originator Requesting STA MAC address field present, the AP shall generate a Location Identifier report to the associated STA with the MAC address specified in the Originator Requesting STA MAC address field. The AP shall copy the Originator Requesting STA MAC address and Target MAC Address fields into the Location Identifier report being transmitted to the originating requesting STA.

When a STA receives an Location Identifier request with the subject field equal to 2, but does not support third-party location, it shall respond with a Radio Measurement Report frame including a Radio Measurement Report element with the Incapable subfield set to 1.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If dot11RMIdentifierMeasurementActivated is false, a STA shall reject the received Location Identifier request by returning a Location Identifier report where the Incapable subfield is set in the Measurement Report Mode field.

If dot11RMIdentifierMeasurementActivated is true and a STA has its own location available in one or more location formats, as defined in Table 9-154, and includes Civic Location Type field value 0, indicating "IETF RFC 4776" or geospatial format that can be referenced by a location identifier, it shall set the Identifier Location field to 1 in the Extended Capabilities element.

11.10.9.11 FTM Range report

The FTM Range report provides a means for a requesting STA to request a responding STA that advertises FTM Range Report Capability Enabled equal to true in the RM Enabled Capabilities element to measure and report the ranges between the responding STA and other nearby APs where the ranges are determined using the FTM procedure (see 11.21.6).

If dot11RMFineTimingMsmtRangeRepActivated is true, dot11FineTimingMsmtInitActivated shall be true also.

If dot11RMFineTimingMsmtRangeRepActivated is false, a STA shall reject any FTM Range request by responding with a Radio Measurement Report frame that includes a Measurement Report element with the Incapable subfield set to 1.

If a responding STA with dot11RMFineTimingMsmtRangeRepActivated equal to true accepts an FTM Range request, then:

— If the request includes a maximum age subelement, and the STA has already determined FTM ranges to C APs listed in the Neighbor Report subelements in the Measurement Request field within the indicated Maximum Age, then the STA may use these ranges instead of initiating new FTM procedures with the C APs. Define C_{sub} as the subset of APs selected by the STA from the C eligible APs.

— Considering the remaining listed APs in the Neighbor Report subelements in the Measurement Request field, if Minimum AP Count exceeds C_{sub}, the responding STA shall wait a random delay up to the value of Randomization Interval field in the Measurement Request element (see 11.10.3) then initiate the FTM procedure with at least Minimum AP Count – C_{sub} remaining listed APs. The responding STA should initiate the FTM procedure with the remaining listed APs until either the responding STA has successfully measured the range between the responding STA with at least Minimum AP Count APs or has attempted the FTM procedure with all remaining listed APs. For each FTM procedure that is attempted with a remaining listed AP without success, the responding STA shall record an error entry.

  For procedures related to listed APs that operate on nonoperating channels, see 11.10.2.

  The responding STA shall transform the measurements obtained from each FTM procedure with an AP into a range and a maximum error between itself and the AP, while accounting for any clock offsets between the responding STA and the AP.

At the completion of all of the FTM procedures and transformations, the responding STA shall send the all computed range information between itself and other APs, and all error entries, to the requesting STA using a Measurement Report element with Measurement Type field set to FTM Range in a Radio Measurement Report frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A requesting STA may request a single set of range measurements by setting the Number of Repetitions field to 0 in the Radio Measurement Request frame, or request a regular sequence of range measurements by

— Setting the Number of Repetitions field greater than 0 in the Measurement Request frame, and
— Including a Measurement Request element with Measurement Type field equal to FTM Range and a Measurement Request element with Measurement Type field equal to Measurement Pause (see 11.10.9.7).

11.10.10 Usage of the neighbor report

11.10.10.1 General

A neighbor report is sent by an AP and it contains information on neighboring APs that are members of ESSs requested in the neighbor report request. A neighbor report might not be exhaustive either by choice, or due to the fact that there might be neighbor APs not known to the AP. The neighbor report contents are derived from the NeighborListSet parameter of the MLME-NEIGHBORREPRESP.request primitive. The mechanism by which the contents of this table are determined is outside the scope of this standard, but it may include information from measurement reports received from the STAs within the BSS, information obtained via a management interface, or information from the DS.

NOTE—The purpose of the neighbor report is to enable the STA to optimize aspects of neighbor service set transition and ESS operation. A Neighbor Report element contains information on APs that the STA might use as candidates for a service set transition. Since the information in the neighbor report might be stale, it is advisory; information obtained by the report recipient through a scan or other sources might also be considered, possibly overriding information in the neighbor report. For example, where information contained within a neighbor report is contradicted by information in a Measurement Pilot, Beacon, or Probe Response frame, that response information needs to take precedence.

An AP in which dot11RMNeighborReportActivated is false shall not transmit an FTM Range request. An AP in which dot11RMNeighborReportActivated is false should not transmit a Measurement Request with the Measurement Type field equal to LCI and the Location Subject field of the LCI request set to Location Subject Remote.

11.10.10.2 Requesting a neighbor report

A STA requesting a neighbor report from an AP shall send a Neighbor Report Request frame to its associated AP.

A STA can request LCI information of an AP and its neighboring APs, if the AP advertises the FTM responder capability (Extended Capabilities element with the FTM Responder field set to 1), the geospatial location capability (Extended Capabilities element with the Geospatial Location field set to 1), and the neighbor report capability (RM Enabled Capabilities element with the Neighbor Report Capability Enabled field set to 1). A STA can request civic location information of an AP and its neighboring APs, if the AP advertises the FTM responder capability (Extended Capabilities element with the FTM Responder field set to 1), the location civic capability (Extended Capabilities element with the Civic Location field set to 1), and the neighbor report capability (RM Enabled Capabilities element with the Neighbor Report Capability Enabled field set to 1).

To request the LCI of neighboring APs, the STA shall transmit a Neighbor Report Request frame that includes a Measurement Request element with the value of its Measurement Type field equal to LCI. To request the location civic of neighboring APs, the STA shall transmit a Neighbor Report Request frame that includes a Measurement Request element with the value of its Measurement Type field equal to Location Civic.

To request a list of neighboring APs that support DMG location services, the STA shall transmit a Neighbor Report Request frame that includes a Neighbor DMG request field with a Measurement Request element with the value of its Measurement Type field equal to Neighboring DMG APs. A STA shall not send this type of request to an AP unless it received an Extended Capabilities element from the AP with the DMG Location

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Supporting APs Information field equal to 1. The Neighbor Report Request frame shall include an SSID element with the SSID set to wildcard SSID.

11.10.10.3 Responding to a neighbor report request

If dot11RMNeighborReportActivated is true, an AP receiving a neighbor report request shall respond with a Neighbor Report Response frame containing zero or more Neighbor Report elements. If an SSID element is specified in the corresponding Neighbor Report Request frame, the Neighbor Report element(s) shall contain information only concerning neighbor APs that are members of the ESS identified by the SSID element contained within the neighbor report request. If the SSID element is omitted, the Neighbor Report element(s) shall contain information concerning neighbor APs that belong to the same ESS as the requesting STA. If the wildcard SSID element is specified in the corresponding Neighbor Request frame, the Neighbor Report element(s) shall contain information concerning all neighbor APs. If there are no neighbor APs available, the AP shall send a Neighbor Report Response frame with no Neighbor Report elements.

If dot11RMNeighborReportActivated is true and dot11FineTimingMsmtRespActivated is true, an AP receiving a neighbor report request shall respond with a Neighbor Report Response frame containing one or more Neighbor Report elements.

If dot11RMNeighborReportActivated is false in an AP receiving a neighbor report request, it shall ignore the request.

A serving AP shall include a TSF subelement in the Neighbor Report element if it is able to guarantee an accumulated error of 1.5 TU or better on the TSF Offset subfield. Otherwise, the AP shall not include a TSF subelement in the Neighbor Report element.

When the SSID element is omitted, the SSID element is specified by the wildcard SSID, or the SSID element is present and indicates the AP's own SSID and either of the following is true:

— An AP that has both dot11FineTimingMsmtRespActivated and dot11RMLCIConfigured equal to true receives a Measurement Request element with Measurement Type field equal to LCI

— An AP that has both dot11FineTimingMsmtRespActivated and dot11RMCivicConfigured equal to true receives a Measurement Request element with Measurement Type field equal to Location Civic

within a Neighbor Report Request frame, then the AP shall include a Neighbor Report element for the AP's own BSSID in the Neighbor Report Response frame (i.e., in this case the Neighbor Report Response frame contains one or more Neighbor Report elements). If dot11RMLCIConfigured is equal to true, the Neighbor Report element shall include a Measurement Report subelement with the Measurement Type field equal to LCI. If dot11RMCivicConfigured is equal to true, the Neighbor Report element shall include a Measurement Report sub element with the Measurement Type field equal to Location Civic.

When both of the following are true:

— The SSID element specified in the Neighbor Report Request does not include the AP's own SSID and an AP that has at least one of dot11FineTimingMsmtRespActivated and dot11RMLCIConfigured equal to false receives a Measurement Request element with the Measurement Type field equal to LCI within a Neighbor Report Request frame

— An AP that has at least one of dot11LciCivicInNeighborReport and dot11RMLCIConfigured equal to false receives a Neighbor Report Request frame

then the AP shall not include a Neighbor Report element containing a Measurement Report subelement with the Measurement Type field set to LCI describing the reporting AP in the Neighbor Report Response frame. In this case the Neighbor Report Response frame contains zero or more Neighbor Report elements.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When both of the following are true:

— The SSID element specified in the Neighbor Report request does not include the AP's own SSID and an AP that has at least one of dot11FineTimingMsmtRespActivated and dot11RMCivicConfigured equal to false receives a Measurement Request element with the Measurement Type field equal to Location Civic within a Neighbor Report Request frame

— An AP that has at least one of dot11LciCivicInNeighborReport and dot11RMCivicConfigured equal to false receives a Neighbor Report Request frame

then the AP shall not include a Neighbor Report element containing a Measurement Report subelement with Measurement Type set to Location Civic describing the reporting AP in the Neighbor Report Response frame (i.e., in this case the Neighbor Report Response frame contains zero or more Neighbor Report elements). In this case the Neighbor Report Response frame contains zero or more Neighbor Report elements.

NOTE—The Neighbor Report Response frame includes a list of Neighbor Report elements one for each neighbor. The criteria for the selection of an AP as a neighbor AP is beyond the scope of this standard.

The Neighbor Report Response frame shall also include a Neighbor Report element for each neighbor AP.

When either of the following is true in a neighbor AP of the AP (reporting AP) that receives a Measurement Request element with the Measurement Type field equal to LCI within a Neighbor Report Request frame:

— The neighbor AP has both FTM responder capability (Extended Capabilities element with the FTM Responder field set to 1) and LCI measurement capability (RM Enabled Capabilities element with the LCI Measurement Capability Enabled field set to 1)

— The reporting AP has dot11LciCivicInNeighborReport equal to true and the neighbor AP has LCI measurement capability (RM Enabled Capabilities element with the LCI Measurement Capability Enabled field set to 1)

then the reporting AP shall include a Neighbor Report element in the Neighbor Report Response frame. In addition if the neighbor AP has geospatial location capability (Extended Capabilities element with the Geospatial Location field set to 1), the Neighbor Report element shall include a Measurement Report subelement with Measurement Type equal to LCI. If the maximum horizontal or vertical location error of the neighbor AP relative to a reference AP is known to the AP and this relative error is smaller than the absolute error indicated in the LCI subelement, then the AP may include a Relative Location Error subfield in the Measurement Report field.

When either of the following is true in a neighbor AP of the AP (reporting AP) that receives a Measurement Request element with the Measurement Type equal to Location Civic within a Neighbor Report Request frame:

— The neighbor AP has both FTM responder capability (Extended Capabilities element with the FTM Responder field set to 1) and civic location measurement capability (RM Enabled Capabilities element with Civic Location Measurement Capability Enabled set to 1)

— The reporting AP has dot11LciCivicInNeighborReport equal to true and the neighbor AP has civic location measurement capability (RM Enabled Capabilities element with Civic Location Measurement Capability Enabled set to 1)

then the reporting AP shall include a Neighbor Report element in the Neighbor Report Response frame. In addition if the neighbor AP has Civic Location (Extended Capabilities element with the Civic Location field set to 1), the Neighbor Report element shall include a Measurement Report subelement with the Measurement Type field equal to Location Civic.

Each Measurement Report subelement returned shall have the same Measurement Token value as in the Measurement Token field of the corresponding Measurement Request element, or if there is no corresponding Measurement Request then the Measurement Token value shall be set to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If an AP determines that the LCI and/or civic location of a neighboring AP changes, the AP may send an unsolicited Neighbor Report Response frame containing complete neighbor information including the updated neighboring AP location information. The Dialog Token field is set to 0 as defined in 9.6.6.7.

A STA that receives an LCI report that contains a Usage Rules/Policy subelement shall process the LCI information in compliance with the retransmission and retention permissions in the Usage-rules subelement.

The Wide Bandwidth Channel subelement shall not be included in the Neighbor Report element when either the HT Operation subelement or the VHT Operation subelement is included in the Neighbor Report element.

A VHT AP in which dot11FineTimingMsmtRespActivated is true that transmits a Neighbor Report element containing an HT Operation subelement shall include a VHT Operation subelement in the Neighbor Report element.

A non-DMG AP in which dot11FineTimingMsmtRespActivated is true that transmits a Neighbor Report element containing neither an HT Operation subelement nor a VHT Operation subelement shall include a Wide Bandwidth Channel subelement in the Neighbor Report element.

An AP that has set the DMG/Location Supporting APs In The Area field to 1 in the Extended Capabilities element that receives a Neighbor Report Request frame that includes a Measurement Request element with the value of its Measurement Type field equal to Neighboring DMG APs, shall respond with a Neighbor Report Measurement frame with a list of Neighbor Report elements of neighboring DMG APs supporting location services. Per each DMG AP, the Neighbor Report element shall include a Measurement Report subelement with the Measurement Type field equal to LCI. If available to the sending AP, the Neighbor Report element shall include a TSF subelement. The definition of which APs are neighboring APs is implementation dependent. If the AP sending is collocated with a DMG AP that is location capable, the collocated DMG AP should be included in the list.

11.10.11 Link measurement

A STA may use a Link Measurement Request frame to request another STA to respond with a Link Measurement Report frame containing a TPC report element. If dot11RMLinkMeasurementActivated is true, a STA receiving a Link Measurement Request frame shall respond with a Link Measurement Report frame containing a TPC Report element indicating the power used to transmit the Link Measurement report. The Link Measurement report also contains antenna ID or DMG antenna ID and signal quality (RCPI and RSNI).

If dot11RMLinkMeasurementActivated is false in an AP or PCP receiving a Link Measurement Request, it shall ignore the request.

11.10.12 Measurement of the RPI histogram

To compute RPI densities for an RPI Histogram report (see 9.4.2.20.4), the STA shall measure the received power level on the specified channel, as detected at the antenna connector, as a function of time over the measurement duration. The tolerance of the received power measurements shall be ± 5 dB. Furthermore, the received signal power measurement should be a monotonic function of the actual power at the antenna connector. The time resolution of the received power measurements is in microseconds. The received power measurements are converted to a sequence of RPI values by quantizing the measurements according to Table 9-164. The RPI densities are then computed for each of the eight possible RPI values using

$$\text{RPI Density} = \left\lceil \frac{255 \times D_{RPI}}{1024 \times D_M} \right\rceil$$

where

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

D_{RPI} is the duration receiving at the specified RPI value (μs)
D_M is the measurement duration (TU)

The sum of the RPI densities is approximately 255, but could be up to 262 because of rounding effects.

11.10.13 Operation of the Max Transmit Power field

The Max Transmit Power field shall be less than or equal to the Max Regulatory Power value for the current channel.

11.10.14 Multiple BSSID set

A multiple BSSID set is characterized as follows:

— All members of the set use a common operating class, channel, channel access functions, receive antenna connector, and transmit antenna connector.
— The size of the set is 2^n, for a selected value of n:
  — $1 \le n \le 8$ if dot11MultiBSSIDImplemented is true.
  — $1 \le n \le 46$ if dot11MultiBSSIDImplemented (if present) is false and dot11RMMeasurementPilotActivated is nonzero.
— All BSSIDs within the multiple BSSID set are assigned in a way that they are not available as MAC addresses for STAs using a different operating class, channel, receive antenna connector, or transmit antenna connector.

NOTE—For example, if the APs within BSSs with BSSIDs 16, 17, and 27 share the same operating class, channel, receive antenna connector, and transmit antenna connector, and the range of MAC addresses from 16 to 31 inclusive is are not assigned to other STAs using a different receive antenna connector or transmit antenna connector, then the BSSIDs 16, 17, and 27 are members of a multiple BSSID set. The set is described by $n = 4$ ($2^n = 16$) with BSSIDs in the range 16–31. The set cannot be described by $n = 8$ for instance since at least one of the BSSIDs in the range 0–255 might be used as a BSSID by an AP that does not share the same operating class, channel, receive antenna connector, and transmit antenna connector.

When the multiple BSSID set contains two or more members, the transmission of Measurement Pilot frames is constrained as described in 11.10.15.

A Multiple BSSID element, with or without optional subelements, indicates that all APs and PCPs within the indicated range of BSSIDs transmit using a common class, channel, and antenna connector.

A single Beacon frame may contain elements for the multiple BSSID set members; see 11.1.3.8.

11.10.15 Measurement Pilot frame generation and usage

11.10.15.1 General

The Measurement Pilot frame is a compact Action frame transmitted pseudo-periodically by an AP at a small interval relative to a Beacon Interval. The Measurement Pilot frame provides reduced information relative to a Beacon frame to allow for the required small interval. The purpose of the Measurement Pilot frame is to assist a STA with the following functions:

— Rapid discovery of the existence of a BSS via passive scanning
— Rapid collection of neighbor AP signal strength measurements via passive scanning
— Enable transmission of a Probe Request frame

A STA's dot11RMMeasurementPilotActivated determines the level of support for measurement pilot at the STA. Table 11-14 describes permitted values for dot11RMMeasurementPilotActivated and what they signify.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table 11-14—Measurement pilot activated definition

Device function	dot11RM-MeasurementPilot Activated	Notes
AP and non-AP STA	0	If the STA is contained within an AP, it does not generate MPs and if the device is a non-AP STA, it ignores the MPs it receives
AP and non-AP STA	1	If the STA is contained within an AP, it can transmit MPs, and if the device is a non-AP STA, it can receive the MPs and can use the information contained in MPs.
Non-AP STA	2	The non-AP STA is making use of the MPs it receives or would receive if they were being transmitted.
Non-AP STA	3–7	Reserved
AP		The AP is transmitting MPs and using the information contained in them, and the AP is transmitting MPs with MP interval set to a value within the range as shown below. MP Interval with respect to Beacon Interval:
	2	> 3% and < 5% of Beacon Interval
	3	≥ 5% and < 10%
	4	≥ 10% and < 15%
	5	≥ 15% and < 20%
	6	≥ 20% and < 25%
	7	≥ 25% and < 50%

11.10.15.2 Measurement Pilot frame generation by an AP

The AP shall determine if it is a member of a multiple BSSID set with two or more members. If so, at most one AP of the multiple BSSID set shall have dot11RMMeasurementPilotActivated set to a value between 2 and 7. How this occurs is out of scope of this standard.

If dot11MultiBSSIDImplemented is false and dot11RMMeasurementPilotActivated is between 2 and 7, the following statements apply:

— If the AP is a member of a multiple BSSID set with two or more members, then the BSSIDs of all members of the multiple BSSID set shall be indicated in the Beacon and Probe Response frames by the Multiple BSSID subelement.

— The AP shall maintain a Measurement Pilot frame generation function, which transmits Measurement Pilot frames at a basic rate according to dot11RMMeasurementPilotPeriod.

— The AP defines a series of TMPTTs exactly dot11RMMeasurementPilotPeriod apart. A TMPTT arrives when the AP's local TSF timer (in μs) modulo the measurement pilot interval equals 0.

— At each TMPTT, the AP shall schedule a Measurement Pilot frame as the next frame for transmission ahead of other queued frames using the AC_VO EDCA parameters unless the TMPTT satisfies:

$$\text{TBTT} - \frac{T_{MPP}}{2} \leq \text{TMPTT} < \text{TBTT} + \frac{T_{MPP}}{2}$$

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

where T_{MPP} is dot11RMMeasurementPilotPeriod, for any TBTT of members of the multiple BSSID set, in which case the AP shall not generate the Measurement Pilot frame. This is illustrated in Figure 11-35 . How the AP determines the TBTTs of members of the multiple BSSID set is out of scope of this standard.

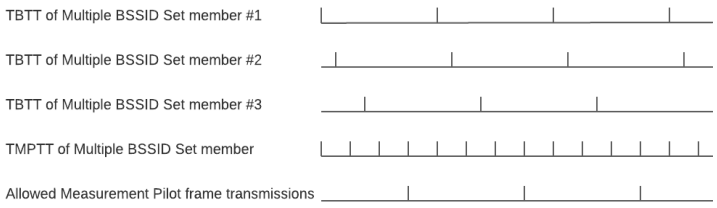

Figure 11-35—Example of Measurement Pilot frame scheduling

In case the medium is determined by the carrier-sense mechanism (see 10.3.2.1) to be unavailable at the TMPTT, the AP shall delay the actual transmission of a Measurement Pilot frame according to the basic medium access rules specified in Clause 10 for a maximum period of one dot11RMMeasurementPilotPeriod and discard the delayed Measurement Pilot frame at the next TMPTT. In this way, a continuously busy medium causes multiple successive Measurement Pilot frames to be delayed, then discarded. An AP shall transmit Measurement Pilot frames to the broadcast address. An AP shall not retransmit or buffer Measurement Pilot frames as part of the PSP mechanisms.

— If the AP is a member of a multiple BSSID set with two or more members, then the BSSIDs of all members of the multiple BSSID set shall be indicated in the Measurement Pilot frame using the Multiple BSSID subelement.

NOTE 1—APs are advised to enable Measurement Pilot frames judiciously due to the possibility of excessive medium time being consumed by Measurement Pilot frames from multiple overlapping APs. For instance dot11RMMeasurementPilotTransmissionInformationActivated might be set to false:

a) When enabling Measurement Pilot frames would cause:
   1) More than 10% of the medium time at the AP to be consumed by beacons and Measurement Pilot frames transmitted by any source, or
   2) More than 5% of the medium time at the AP to be consumed by Measurement Pilot frames transmitted by any source.
b) When STAs are not expected to be using Measurement Pilot frames. How this is determined is out of the scope of this standard, but may depend upon many STAs setting the Measurement Pilot Capability field in the RM Enabled Capabilities element to 0 or 1 upon association at any member of the multiple BSSID set recently or at similar times in the past.
c) When all members of the multiple BSSID set are within ESSs that contain one BSS only.
d) When the AP's operating regulatory domain is not subject to DFS regulations.
e) When the AP's operating regulatory domain is subject to DFS regulations but compliance with the regulations is impaired by Measurement Pilot frames.
f) When the number of channels valid for the AP's operating regulatory domain or frequency band is small.
g) When no members of the multiple BSSID set are located at ingress or egress points of an ESS, so are less useful for roaming between an IEEE 802.11 ESS and other networks.

NOTE 2—For efficient use of the medium, it is recommended that Measurement Pilot frames not be sent using a PHY specified in Clause 15 or Clause 16.

An AP that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Measurement Pilot frame. If the Wide Bandwidth Channel Switch subelement is included in a Measurement Pilot frame, then the Operating Class shall include a 40 MHz channel spacing.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.10.15.3 Measurement pilot usage by a STA

Whenever testing a requested BSSID for equality against the BSSID field of a Measurement Pilot frame, the following statements apply:

— If the Measurement Pilot frame does not contain the Multiple BSSID element, then equality shall be true if the requested BSSID equals the BSSID field of the Measurement Pilot frame, and otherwise false.

— If the Measurement Pilot frame contains the Multiple BSSID element, and the requested BSSID is a non-wildcard BSSID, then equality shall be true if the requested BSSID equals any BSSID indicated by the Multiple BSSID element present in the Measurement Pilot frame, and otherwise false.

— If the Measurement Pilot frame contains the Multiple BSSID element, and the requested BSSID is the wildcard BSSID, then equality shall be true.

NOTE—STAs are advised that due to considerations such as those noted in the prior subclause, APs might not transmit Measurement Pilot frames at all times or in all bands.

11.10.16 Access delay measurement

Access delay is measured by the AP's or PCP's MAC being the average medium access delay for transmitted frames measured from the time the MPDU is ready for transmission (i.e., begins CSMA/CA access or SP access, as appropriate) until the actual frame transmission start time. Access delay measurement results are included in the BSS Average Delay element and in the BSS AC Access Delay element.

For the BSS Average Delay measurement, the AP or PCP shall measure and average the medium access delay for all transmit frames using the DCF or EDCAF over a continuous 30 s measurement window. For the infrastructure BSS AC Access Delay measurement, the QoS AP or PCP shall measure and average the medium access delay for all transmit frames of the indicated AC (see Figure 9-429) using EDCA mechanism over a continuous 30 s measurement window. The accuracy for the average medium access delay shall be ± 100 μs or better when averaged over at least 200 frames. Accuracy is not defined for measurements averaged over less than 200 frames.

11.10.17 BSS Available Admission Capacity

BSS Available Admission Capacity provides a means for an AP to advertise admission capacity available for explicit admission control in any UP or AC. This information may assist STAs in making service set transition decisions.

The transmitted BSS Available Admission Capacity value represents a proportion of time on the wireless medium scaled linearly in units of 32 μs/s from 0 (0% available time) to 31 250 (100% available time). If an AP transmits a BSS Load element, the values for any transmitted BSS Available Admission Capacity values shall be less than or equal to the Available Admission Capacity field of the BSS Load element. If an AP transmits a BSS Available Admission Capacity element, the transmitted values should be current or recently calculated. The AP recalculates Available Admission Capacity values according to local policy. An Available Admission Capacity value of 0 transmitted in the BSS Available Admission Capacity element indicates that no admission capacity is available at the calculation time and that no explicit admissions can be granted by the AP for that UP or AC unless additional capacity becomes available. An AP that receives a TSPEC admission request for total medium time (in both directions, if applicable) that is less than or equal to the current available admission capacity for the requested UP or AC local policy may apply additional local policy before admitting the requested TSPEC.

NOTE 1—Available Admission Capacity values are dynamic in a BSS and the transmitted values cannot always reflect the actual values currently used by the AP for explicit admission control. Thus an AP should recalculate the Available Admission Capacity values regularly or after changes in the environment or the admitted capacity.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 2—STAs are advised that requesting admission for any TSPEC at an UP or AC that requires more medium time than is reported as available for the requested UP or AC is possible yet unlikely to be successful.

11.10.18 AP Channel Report

The AP Channel Report element contains a list of channels in an operating class where a STA is likely to receive the Beacon or Probe Response frames sent by an AP, excluding the AP transmitting the AP Channel report. An AP Channel Report element only includes channels that are valid for the regulatory domain in which the AP transmitting the element is operating and consistent with the Country element in the frame in which it appears. One AP Channel Report element is included in the Beacon frame for each regulatory domain, which includes channels on which a STA is likely to receive the Beacon or Probe Response frames sent by an AP.

The contents of the AP Channel Report elements may be compiled from the list of unique operating/channel pairs found in the neighbor report. The contents of the AP channel report may be configured or obtained by other means beyond the scope of this standard.

11.10.19 Multicast diagnostic reporting

Multicast diagnostic reporting enables an AP to collect statistics on group addressed traffic at associated STAs. The method an AP uses to determine the multicast groups to which an associated STA is a member of is outside the scope of the standard and is typically performed by higher layer protocols. The Multicast Diagnostic request and Multicast Diagnostic report are defined in 9.4.2.19.13 and 9.4.2.20.12, respectively.

A STA with dot11MulticastDiagnosticsActivated equal to true shall support multicast diagnostics reporting and shall set to 1 the Multicast Diagnostics field of the Extended Capabilities elements that it transmits. When the Multicast Diagnostics field in the Extended Capabilities field is 1, the Incapable subfield in the Measurement Report Mode field of a Multicast Diagnostic report shall not be set to 1.

Multicast diagnostic reporting may use the triggered autonomous reporting capability described in 11.10.8.

The Measurement Start Time field of a triggered diagnostic report shall contain the value of the STA TSF Timer at the time the trigger condition started to occur to an accuracy of ± 1 TU.

An AP may send a Multicast Diagnostic request consisting of one or more Multicast Diagnostic requests in a Radio Measurement Request frame to a non-AP STA that has indicated support of the multicast diagnostic capability or to a multicast-group address if all associated non-AP STAs support the multicast diagnostic capability. If the STA accepts the request it shall count the number of received MSDUs with the specified group address and the STA shall record the maximum observed PHY data rate of the frames that contained these MSDUs during the requested Measurement Duration. These two values shall be returned in a Multicast Diagnostic report in a Radio Measurement Report frame, as defined in 9.4.2.20.12. A non-AP STA shall not transmit a Radio Measurement Request frame containing a Multicast Diagnostic request. A STA shall not respond to a Radio Measurement Request frame containing a Multicast Diagnostic request received from a STA other than the AP with which it is associated.

An AP may request that triggered multicast diagnostic reporting be enabled at associated non-AP STAs that have indicated support of the multicast diagnostic capability. To enable multicast diagnostic reporting, the AP shall send a Measurement Request element containing the Request Type field set to Multicast Diagnostics and with the Enable and Report subfields set to 1 within a Radio Measurement Request frame. See 11.10.8. For triggered multicast diagnostic reporting, the Multicast MAC Address and trigger conditions for diagnostic reporting shall be specified in the request.

Multicast diagnostic reporting may be requested for broadcast traffic by setting the Multicast MAC Address field to the broadcast address.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A non-AP STA accepting a request for triggered multicast diagnostic reporting shall send a Multicast Diagnostics report to the requesting STA if the specified trigger condition occurs. The measuring non-AP STA shall not send further triggered Multicast Diagnostics reports until the period specified in the Reactivation Delay field in the Multicast Diagnostic Request has expired, or the non-AP STA receives a revised trigger condition from a Multicast Diagnostic Request. To prevent generation of too many triggered reports, the Reactivation Delay field shall be set to a value greater or equal to A STA's MinTriggerTimeout.

Once accepted, Multicast Diagnostic reporting continues to be active for the specified Multicast MAC address until one of the following occurs:

— The STA receives a Measurement Request element containing a Multicast Diagnostic Request Type and with the Enable subfield equal to 1 and the Report subfield equal to 0 within a Radio Measurement Request frame.
— Receipt of a Measurement Request element containing a Multicast Diagnostic Request Type, with the Enable and Report subfields equal to 1, but with no trigger conditions.
— The STA leaves the multicast group or disassociates.
— The STA sends a Measurement Report element with the Measurement Result bit set to 1.

The STA shall maintain an inactivity timer for every multicast diagnostic request accepted by the STA in which the Inactivity Timeout Request field is 1. When a timeout of the inactivity timer is detected, the STA shall send a multicast diagnostic report with the inactivity Timeout Trigger field in the Multicast Reporting Reason field set to 1. The inactivity timer at a recipient is reset when MSDUs corresponding to the monitored group address are received.

A STA that declines a request for triggered multicast diagnostic reporting sends a Measurement Report element (as described in 9.4.2.20) in a Radio Measurement Report frame (as described in 9.6.2.3) with the Measurement Report Mode field set appropriately to indicate the reason for a failed or rejected request.

11.10.20 CCA request and report

The response to a CCA request is a CCA report. A STA may support the generation of a CCA report. A STA may generate a CCA report in response to a CCA request.

11.10.21 RPI Histogram request and report

The response to an RPI Histogram request is an RPI histogram report. A STA may support the generation of an RPI histogram. A STA may generate an RPI histogram report in response to an RPI Histogram request.

11.11 DSE procedures

11.11.1 General

Regulations that apply to the United States and its territories 3650 MHz band require enabling STAs to implement a mechanism to enable mobile and portable STA operation. Similar regulations exist in other regulatory domains. This standard describes such a mechanism, referred to as *dependent STA enablement (DSE)*.

Regulations that apply to the United States and its territories 3650 MHz band require fixed STAs and enabling STAs to have their operating locations registered. Licensees with STAs suffering or causing harmful interference are expected to cooperate and resolve problems by mutually satisfactory arrangements. The DSE procedures provide the location of the enabling STA and unique identifiers to assist licensees in the resolution of interference issues. The DSE procedures might also satisfy needs in other frequency bands and be useful for other purposes.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA shall use the DSE procedures defined in this subclause if dot11LCIDSERequired is true. dot11DSERequired and dot11ExtendedChannelSwitchActivated shall be true when regulatory authorities require DSE, with the following exceptions: dot11DSERequired shall be set to false to configure STAs to operate as registered STAs, and dot11ExtendedChannelSwitchActivated may be set to false when operating as a fixed STA. A summary of STA attributes and these MIB attributes are shown in Table 11-15.

Table 11-15—DSE STA attributes

Type of STA	Registered STA	dot11LCIDSERequired and dot11LCIDSEImplemented	dot11ExtendedChannelSwitchActivated	dot11DSERequired
Fixed STA	Yes	true	true or false	false
Enabling STA	Yes	true	true	false
Dependent STA	No	true	true	true

A fixed STA is a registered STA that broadcasts its registered location and is restricted from enabling other STAs (see 11.11.3). An enabling STA is a registered STA that broadcasts its registered location, and regulatory authorities permit it to enable operation of unregistered STAs (see 11.11.4). A dependent STA is an unregistered STA that operates under the control of an enabling STA (see 11.11.5). When management frame protection is negotiated, stations shall use Protected Dual of Public Action frames instead of individually addressed Public Action frames for DSE procedures.

The DSE procedures provide for the following:

— Registered STA operation
— Creation of a DSE service area for dependent STA operation
— Dependent STA operation with DSE

11.11.2 Enablement and deenablement

11.11.2.1 General

This subclause describes the procedures used for IEEE 802.11 enablement and deenablement. A STA keeps a state variable for each STA with which enablement communication is needed:

— Enablement state with a value of *unenabled* or
— Enablement state with a value of *enabled*

NOTE—Refer to 11.11.5 for description of dependent STA operation in either enablement state.

Enablement utilizes a two-frame transaction sequence. The first frame asserts identity and requests enablement. The second frame returns the enablement result. In the description in 11.11.2.2 and 11.11.2.3, the STA initiating the enablement is referred to as *enablement requester*, and the STA to which the initial frame in the exchange is addressed is referred to as *enablement responder*. The specific items in each of the frames described in the following subclauses are defined in 9.6.7.4 and 9.6.7.5. An enabling STA may decline to enable a requesting STA. If the result is “successful,” the requesting STA shall be enabled.

Deenablement utilizes a one-frame transaction sequence. In the description in 11.11.2.4 and 11.11.2.5, the STA initiating the deenablement is referred to as *deenablement requester*, and the STA to which the frame is addressed is referred to as *deenablement responder*.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.11.2.2 Enablement requester STA

Upon receipt of an MLME-ENABLEMENT.request primitive, the enablement requester STA shall perform the following procedure:

a) Construct and transmit a DSE Enablement frame requesting enablement.
   1) Specific information items in the enablement frame are as follows.
      i) STA identity assertion (in RequesterSTAAddress)
      ii) Enabling STA identity assertion (in ResponderSTAAddress)
      iii) Reason result code = 2
      iv) Enablement identifier = 0
   2) Specific items in the enablement frame sent by the enablement responder STA are described in 11.11.2.3.

b) On receipt of a matching DSE Enablement frame (i.e., the Requester STA Address and Responder STA Address match the pending request) that acknowledges the DSE Enablement frame, issue an MLME-ENABLEMENT.confirm primitive to inform the SME of the result of the enablement.
   1) The primitive may contain information from an DSE Enablement frame received from the enabling STA (see 11.11.2.3), or it may be issued for another reason (see 9.6.7.4).
   2) The reason result code in the enablement confirmation frame indicates when the enablement is successful.
   3) If the enablement was successful, the enablement state variable for the enablement responder STA shall be set to Enabled.

c) If no matching DSE Enablement frame is received for the DSE Enablement frame within a period of EnablementTimeLimit TUs measured from the receipt of the MLME-ENABLEMENT.request primitive, issue an MLME-ENABLEMENT.confirm primitive with ResultCode set to TIMEOUT.

11.11.2.3 Enablement responder STA

Upon receipt of a Public Action DSE Enablement frame with a reason result code of 2, the enablement responder STA may enable the enablement requester STA using the following procedure:

a) Create and transmit a response frame with the enablement status as defined in 9.6.7.4 set in the Reason Result Code field and with a dependent enablement identifier chosen to be unique among all dependent enablement identifiers that have been assigned if enablement was successful. The enablement responder shall transmit the ResultCode parameter from the .confirm primitive mapped as specified in Table 9-474 of 9.6.7.4 to indicate the result of the enablement request.
   1) Specific information items in the enablement frame response are as follows:
      i) STA identity assertion (in RequesterSTAAddress)
      ii) Enabling STA identity assertion (in ResponderSTAAddress)
      iii) The result of the requested enablement as defined in 9.6.7.4
      iv) Enablement identifier

b) Issue an MLME-ENABLEMENT.indication primitive to inform the SME of the enablement.
   1) If the enablement is successful, the enablement state variable for the enablement requester STA shall be set to Enabled.

11.11.2.4 Deenablement requester STA

Upon receipt of an MLME-DEENABLEMENT.request primitive, the deenablement requester STA shall create and transmit a DSE Deenablement frame to the deenablement responder STA. Specific information items in the deenablement frame are as follows:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

a) Enabling STA identity assertion (in RequesterSTAAddress)
b) STA identity assertion (in ResponderSTAAddress)
c) Reason result code = 2

11.11.2.5 Deenablement responder STA

Upon receipt of a DSE Deenablement frame, the deenablement responder STA shall deenable with the deenablement requester STA by issuing an MLME-DEENABLEMENT.indication primitive to inform the SME of the deenablement. The enablement state variable for the deenablement requester STA shall be set to Unenabled.

11.11.3 Registered STA operation

A registered STA shall have dot11DSERequired equal to false. They shall transmit the DSE Registered Location element in every Beacon frame and shall set the Dependent STA subfield in the DSE Registered Location element to 0. If the registered STA is located within a national policy area, such as a Fixed Satellite Service exclusion zone, or within an international agreement area near a national border, the RegLoc Agreement subfield in the DSE Registered Location element shall be set to 1, signifying to other STAs that additional restrictions on STAs with directional antennas may apply; otherwise, it shall be set to 0.

The Latitude, Longitude, and Altitude fields of the DSE Registered Location element shall be reported at their best known resolutions, which might exceed the resolutions required by regulatory authorities. The Altitude Type field value shall be 3 (i.e., height above ground is in meters, unless another altitude type is required for operation in the regulatory domain. The Datum field value shall be 1 (World Geodetic System 1984), unless another datum is required for operation in the regulatory domain.

An enabling STA is a registered STA that broadcasts its registered location, and regulatory authorities permit it to enable operation of unregistered STAs (see 11.11.4). A dependent STA is an unregistered STA that operates under the control of an enabling STA (see 11.11.5).

A fixed STA is a registered STA that broadcasts its registered location and is restricted from enabling other STAs. A fixed STA shall have dot11LCIDSERequired set to true, and dot11ExtendedChannelSwitchActivated may be true or false. A fixed STA shall set dot11RegLocDSE to false and the RegLoc DSE subfield in the DSE Registered Location element to 0, signifying that it is not creating a DSE service area. A fixed STA may operate in an infrastructure BSS or IBSS. A registered STA that is not an enabling STA may operate as an AP and relay Public Action frames (specifically, DSE Enablement, DSE Deenablement, DSE Measurement Request, DSE Measurement Report, DSE Power Constraint) from a dependent STA to its enabling STA. The specification of the algorithm by which Public Action frames are relayed is beyond the scope of this standard. Note that the enabling signal is not a Public Action frame and is not relayed (see 11.11.4).

11.11.4 Enabling STA operation with DSE

A registered STA may create and manage a DSE service area for dependent STA operation where regulatory requirements permit. A registered STA operating in this manner is referred to as an *enabling STA*. An enabling STA shall set dot11RegLocDSE to true and shall signify the creation of a DSE service area by setting the RegLoc DSE subfield in the DSE Registered Location element to 1. Dependent STA transmission of any frames is conditional on receiving directly over the air and decoding a DSE Registered Location element with RegLoc DSE subfield equal to 1, sent from an enabling STA. Before attempting enablement with any one enabling STA, a dependent STA may have detected several enabling STAs, may attempt enablement with one and fail, and then attempt enablement with another. An enabling STA shall assign dependent enablement identifiers in a way that makes them unique among STAs enabled by this enabling STA to help identify sources of interference.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An enabling STA may issue a DSE measurement request to any of its dependent STAs in order to receive a DSE measurement report that may have reported DSE LCI fields received from nearby STAs. The licensed operator may be able to use these reports to identify interfering STAs or map overlapping coverage in a multiple BSS situation. Because reported DSE LCI fields may refer to any destination address, a single DSE report may contain elements received from STAs that are not yet associated with a BSS.

An enabling STA may issue an ECS announcement to any of its dependent STAs in order to have their radio operation changed in frequency, channel bandwidth, and other operational parameters. A dependent AP or DFS owner with dot11DSERequired true and receiving an ECS announcement from its enabling STA shall perform the extended channel switching procedure as specified in 11.9.

An enabling STA may issue a DSE power constraint announcement to any of its dependent STAs in order to have their transmit power reduced from the regulatory limit. A dependent AP or DFS owner with dot11DSERequired true and receiving a DSE power constraint announcement from its enabling STA shall perform the power constraint procedure as specified in 11.11.5.

11.11.5 Dependent STA operation with DSE

A dependent STA shall set dot11DSERequired to true.

A typical state machine implementation of dependent STA operation with DSE is provided in Figure 11-36 .

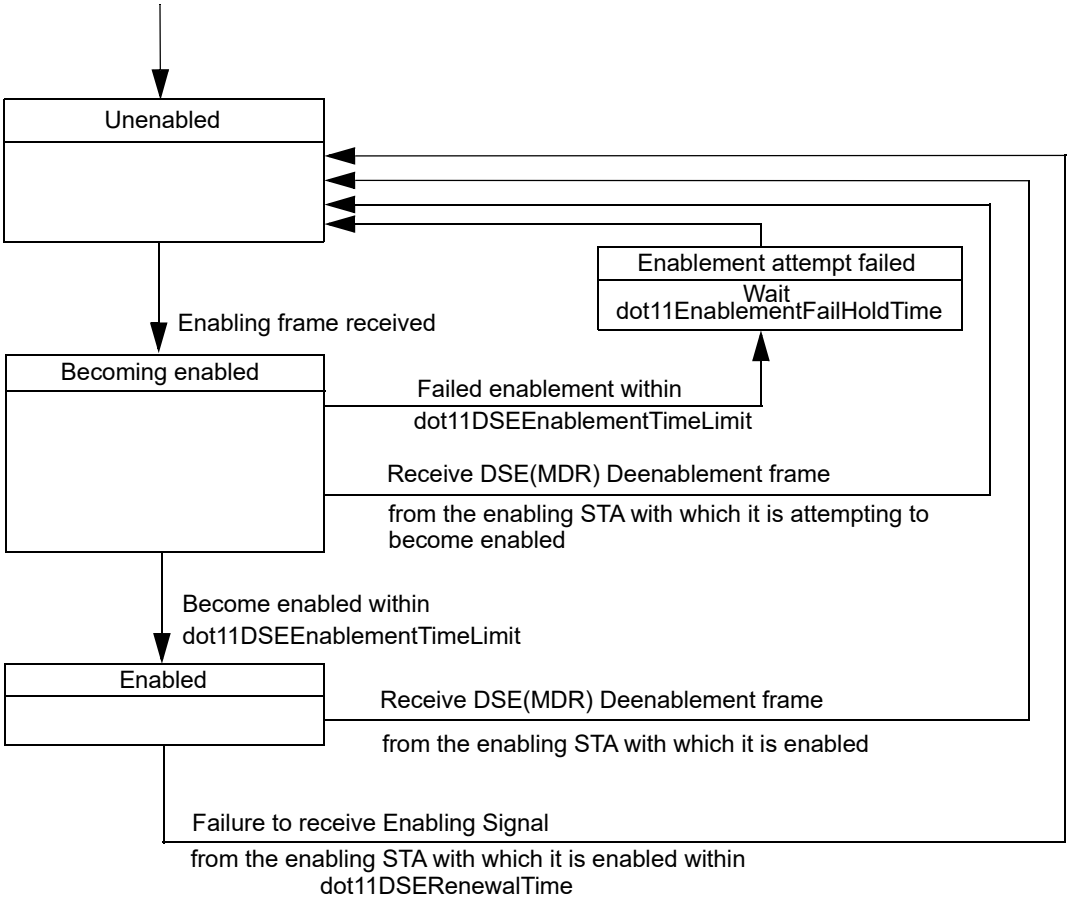

Figure 11-36—Dependent STA state machine

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

For DSE, the following statements apply:

- A STA with dot11DSERequired true shall not transmit any frames unless it has received a Beacon frame from an enabling STA with the Spectrum Management bit equal to 1 in the Capability Information field and with the RegLoc DSE subfield equal to 1 in the DSE Registered Location element. A dependent STA that is not enabled shall not transmit, except to attain enablement with an enabling STA, unless such action is mandated to be allowed in the regulatory domain (e.g., emergency services).
- A dependent STA shall not attempt enablement with an enabling STA unless the enabling STA is transmitting Beacon frames with the RegLoc DSE subfield equal to 1 in the DSE Registered Location element.
- A dependent STA creates a dependent DSE Registered Location element containing the enabling STA's DSE Registered Location element and having the RegLoc DSE subfield set to 0 and the Dependent STA subfield set to 1. Before enablement, the Dependent Enablement Identifier field shall be set to 0. Upon attaining enablement, the Dependent Enablement Identifier field shall be set to the dependent enablement identifier value received by the dependent STA from the enabling STA in the MLME-ENABLEMENT.response primitive.
- The dependent STA shall send a Public Action DSE Registered Location Announcement frame to the broadcast address whenever the sum of dot11TransmittedFragmentCount, dot11GroupTransmittedFrameCount, and dot11ReceivedFragmentCount, modulo dot11DSETransmitDivisor equals 0, possibly delayed by the completion of the sending of the frames of the current MSDU or MMPDU or by the completion of the current transmission opportunity (TXOP).
- A dependent STA that has not attained enablement shall not transmit beyond dot11DSEEnablementTimeLimit (in seconds), measured from the time of the first PHY-TXSTART.request primitive, while attempting to attain enablement. Then if it is not enabled, it shall not transmit for dot11DSEEnablementFailHoldTime (in seconds), before it again attempts to attain enablement.
- A dependent STA receiving a DSE Deenablement frame with the RequesterSTAAddress field matching the enabling STA with which it last attempted enablement and the ResponderSTAAddress field matching its MAC address shall change its enablement state with the enabling STA to unenabled and set all fields of its DSE Registered Location Information field (see 9.4.2.50) to 0.
- A dependent STA shall return a DSE measurement report in response to a DSE measurement request if the request is received from the AP with which it is associated or the enabling STA with which it last attempted enablement and the ResponderSTAAddress field matches its MAC address. The result may be the completed measurement or an indication that the STA is unable to complete the measurement request. A STA shall report it is too late to undertake a measurement request if it receives the request after the specified starting time for the measurement. The Measurement Report Mode field of a frame that is sent in response to a DSE Measurement Request frame shall not contain a value of 1 for the Incapable subfield and shall not contain a value of 1 for the Refused subfield of the Measurement Report Mode field of the DSE measurement report.
- A dependent STA receiving an ECS frame from the enabling STA with which it last attempted enablement or an ECS element from the AP with which it is associated shall perform the ECS procedure (see 11.9.3).
- A dependent STA receiving a DSE Power Constraint frame with the RequesterSTAAddress field matching the enabling STA with which it last attempted enablement and the ResponderSTAAddress field matching its MAC address shall constrain its transmit power to be less than or equal to the maximum transmit power level specified for the current channel in the Country element minus the local power constraint specified in the DSE Power Constraint frame.
- An enabled dependent STA shall cease transmission within dot11DSERenewalTime (in seconds) if it has not received either a Beacon frame or a Probe Response frame from its enabling STA with the RegLoc DSE subfield equal to 1 in the DSE Registered Location element. It shall then change its

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

enablement state with the enabling STA to unenabled and set all fields of its DSE Registered Location Information field (see 9.4.2.50) to 0.

11.12 Group addressed management frame protection procedures

When management frame protection is negotiated, the MLME shall provide an encapsulation service for group addressed robust Management frames. All group addressed robust Management frames shall be submitted to this service for encapsulation and transmission.

In an MBSS, for group addressed Action frames of a category specified with Yes in the Group addressed privacy column of Table 9-81, the group addressed frame protection service shall take the following actions:

— The frames shall be encapsulated and protected with the MGTK using the group data cipher negotiated during the AMPE exchange.

For all other group addressed robust Management frames, the group addressed frame protection service shall take the following actions:

— Management frame protection for multicast/broadcast shall be set using the MLME-SETPROTECTION.request primitive with the Protectlist including a Key Type value of IGTK. A non-AP STA shall also set the Protect Type value to Rx. In an IBSS, a STA shall set the ProtectType value to Rx_Tx. An AP shall set the Protect Type value to Tx.

— The IGTK shall be installed using the MLME-SETKEYS.request primitive with the value IGTK for the Key Type parameter of the SetKeyDescriptor.

— The frames shall be encapsulated and protected using BIP (see 12.5.3).

11.13 SA Query procedures

If a STA and its peer negotiate management frame protection, then the STA shall support the SA Query procedure.

To send an SA Query Request or SA Query Response frame to a peer STA, the SME shall issue an MLME-SA-QUERY.request or MLME-SA-QUERY.response primitive respectively. Reception of an SA Query Request or SA Query Response frame is signaled to the SME with an MLME-SA-QUERY.indication or MLME-SA-QUERY.confirm primitive respectively.

A STA that supports the SA Query procedure and receives an SA Query Request frame shall respond with an SA Query Response frame if none of the following are true:

— The STA is not currently associated to the STA that sent the SA Query Request frame and there is no PTKSA established by PASN authentication.

— The SA Query Request frame was sent to a group address.

— The STA has sent a (Re)Association Request frame within dot11AssociationResponseTimeOut but has not received a corresponding (Re)Association Response frame.

— dot11RSNAOperatingChannelValidationActivated is true and the sending STA had indicated OCVC in its association and either

  — OCI element is not present in the request or

  — Operating channel information indicated does not match the current channel information (see 12.2.10).

A STA that responds with an SA Query Response frame to a STA that indicated OCVC shall include an OCI element in the response frame if dot11RSNAOperatingChannelValidationActivated is true.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When a non-AP or non-PCP STA receives the SA Query Response frame from a STA that indicated OCVC, it shall ensure that OCI element is present in the response and the channel information in the OCI element matches current operating channel parameters (see 12.2.10). Otherwise, the receiving STA shall deem the response as invalid and discard it.

If a STA receives a group addressed SA Query Response frame, it shall deem the response as invalid and discard it.

If a non-AP or non-PCP STA initiated an SA Query procedure following a channel switch and does not receive the SA Query Response frame from a STA that indicated OCVC within dot11AssociationSAQueryMaximumTimeout TUs from the beginning of the SA Query procedure, it shall deauthenticate from the BSS.

NOTE 1—A non-AP and non-PCP STA does not respond if it is trying to reassociate with the AP or PCP that sent the SA Query Request frame (since, except in the case of FT to the same AP, it no longer has the PTKSA) or to another AP or PCP (it could maintain the old association and PTKSA until the reassociation is completed). There is no such restriction for an AP or PCP.

If a non-AP and non-PCP STA that has an SA with its AP or PCP for an association that negotiated management frame protection receives an individually addressed unprotected Deauthentication or Disassociation frame with reason code INVALID_CLASS2_FRAME or INVALID_CLASS3_FRAME from the AP or PCP, the non-AP and non-PCP STA may use this as an indication that there might be a mismatch in the association state between itself and the AP or PCP. In such a case, the non-AP and non-PCP STA's SME may initiate the SA Query procedure with the AP or PCP to verify the validity of the SA by issuing one MLME-SA-QUERY.request primitive every dot11AssociationSAQueryRetryTimeout TUs until a matching MLME-SA-QUERY.confirm primitive is received or dot11AssociationSAQueryMaximumTimeout TUs from the beginning of the SA Query procedure has passed. If the AP or PCP responds to the SA Query request with a valid SA Query response, the non-AP STA should continue to use the SA. If no valid SA Query response is received, the non-AP and non-PCP STA's SME may delete the SA (and temporal keys) held for communication with the STA by issuing an MLME-DELETEKEYS.request primitive and the non-AP and non-PCP STA may move into State 1 (or State 2, for a DMG STA) with the AP.

NOTE 2—The mechanism by which the MAC, MLME and SME coordinate the actions needed to effect these operations is outside the scope of this standard.

When an S1G STA in a power save mode wakes up with an interval longer than dot11AssociationSAQueryMaximumTimeout, an existing SA can be destroyed. So, to maintain its valid SA status, the S1G STA shall wake to listen to SA Query Request frame with the interval specified by dot11AssociationSAQueryMaximumTimeout. When dot11RSNAProtectedManagementFramesActivated is true, an S1G AP shall provide the timeout interval (association comeback time, which is set to dot11AssociationSAQueryMaximumTimeout) in an Association Response frame and Reassociation Response frame with a status code 0 to the S1G STA.

A non-AP STA can identify itself securely when (re)associating with the same AP to avoid the need to use the SA Query procedure and association comeback delay when that non-AP STA and the AP share a common PTK-KCK. The non-AP STA includes a Known STA Identification element in its (Re)Association Request frame to do this, and the AP allows the (re)association to proceed without an SA Query procedure if it receives a valid Known STA Identification element.

The MIC for the Known STA Identification element shall be calculated using the most recently used PTK-KCK and the integrity algorithm (see Table 12-11 for the AKM that was negotiated to be used with that key: MIC(PTK-KCK, Timestamp). The Timestamp value is the most recently received Timestamp field the non-AP STA has received from the AP, e.g., from a Beacon frame. The AP may use this to discard Known STA Identification elements that are based on old information to limit the possibility of replay attacks. The AP should allow timestamp values that it has sent during the last 30 s, or the BSS max idle period, if it is advertised

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

and larger, to be recognized as valid, but the AP may accept a larger window to accommodate cases where the non-AP STA might use cached information for an association. The AP shall discard the Known STA Identification element if the same timestamp value is used more than once. The Known STA Identification element is valid if it was not discarded, and the received MIC matches the locally calculated value. Otherwise, the Known STA Identification element is invalid and shall not be used to skip an SA Query procedure.

11.14 HT BSS Operation

An HT STA that is starting or joining a BSS shall support receiving and transmitting at each of the MCS values listed in the Basic HT-MCS Set field of the HT Operation parameter of the MLME-START.request primitive or Basic HT-MCS Set field of the HT Operation parameter of the SelectedBSS parameter of the MLME-JOIN.request primitive.

A STA that transmits a frame that contains both an HT Operation element and a DSSS Parameter Set element shall set the Primary Channel field in the HT Operation element to the same value as the Current Channel field in the DSSS Parameter Set element.

11.15 20/40 MHz BSS operation

11.15.1 Rules for operation in 20/40 MHz BSS

The rules described in 11.15.1 to 11.15.12 are applicable to STAs that are either a STA 5G or a STA 2G4.

A 40-MHz-capable STA (40MC STA) shall support 20/40 BSS coexistence management.

NOTE—A 40MC HT STA that transmits a frame containing an Extended Capabilities element sets the 20/40 BSS Coexistence Management Support field of this element to 1.

An HT STA 2G4 that is an IBSS STA and that transmits a frame containing an HT Operation element or Secondary Channel Offset element shall set the Secondary Channel Offset field of this element to SCN.

11.15.2 Basic 20/40 MHz BSS functionality

An HT AP declares its channel width capability (20 MHz only or 20/40 MHz) in the Supported Channel Width Set subfield of the HT Capabilities element.

An HT AP shall set the STA Channel Width field to 1 in frames in which it has set the Secondary Channel Offset field to SCA or SCB. An HT AP shall set the STA Channel Width field to 0 in frames in which it has set the Secondary Channel Offset field to SCN.

A non-AP HT STA declares its channel width capability (non-40MC HT STA or 40MC HT STA) in the Supported Channel Width Set subfield in the HT Capabilities element.

NOTE 1—A 20/40 MHz BSS might include any mixture of 40MC HT STAs, non-40MC HT STAs, and non-HT STAs. Protection requirements for mixed networks are defined in 10.27.

NOTE 2—A non-AP HT STA can switch between 40MC HT STA and non-40MC HT STA operation by disassociation followed by association.

An HT STA shall not indicate support for 40 MHz unless it supports reception and transmission of 40 MHz PPDUs using all MCSs within the Basic HT-MCS Set field of the HT Operation parameter of the MLME-START.request primitive or Basic HT-MCS Set field of the HT Operation parameter of the SelectedBSS parameter of the MLME-JOIN.request primitive and all MCSs that are mandatory for the attached PHY.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An HT STA shall not transmit a 20 MHz PPDU containing one or more Data frames using the secondary channel of a 20/40 MHz BSSs. The Notify Channel Width frame may be used by a STA to notify another STA that the STA wishes to receive frames in the indicated channel width.

An HT STA that is an IBSS STA adopts the Secondary Channel Offset field in received frames according to the rules in 11.1.5 and shall not transmit either of the following:

— A value in the Secondary Channel Offset field that differs from the most recently adopted value
— An operating class in the Extended Channel Switch Announcement frame or element with a different behavior than the currently adopted PrimaryChannelLowerBehavior or PrimaryChannelUpperBehavior

11.15.3 Channel scanning and selection methods for 20/40 MHz operation

11.15.3.1 General

An HT STA shall set the following to true: dot11OperatingClassesImplemented, dot11OperatingClassesRequired, and dot11ExtendedChannelSwitchActivated.

An AP operating a 20/40 MHz BSS, on detecting an OBSS whose primary channel is the AP's secondary channel, switches to 20 MHz BSS operation and may subsequently move to a different channel or pair of channels. A DFS owner (DO) operating a 20/40 MHz IBSS, on detecting an OBSS whose primary channel is the DO's secondary channel, may choose to move to a different pair of channels.

NOTE—The setting up of a 40 MHz off-channel TDLS direct link is specified in 11.20.6.3.

11.15.3.2 Scanning requirements for a 20/40 MHz BSS

Before an AP or DO starts a 20/40 MHz BSS, it shall perform a minimum of dot11BSSWidthChannelTransitionDelayFactor OBSS scans (see 11.15.5) to search for existing BSSs.

If the AP or DO starts a 20/40 MHz BSS in the 5 GHz band and the BSS occupies the same two channels as any existing 20/40 MHz BSSs, then the AP or DO shall select a primary channel of the new BSS that is identical to the primary channel of the existing 20/40 MHz BSSs and a secondary channel of the new 20/40 MHz BSS that is identical to the secondary channel of the existing 20/40 MHz BSSs, unless the AP discovers that on these two channels are existing 20/40 MHz BSSs with different primary and secondary channels.

If an AP or DO starts a 20/40 MHz BSS in the 5 GHz band, the selected secondary channel should correspond to a channel on which no beacons are detected during the dot11BSSWidthChannelTransition-DelayFactor OBSS scan time performed by the AP or DO, unless there are beacons detected on both the selected primary and secondary channels.

NOTE 1—The 20/40 MHz channel sets and their corresponding behavior limits (i.e., choice of primary and secondary channels) permissible in each operating class are defined in Annex E and Annex D, respectively.

An HT AP or a DO that is also an HT STA should not start a 20 MHz BSS in the 5 GHz band on a channel that is the secondary channel of a 20/40 MHz BSS.

The AP or DO may continue to periodically scan after the BSS has been started. Information obtained during such scans is used as described within this subclause and within 11.15.2.

After starting a 20 MHz BSS, a 40MC HT AP 2G4 shall perform a minimum of dot11BSSWidthChannelTransitionDelayFactor OBSS scans, either by itself or through its associated STAs before making a transition from a 20 MHz BSS to a 20/40 MHz BSS. When the AP performs the scanning and

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the secondary channel for the 20/40 MHz BSS has been selected, then the scan shall be performed over the set of channels that are allowed operating channels within the current operational regulatory domain and whose center frequency falls within the *affected frequency range* given by Equation (11-1). When the AP performs the scanning without an intended secondary channel for the 20/40 MHz BSS or when the AP's associated STA(s) perform the scanning, then the scan shall be performed on all channels in the frequency band.

NOTE 2—A 40MC HT AP can change from operating a 20 MHz BSS to a 20/40 MHz BSS while maintaining associations by making a change to the transmitted Secondary Channel Offset field.

$$\textit{affected frequency range} = [\frac{f_P + f_S}{2} - 25\ \text{MHz}, \frac{f_P + f_S}{2} + 25\ \text{MHz}] \quad (11\text{-}1)$$

where

f_P is the center frequency of channel P

f_S is the center frequency of channel S

A 40MC HT AP 2G4 shall maintain a MAC variable *20/40 Operation Permitted* that can have either the value true or false. The initial value of *20/40 Operation Permitted* shall be false. The value of *20/40 Operation Permitted* is recomputed according to Equation (11-2) whenever a BSS channel width trigger event is detected or whenever a period of time has elapsed with no BSS channel width triggers being detected and no overlap being reported, as defined in 11.15.12.

$$\begin{aligned} \textit{20/40 Operation Permitted} = {} & (P == OP_i \text{ for all values of } i) \text{ AND} \\ & (P == OT_i \text{ for all values of } i) \text{ AND} \\ & (S == OS_i \text{ for all values of } i) \end{aligned} \quad (11\text{-}2)$$

where

P is the operating or intended primary channel of the 20/40 MHz BSS

S is the operating or intended secondary channel of the 20/40 MHz BSS

OP_i is member i of the set of channels that are members of the channel set C and that are the primary operating channel of at least one 20/40 MHz BSS that was detected within the AP's BSA during the previous dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds

OS_i is member i of the set of channels that are members of the channel set C and that are the secondary operating channel of at least one 20/40 MHz BSS that was detected within the AP's BSA during the previous dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds

OT_i is member i of the set that comprises all channels that are members of the channel set C that were listed at least once in the Channel List fields of 20/40 BSS Intolerant Channel Report elements received during the previous dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds and all channels that are members of the channel set C and that are the primary operating channel of at least one 20 MHz BSS that was detected within the AP's BSA during the previous dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds

C is the set of all channels that are allowed operating channels within the current operational regulatory domain and whose center frequency falls within the *affected frequency range* given by Equation (11-1)

If either side of "==" above is the empty set or has a null value, then the expression is defined to have a Boolean value of true.

A 40MC HT AP 2G4 shall not start a 20/40 MHz BSS in the 2.4 GHz band if the MAC variable *20/40 Operation Permitted* is false (see Equation (11-2)).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A 40MC HT AP 2G4 may transmit a frame containing a Secondary Channel Offset field set to a value of SCA or SCB only if *20/40 Operation Permitted* is true.

In addition to information obtained by the 40MC HT AP 2G4 through its own scanning, a 40MC HT AP 2G4 shall use 20/40 BSS Intolerant Channel Report element information from received 20/40 BSS Coexistence Management frames with an Address 1 field that matches the 40MC HT AP 2G4 using either individual or group addressing, but with no qualification of the Address 3 value, when determining if *20/40 Operation Permitted* is true or false. The information from the Channel List fields of received 20/40 BSS Intolerant Channel Report elements is used in generating the *OT* set for Equation (11-2).

After initial establishment of the 20/40 MHz BSS, if the value of *20/40 Operation Permitted* becomes false, the 40MC HT AP 2G4 reverts to 20 MHz BSS operation (see 11.15.12). The 40MC HT AP 2G4 might subsequently move the BSS to a pair of channels where the value of *20/40 Operation Permitted* evaluates to true.

11.15.3.3 Channel management at the AP and in an IBSS

While operating a 20/40 MHz BSS, a DO or an AP may move its BSS, and an AP may switch the BSS to 20 MHz operation either alone or in combination with a channel move. These channel moving or BSS width switching operations might occur if, for example, another BSS starts to operate in either or both of the primary or secondary channels, or if radar is detected in either or both of the primary or secondary channels, or for other reasons that are beyond the scope of this standard. Specifically, the AP or DO may move its BSS to a different pair of channels, and the AP may separately, or in combination with the channel switch, change from a 20/40 MHz BSS to a 20 MHz BSS using either the primary channel of the previous channel pair or any other available 20 MHz channel. While operating a 20 MHz BSS, a DO or an AP may move its BSS, and an AP may switch the BSS to a 20/40 MHz BSS, either alone or in combination with a channel move.

When switching a 20/40 MHz BSS to an operating channel width of 20 MHz, the AP may recalculate the TS bandwidth budget and may delete one or more active TSs by invoking the MLME-DELTS.request primitive with a ReasonCode value of SERVICE_CHANGE_PRECLUDES_TS.

An AP switches between 20/40 MHz BSS and 20 MHz BSS as follows:

— By changing the Secondary Channel Offset field of the HT Operation element in the Beacon frame, and/or
— By changing the Secondary Channel Offset field of the Secondary Channel Offset element, and/or
— Through the New Operating Class field of transmitted Extended Channel Switch Announcement elements.

In order to maintain existing associations and/or minimize disruption to communications with other STAs while making a channel width change or while performing a channel pair relocation, an AP may inform HT STAs within its BSS that it is making the change by including an Extended Channel Switch Announcement element in Beacon, Probe Response, and Extended Channel Switch Announcement frame transmissions until the intended channel switch time. A DO may inform HT STAs within its BSS that it is performing a channel pair relocation by including an Extended Channel Switch Announcement element in Beacon, Probe Response, and Extended Channel Switch Announcement frame transmissions until the intended channel switch time. The New Channel Number field of the Extended Channel Switch Announcement element represents the new channel (when the BSS after relocation/width change is a 20 MHz BSS) or the primary channel of the new pair of channels (when the BSS after relocation/width change is a 20/40 MHz BSS). When changing to a new pair of channels, the New Operating Class field specifies the position of the secondary channel relative to the new primary channel, i.e., either above or below.

When transmitting HT Operation elements, Channel Switch Announcement elements, and/or Extended Channel Switch Announcement elements, the AP moving the BSS or changing its channel width selects a

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

combination of operating parameters from any single row of any one of the tables in Annex E that is appropriate for the current operating domain of the AP. Similarly, when transmitting HT Operation elements, Channel Switch Announcement elements, and/or Extended Channel Switch Announcement elements, the DO moving the BSS selects a combination of operating parameters from any single row of any one of the tables in Annex E that is appropriate for the current operating domain of the DO. The AP or DO selects one channel number from the Channel set column of the selected row. The AP or DO includes the selected information in subsequently transmitted frames that contain any combination of the following four elements:

— HT Operation element
— Channel Switch Announcement element
— Extended Channel Switch Announcement element
— Secondary Channel Offset element

The AP or DO shall set the Secondary Channel Offset field of transmitted HT Operation elements and transmitted Secondary Channel Offset elements to SCA if the Behavior limits set column of the selected row contains the value PrimaryChannelLowerBehavior. The AP or DO shall set the Secondary Channel Offset field of transmitted HT Operation elements and transmitted Secondary Channel Offset elements to SCB if the Behavior limits set column of the selected row contains the value PrimaryChannelUpperBehavior. The AP or DO shall set the Secondary Channel Offset field of transmitted HT Operation elements and transmitted Secondary Channel Offset elements to SCN if the Behavior limits set column of the selected row contains neither the value PrimaryChannelLowerBehavior nor the value PrimaryChannelUpperBehavior.

The AP or DO shall set the New Channel Number field of transmitted Channel Switch Announcement elements and Extended Channel Switch Announcement elements to the value of the selected channel from the selected row.

The AP or DO shall set the New Operating Class field of transmitted Extended Channel Switch Announcement elements to the value of the Operating class column of the selected row.

Movement of a 20/40 MHz BSS from one channel pair to a different channel pair and changing between 20 MHz and 20/40 MHz operation should be scheduled so that all STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Extended Channel Switch Announcement element or Channel Switch Announcement element before the switch.

When the Extended Channel Switch Announcement element and Extended Channel Switch Announcement frame are transmitted in bands where dot11SpectrumManagementRequired is true, the Channel Switch Announcement element and Channel Switch Announcement frame may also be transmitted. A STA that announces a channel switch using both the Extended Channel Switch Announcement element and the Channel Switch Announcement element shall set the New Channel Number field of both elements to the same value. An HT STA that receives a channel switch announcement through both the Extended Channel Switch Announcement element and the Channel Switch Announcement element ignores the received Channel Switch Announcement element; this is called a *superseded* Channel Switch Announcement element.

For 20 MHz operation when the new operating class signifies 40 MHz channel spacing, the 20 MHz channel is the primary channel of the 40 MHz channel.

11.15.4 40 MHz PPDU transmission restrictions

11.15.4.1 Fields used to determine 40 MHz PPDU transmission restrictions

Several fields from various frames are used to convey information between STAs regarding the support for 40 MHz PPDU transmission and reception and regarding any current prohibition against the transmission and reception of 40 MHz PPDUs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The rules defined in 11.15.4.2, 11.15.4.3, and 11.15.4.4 describe the behavior that accompanies those fields.

The fields that are used to determine the status of the transmission and reception of 40 MHz PPDUs are as follows:

— The Supported Channel Width Set subfield of the HT Capabilities element
— The Secondary Channel Offset field of the HT Operation element
— The STA Channel Width field of the HT Operation element
— The Channel Width field of the Notify Channel Width frame
— The Extended Channel Switch Announcement element

The Supported Channel Width Set subfield is used to indicate whether the transmitting STA is capable of transmitting and receiving 40 MHz PPDUs.

NOTE—The Supported Channel Width Set subfield transmitted by an AP is constant for the lifetime of its BSS as it is a parameter of the MLME-START.request primitive.

In addition to the restrictions on transmission of 40 MHz mask PPDUs found in 11.15.4.1 to 11.15.4.4, if a STA operating in the 2.4 GHz industrial, scientific, and medical (ISM) band has no means of determining the presence of non-IEEE-802.11 communication devices operating in the area, then the STA shall not transmit any 40 MHz mask PPDUs.

In addition to the restrictions on transmission of 40 MHz mask PPDUs found in 11.15.4.1 to 11.15.4.4, if a STA operating in the 2.4 GHz ISM band has a means of determining the presence of non-IEEE-802.11 communication devices operating in the area and determines either that no non-IEEE-802.11 communication device is operating in the area or that non-IEEE-802.11 communication devices are operating in the area but the STA implements a coexistence mechanism for these non-IEEE-802.11 communication devices, then the STA may transmit 40 MHz mask PPDUs; otherwise, the STA shall not transmit any 40 MHz mask PPDUs.

11.15.4.2 Infrastructure non-AP STA restrictions

A STA that is associated with an AP shall not transmit a value in the Supported Channel Width Set subfield that differs from a previously transmitted value during its current association.

The Secondary Channel Offset field is used to indicate whether the BSS is occupying a 40 MHz wide pair of channels and, when a secondary channel exists, whether it is above or below the primary channel in frequency. The Extended Channel Switch Announcement frame and the Extended Channel Switch Announcement element can each be used to indicate a transition from 20/40 MHz BSS operation to 20 MHz BSS operation and vice versa and to indicate whether a secondary channel, when it exists, is above or below the primary channel in frequency.

A 40MC HT STA shall maintain a MAC variable *40MHzOperatingClass* as described here. The initial value of *40MHzOperatingClass* shall be false. The value of *40MHzOperatingClass* is recomputed according to the rules in this subclause at every TBTT and following the reception of a frame transmitted by the AP associated with the STA when that frame contains either of the following fields:

— Current Operating Class field
— New Operating Class field

The MAC variable *40MHzOperatingClass* becomes true upon reception of a frame transmitted by the associated AP if the frame contained a Current Operating Class field with a value that corresponds to an operating class that corresponds to a channel spacing value of 40 MHz, as specified in Annex E.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The MAC variable *40MHzOperatingClass* becomes false upon reception of a frame transmitted by the associated AP if the frame contained a Current Operating Class field with a value that corresponds to an operating class that does not correspond to a channel spacing value of 40 MHz.

The MAC variable *40MHzOperatingClass* becomes true at the n^{th} TBTT following reception of a frame transmitted by the associated AP that contains an Extended Channel Switch Announcement element with a value of *n* in the Channel Switch Count field and a value in the New Operating Class field that corresponds to an operating class that corresponds to a channel spacing value of 40 MHz provided that the frame is the most recently received frame meeting the above conditions.

The MAC variable *40MHzOperatingClass* becomes false at the n^{th} TBTT following reception of a frame transmitted by the associated AP that contains an Extended Channel Switch Announcement element with a value of *n* in the Channel Switch Count field and a value in the New Operating Class field that corresponds to an operating class that does not correspond to a channel spacing value of 40 MHz provided that the frame is the most recently received frame meeting the above conditions.

A STA can choose to dynamically constrain its operating channel width to 20 MHz while being a member of a 20/40 MHz BSS. Transitions to and from this constrained state are indicated using the transmission of a frame that carries the Channel Width field. A Channel Width field value of 0 indicates that the transmitting STA is not currently able to receive 40 MHz PPDUs, beginning at the end of the transmission of the frame that contained the Channel Width field.

A STA shall not transmit a frame containing a STA Channel Width field or a Channel Width field set to 1 if the value of its Supported Channel Width Set subfield is 0.

A STA that is associated with an infrastructure BSS (STA1) shall not transmit a 40 MHz PPDU containing one or more frames addressed to another STA (STA2) unless the following three conditions are true:

— The Supported Channel Width Set subfield of the HT Capabilities element of both STAs is equal to 1.
— The Secondary Channel Offset field of the most recently received HT Operation element sent by the AP of the BSS has a value of SCA or SCB.
— The MAC variable *40MHzOperatingClass* is true.

If the above three conditions are met, STA1 should not transmit a 40 MHz PPDU containing one or more frames addressed to STA2 unless the following two conditions are true:

— Either STA1 has not received a Notify Channel Width frame that was transmitted by STA2, or the Channel Width field of the most recently received Notify Channel Width frame at STA1 that was transmitted by STA2 is nonzero.
— If STA2 is an AP, the STA Channel Width field of the most recently received HT Operation element that was transmitted by STA2 is equal to 1.

11.15.4.3 AP restrictions

An AP shall not transmit a 40 MHz PPDU containing one or more frames addressed to another STA unless the following three conditions are true:

— The Supported Channel Width Set subfield of the HT Capabilities element of the AP and all associated STAs are not equal to 0.
— The Secondary Channel Offset field of the AP's most recently transmitted HT Operation element has a value of SCA or SCB.
— The MAC variable *40MHzOperatingClass* is true.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the above three conditions are met, the AP should not transmit a 40 MHz PPDU containing frames addressed to another STA unless either the AP has not received a Notify Channel Width frame that was transmitted by the STA or the Channel Width field of the most recently received Notify Channel Width frame at the AP that was transmitted by the STA is nonzero.

An AP shall not transmit a 40 MHz PPDU containing one or more frames with a group address in the Address 1 field unless the following three conditions are true:

— The Supported Channel Width Set subfield of the HT Capabilities element of the AP is equal to 1.
— The Secondary Channel Offset field of the AP's most recently transmitted HT Operation element has a value of SCA or SCB.
— The MAC variable *40MHzOperatingClass* is true.

If the above three conditions are met, the AP should not transmit a 40 MHz PPDU containing one or more frames with a group address in the Address 1 field unless either the AP has not received a Notify Channel Width frame from any STA in the BSS or the Channel Width field of the most recently received Notify Channel Width frame from each STA that transmitted a Notify Channel Width frame is nonzero.

11.15.4.4 Restrictions on non-AP STAs that are not infrastructure BSS members

An HT STA 2G4 that is not a member of an infrastructure BSS shall not transmit a 40 MHz mask PPDU.

An HT STA 5G that is not associated with an infrastructure BSS (STA1) shall not transmit a 40 MHz PPDU containing frames addressed to another STA (STA2) unless the following three conditions are true:

— The Supported Channel Width Set subfield of the HT Capabilities element of both STAs is equal to 1.
— The Secondary Channel Offset field of the most recently received HT Operation element sent by STA2 has a value of SCA or SCB.
— The Secondary Channel Offset field of the most recently transmitted HT Operation element sent by STA1 has a value of SCA or SCB.

If the above three conditions are met, STA1 should not transmit a 40 MHz PPDU containing one or more frames addressed to STA2 unless STA1 has not received a STA Channel Width field that was transmitted by STA2 or the most recently received STA Channel Width field at STA1 that was transmitted by STA2 is nonzero.

An HT STA 5G that is not associated with an infrastructure BSS (STA1) shall not transmit a 40 MHz PPDU containing one or more frames with a group address in the Address 1 field unless the following two conditions are true:

— The Supported Channel Width Set subfield of the HT Capabilities element transmitted by STA1 is equal to 1.
— The Secondary Channel Offset field of the HT Operation element most recently transmitted by STA1 has a value of SCA or SCB.

If the above two conditions are met, STA1 should not transmit a 40 MHz PPDU containing one or more frames with a group address in the Address 1 field unless the most recently received STA Channel Width field for each other known member of the BSS of which STA1 is a member is equal to 1.

11.15.5 Scanning requirements for 40MC HT STA 2G4

An OBSS scan operation is a passive or active scan of a set of channels that are potentially affected by 20/40 MHz BSS operation, i.e., the 20 MHz channels that wholly or partly overlap the 40 MHz signal. Each channel in the set may be scanned more than once during a single OBSS scan operation. OBSS scans are

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

performed by STAs that are 40MC HT STA 2G4. STAs that are 40MC HT STA 5G are not required to perform OBSS scan operations.

NOTE 1—STAs that perform OBSS scans report discovered BSSs and received 20/40 BSS coexistence information to their associated AP (see 11.15.12).

During an individual scan within an OBSS scan operation, the minimum per-channel scan duration is dot11OBSSScanPassiveDwell TU (when scanning passively) or dot11OBSSScanActiveDwell TU (when scanning actively). During an OBSS scan operation, each channel in the set is scanned at least once per dot11BSSWidthTriggerScanInterval seconds, and the minimum total scan time (i.e., the sum of the scan durations) per channel within a single OBSS scan operation is dot11OBSSScanPassiveTotalPerChannel TU for a passive scan and dot11OBSSScanActiveTotalPerChannel TU for an active scan.

NOTE 2—The values provided in the previous paragraph indicate the minimum requirements. For some combinations of parameter values, it is necessary to exceed the minimum values of some parameters in order to meet the minimum value constraints of all parameters.

When an AP transmits an Overlapping BSS Scan Parameters element, the value of each of the fields of the element shall be set to the MIB attribute from the transmitting AP's MIB according to the mapping between the frame fields and MIB attributes as defined in 9.4.2.57.

Upon receipt of a frame containing an Overlapping BSS Scan Parameters element from the AP with which a 40MC HT STA 2G4 is associated, the MLME of the receiving 40MC HT STA 2G4 shall update each of the values of the MIB attributes used during OBSS scanning operations according to the mapping between the frame fields and MIB attributes as defined in 9.4.2.57.

A 40MC HT AP 2G4 may transmit frames containing an Overlapping BSS Scan Parameters element to any or all associated STAs in order to provide OBSS scan parameter values that are different from the default values.

A 40MC HT STA 2G4 that is associated with a 40MC HT AP 2G4 shall perform at least one OBSS scan every dot11BSSWidthTriggerScanInterval seconds, unless the 40MC HT STA 2G4 satisfies the conditions described in 11.15.6.

11.15.6 Exemption from OBSS scanning

A 40MC HT STA 2G4 shall maintain a MAC variable *ActivityFraction*. The value of *ActivityFraction* is defined by Equation (11-3).

$$ActivityFraction = \frac{T_{ACTIVE}}{T_{MEASURE\text{-}ACTIVE}} \tag{11-3}$$

where

T_{ACTIVE} is the total duration of transmitted MSDUs and received individually addressed MSDUs during the previous $T_{MEASURE\text{-}ACTIVE}$ seconds

$T_{MEASURE\text{-}ACTIVE}$ is dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds

A 40MC HT STA 2G4 may transmit to its associated AP a 20/40 BSS Coexistence Management frame with the Scanning Exemption Request field in the 20/40 BSS Coexistence element set to 1.

If the last 20/40 BSS Coexistence Management frame received by a 40MC HT STA 2G4 in an individually addressed frame from its associated AP has the Scanning Exemption Grant field equal to 1, the STA is

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

exempted from scanning whenever the value of its MAC variable *ActivityFraction* is less than dot11OBSSScanActivityThreshold/10 000.

A 40MC HT AP 2G4 shall not transmit a 20/40 BSS Coexistence Management frame with the Scanning Exemption Grant field set to 1 addressed to a 40MC HT STA if the following condition is true:

— The 40MC HT STA has transmitted one or more channel report elements and is the only STA in the BSS that has indicated one or more channels on which a STA has found conditions that disallow the use of a 20/40 MHz BSS.

If there is more than one 40MC HT STA in the BSS that has indicated conditions that disallow the use of 20/40 MHz BSS on a specific channel, then the following apply:

— If all of the 40MC HT STAs that have indicated unavailability of a channel have also requested to be exempt from scanning, the AP shall disallow at least one of the 40MC HT STA to be exempt from scanning.

— If, from the group of 40MC HT STAs that have indicated unavailability of a channel, there is at least one 40MC HT STA that has not requested to be exempt from scanning, the AP may allow all of the STAs that have requested to be exempt from scanning to be exempted from scanning.

11.15.7 Communicating 20/40 BSS coexistence information

In addition to the 20/40 BSS Coexistence Management frame, a STA can include the 20/40 BSS Coexistence element in transmitted Beacon, Probe Request, Probe Response, (Re)Association Request, and (Re)Association Response frames.

11.15.8 Support of DSSS/CCK in 40 MHz

Transmission and reception of PPDUs using DSSS/CCK by 40MC HT STAs is managed using the DSSS/CCK Mode in 40 MHz subfield of the HT Capability Information field in the HT Capabilities element (see 9.4.2.54.2).

An HT STA declares its capability to use DSSS/CCK rates while it has a 40 MHz operating channel width through the DSSS/CCK Mode in 40 MHz subfield of its (Re)Association Request frames.

If the DSSS/CCK Mode in 40 MHz subfield is equal to 1 in Beacon and Probe Response frames, an associated HT STA in a 20/40 MHz BSS may generate DSSS/CCK transmissions. If the subfield is equal to 0, then the following apply:

— An associated HT STA shall not generate DSSS/CCK transmissions.

— The AP shall not include an ERP element in its Beacon and Probe Response frames.

— The AP shall not include DSSS/CCK rates in the Supported Rates and BSS Membership Selectors element or Extended Supported Rates and BSS Membership Selectors element.

— The AP shall refuse association requests from a STA that includes only DSSS/CCK rates in its Supported Rates and BSS Membership Selectors element and Extended Supported Rates and BSS Membership Selectors element.

— The DSSS/CCK Mode in 40 MHz subfield transmitted by a (re)associating STA is ignored.

A STA not operating in the 2.4 GHz band shall set the DSSS/CCK Mode in 40 MHz subfield to 0.

11.15.9 STA CCA sensing in a 20/40 MHz BSS

This subclause defines CCA sensing rules for an HT STA that is not a VHT STA. For rules related to a VHT STA, see 10.3.2.7, 10.23.2.7, and 10.23.3.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA may transmit a 20 MHz mask PPDU in the primary channel following the rules in 10.23.2.

A STA transmitting a 40 MHz mask PPDU that begins a TXOP using EDCA as described in 10.23.2.4 or that is using a PIFS as permitted in 10.3.2.3.4 shall sense CCA on both the 20 MHz primary channel and the 20 MHz secondary channel before the 40 MHz mask PPDU transmission starts.

Unless explicitly stated otherwise, a STA may treat a PHY-CCA.indication(BUSY) primitive as a PHY-CCA.indication(IDLE) primitive in the following cases:

— If the channel-list parameter is present and equal to {secondary} and the STA is transmitting a 20 MHz mask PPDU on the primary channel, or

— If the channel-list parameter is present and equal to {primary} and the STA is transmitting a 20 MHz mask PPDU on the secondary channel.

NOTE 1—Transmission of PPDUs on the secondary channel is also subject to constraints in 11.15.2.

At the specific slot boundaries (see Figure 10-29) determined by the STA based on the 20 MHz primary channel CCA, when the transmission begins a TXOP using EDCA (as described in 10.23.2.4), the STA may transmit a pending 40 MHz mask PPDU only if the secondary channel has also been idle during the times the primary channel CCA is performed (defined in 10.23.2.4) during an interval of a PIFS for the 5 GHz band and DIFS for the 2.4 GHz band immediately preceding the expiration of the backoff counter. If a STA was unable to transmit a 40 MHz mask PPDU because the secondary channel was occupied during this interval, it may take one of the following steps:

a) Transmit a 20 MHz mask PPDU on the primary channel.

b) Restart the channel access attempt. In this case, the STA shall invoke the backoff procedure as specified in 10.23.2 as though the medium is busy as indicated by either physical or virtual CS and the backoff counter has a value of 0.

NOTE 2—As a result of this rule, the STA selects a new random number using the current value of CW[AC], and the retry counts are not updated.

When a TXOP is obtained for a 40 MHz PPDU, the STA may transmit 40 MHz PPDUs and/or 20 MHz PPDUs during the TXOP. When the TXOP is obtained by the exchange of 20 MHz PPDUs only in the primary channel, the STA shall not transmit 40 MHz PPDUs during the TXOP.

11.15.10 NAV assertion in 20/40 MHz BSS

An HT STA shall update its NAV using the Duration/ID field value in any frame received in a 20 MHz PPDU in the primary channel or received in a 40 MHz PPDU and that does not have an RA matching the STA's MAC address.

NOTE—A STA need not set its NAV in response to 20 MHz frames received on the secondary channel or any other channel that is not the primary channel, even if it is capable of receiving those frames.

11.15.11 Signaling 40 MHz intolerance

An HT STA 2G4 shall set the Forty MHz Intolerant field to 1 in transmitted HT Capabilities elements if dot11FortyMHzIntolerant is true; otherwise, the field shall be set to 0.

A STA 2G4 shall set the Forty MHz Intolerant field to 1 in transmitted 20/40 BSS Coexistence fields if dot11FortyMHzIntolerant is true; otherwise, the field shall be set to 0. A STA 2G4 that is not an HT STA 2G4 shall include a 20/40 BSS Coexistence element in Management frames in which the element may be present if dot11FortyMHzIntolerant is present and dot11FortyMHzIntolerant is true.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA 5G shall set the Forty MHz Intolerant field to 0 in transmitted HT Capabilities elements and 20/40 BSS Coexistence fields.

11.15.12 Switching between 40 MHz and 20 MHz

A VHT STA is not required to perform any of the behavior described in this subclause associated with Information Request and 20 MHz BSS Width Request.

The following events are defined to be BSS channel width trigger events (TEs):

— **TE-A**: On any of the channels of the channel set defined in Clause 18, reception of a Beacon frame that does not contain an HT Capabilities element.

— **TE-B**: On any of the channels of the channel set defined in Clause 18, reception of a 20/40 BSS Coexistence Management, Beacon, Probe Request, or Probe Response frame that contains a value of 1 in a Forty MHz Intolerant field and that has the Address 1 field equal to the receiving STA's address or to a group address, with no further addressing qualifications.

— **TE-C**: Reception of a 20/40 BSS Coexistence Management frame with the 20 MHz BSS Width Request field equal to 1 and with an Address 1 field that matches the receiving STA using either individual or group addressing and with a TA field that corresponds to the MAC address of a STA with which the receiver is associated.

— **TE-D**: Reception of a 20/40 BSS Coexistence Management frame containing at least one 20/40 BSS Intolerant Channel Report element with a nonzero length and with an Address 1 field equal to the receiving STA's address or to a group address, but with no qualification of the Address 3 field.

A 40MC HT AP 2G4 shall reevaluate the value of the MAC variable *20/40 Operation Permitted* (see 11.15.3.2) when either of the following events occurs:

— A BSS channel width trigger event TE-A is detected.

— A BSS channel width trigger event TE-D is detected.

A 40MC HT AP 2G4 may reevaluate the value of the MAC variable *20/40 Operation Permitted* (see 11.15.3.2) when either of the following situations occurs:

— No BSS channel width trigger events TE-A are detected for a period of time equal to dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds.

— No BSS channel width trigger events TE-D are detected for a period of time equal to dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds.

A 40MC HT AP 2G4 that detects either BSS channel width trigger event TE-B or TE-C or that determines that the value of the MAC variable *20/40 Operation Permitted* has changed from true to false shall set the Secondary Channel Offset field to SCN in transmitted HT Operation elements beginning at the next DTIM beacon or next TBTT if no DTIM beacons are transmitted to indicate that no secondary channel is present (i.e., that the BSS operating width is 20 MHz).

A 40MC HT AP 2G4 shall not set the Secondary Channel Offset field to a value of SCA or SCB in transmitted HT Operation elements unless the following two conditions have been met:

— A period of dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds have elapsed during which no BSS channel width trigger events TE-B or TE-C are detected.

— The value of the MAC variable *20/40 Operation Permitted* (see 11.15.3.2) is true.

To request an update of the status of the 20 MHz BSS Width Request field, a 40MC HT AP 2G4 can transmit a 20/40 BSS Coexistence Management frame with a value of 1 in the Information Request field as described in 11.16.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A 40MC HT STA 2G4 that is associated with a 40MC HT AP 2G4 shall maintain a record of detected BSS channel width trigger events as follows:

- For each detected BSS channel width trigger event TE-A:
  - If a DSSS Parameter Set field is present in the received Beacon frame, the channel of the BSS channel width trigger event is set to the value of the Current Channel field of the DSSS Parameter Set field; otherwise, the channel of the BSS channel width trigger event is the channel on which the detecting STA received the Beacon frame.
  - If a Supported Operating Classes element is present in the received Beacon frame, the operating class of the BSS channel width trigger event is the value of the Current Operating Class field of the Supported Operating Classes element of the received Beacon frame; otherwise, the operating class of the BSS channel width trigger event is "unknown."
- For each detected BSS channel width trigger event TE-A of a unique combination of operating class and channel, the 40MC HT STA 2G4 shall maintain a record containing two MAC variables:
  - The operating class of the BSS channel width trigger event
  - The channel of the BSS channel width trigger event

NOTE—If a BSS channel width trigger event TE-A is detected for an operating class and channel combination for which no record exists, the STA creates such a record.

If a BSS channel width trigger event TE-A is detected for an operating class and channel combination for which a record already exists, the information in that record shall be updated with the information determined from the new trigger event.

For all BSS channel width trigger events TE-B, the 40MC HT STA 2G4 shall maintain a single record containing an indication of whether one or more trigger events TE-B have been detected.

At the completion of an OBSS scan operation (i.e., at the end of the period of time equal to dot11BSSWidthTriggerScanInterval) or when it receives a 20/40 BSS Coexistence Management frame from its associated AP that contains a value of 1 in the Information Request field, a 40MC HT STA 2G4 that is associated with a 40MC HT AP 2G4 shall create a 20/40 BSS Coexistence Management frame by including a value of 0 for all fields of a 20/40 BSS Coexistence Management frame and then transferring information from the BSS channel width trigger event TE-A and TE-B records to the frame according to the following four steps:

- For each unique operating class that is stored in the set of BSS channel width trigger event TE-A records, the STA shall create a 20/40 BSS Intolerant Channel Report element for inclusion in the frame and include all of the unique channels associated with the operating class in the channel list of that element.
- The STA sets the Forty MHz Intolerant field of the 20/40 BSS Coexistence element per the rules listed in 11.15.11.
- The STA shall set to 1 the 20 MHz BSS Width Request field of the 20/40 BSS Coexistence element for inclusion in the frame if a record for BSS channel width trigger event TE-B exists and indicates that at least one trigger event TE-B has been detected.
- The STA may set to 1 the Information Request field.

Upon completion of these four steps, the 40MC HT STA 2G4 shall delete all records for trigger events TE-A and TE-B. Subsequently detected trigger events cause the creation of new records as necessary to be used in subsequently generated 20/40 BSS Coexistence Management frames. Following the record deletion, the 40MC HT STA 2G4 shall transmit to its associated 40MC HT AP 2G4 the 20/40 BSS Coexistence Management frame if any of the following conditions is true:

- At least one 20/40 BSS Intolerant Channel Report element with the Length field not equal to 0 is included.
- The Forty MHz Intolerant field is equal to 1.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The 20 MHz BSS Width Request field is equal to 1.
— The Information Request field is equal to 1.
— The frame was created in response to an Information Request field that was equal to 1.

11.16 20/40 BSS Coexistence Management frame usage

A STA that supports the 20/40 BSS Coexistence Management frame type shall set the 20/40 BSS Coexistence Management Support field to 1 in transmitted Extended Capabilities elements.

A STA that supports the 20/40 BSS Coexistence Management frame type shall include an Extended Capabilities element in transmitted Beacon, (Re)Association Request, (Re)Association Response, Probe Request, and Probe Response frames.

A STA shall not transmit to another STA a 20/40 BSS Coexistence Management frame with an individual address in the Address 1 field if the Extended Capabilities element from the recipient STA contained a value of 0 in the 20/40 BSS Coexistence Management Support field. A STA that transmits a 20/40 BSS Coexistence Management frame may set the Address 1 field to a group address.

NOTE—A 20/40 BSS Coexistence Management frame is a Class 1 frame and, therefore, can be sent to a STA that supports reception of such frames and that is not a member of the same BSS as the transmitting STA. In such a case, the BSSID field of the frame is set to the wildcard BSSID, regardless of whether the Address 1 field contains an individual or group address value.

A STA may transmit a 20/40 BSS Coexistence Management frame that contains a value of 1 for the Request Information field to another STA that supports the transmission of and reception of the 20/40 BSS Coexistence Management frame, except when the frame is a response to a 20/40 BSS Coexistence Management frame that contains a value of 1 for the Request Information field.

A non-VHT STA that receives a 20/40 BSS Coexistence element with the Information Request field equal to 1, an Address 1 field that matches the receiving STA using an individual address, and a nonwildcard BSSID field that matches the STA's BSS shall immediately queue for transmission a 20/40 BSS Coexistence Management frame with the transmitting STA as the recipient.

11.17 Public Action frame addressing

A STA that is a member of a BSS and that transmits an individually addressed Public Action frame to a STA that is not a member of the same BSS shall set the BSSID field of the frame as follows:

— If the recipient STA is known to be a member of another BSS (including being an AP) and that BSS's BSSID is known, the BSSID field shall be set to the BSS's BSSID or the wildcard BSSID.
— Otherwise, the BSSID field of the frame shall be set to the wildcard BSSID.

A STA that is a member of a BSS and that transmits a group addressed Public Action frame shall set the BSSID field of the frame to the BSS's BSSID or the wildcard BSSID.

A STA that is a member of a BSS and that transmits an individually addressed Public Action frame to a STA that is a member of the same BSS shall set the BSSID field of the frame to the BSS's BSSID.

A STA that is not a member of a BSS and that transmits a Public Action frame shall set the BSSID field of the frame as follows:

— If the frame is individually addressed, the recipient STA is known to be a member of a BSS (including being an AP), and that BSS's BSSID is known, the BSSID field shall be set to the BSS's BSSID or the wildcard BSSID.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— Otherwise, the BSSID field of the frame shall be set to the wildcard BSSID.

If a STA is transmitting an EBCS UL frame, the Address 3 field is set to the EBCS content MAC address (see 34.4 and 34.2). If a STA is transmitting an EBCS Info frame, the Address 3 field is set to the EBCS info MAC address (see 34.3 and 34.2).

11.18 STAs communicating Data frames outside the context of a BSS

When dot11OCBActivated is true in a STA:

a) Synchronization, authentication, association, and frame classes as defined in 11.1 and 11.3 are not used. Data confidentiality as defined in Clause 12 is not used. The STA may send Action frames and, if the STA maintains a TSF Timer, Timing Advertisement frames.

b) The STA may send Control frames, except those of subtype PS-Poll and CF-End. If the STA is a DMG STA for which dot11DMGOCBActivated is true, in addition to not sending Control frames of subtype PS-Poll and CF-End, the STA shall not send Control frames of subtype Poll, SPR, Grant, Grant Ack, Sector Ack, Block Ack Schedule, and TDD Beamforming.

c) The STA may send Data frames of subtype Data, Null, QoS Data, and QoS Null.

d) The STA shall set the BSSID field in all Management and Data frames to the wildcard BSSID.

e) If the STA is a DMG STA for which dot11DMGOCBActivated is true, the STA may send DMG Beacon frames. A STA sending DMG Beacon frames shall set the Discovery Mode field to 1, and set the CBAP Only and CBAP Source subfields in the DMG Parameters field to 1 and 0, respectively.

A STA with dot11OCBActivated equal to true shall not join or start a BSS.

Whenever MAC sublayer and PHY parameters are changed in a STA in which dot11OCBActivated is true, MAC sublayer and PHY operation shall resume with the appropriate MIB attributes in less than 2 TU.

11.19 Timing advertisement

11.19.1 Introduction

A STA may advertise a time standard by transmitting a Timing Advertisement element in one of the following frames: Timing Advertisement, Probe Response, Beacon, DMG Beacon or Announce. As defined in 9.4.2.59 the Time Advertisement element contains two estimates. The Time Value field contains an estimate of the difference between a time standard and the timestamp included in the same frame. The SME shall use the MLME-GETTSFTIME.request primitive to obtain the current value of the TSF timer. The Time Error field contains an estimate of the standard deviation of the error in the estimate in the Time Value field. The time standard might be derived from an external time source. A STA with an external time source might implement an estimator in a variety of ways, which are beyond the scope of this standard.

11.19.2 Timing advertisement frame procedures

The SME provides the Time Advertisement element to the MLME when it requests the MLME to send a Timing Advertisement frame. When a Timing Advertisement frame is received by a STA, its MLME reports the Timestamp, Local Time, Time Advertisement element, and estimates of propagation delay to the SME. For a STA that maintains a TSF Timer and receives a Timing Advertisement frame, Local Time is the value of the STA's TSF timer at the start of reception of the first octet of the Timestamp field of the frame. Otherwise, the Local Time is unspecified. The receiving STA's SME might use the Timestamp, Local Time, and Time Advertisement element to align its estimate of the time standard to the transmitting STA's estimate of the corresponding time standard.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.19.3 UTC TSF Offset procedures

When dot11UTCTSFOffsetActivated is true, the Time Advertisement and Time Zone elements shall be included in all Probe Response frames, the Time Advertisement element shall be included in the Beacon frame every dot11TimeAdvertisementDTIMInterval DTIM intervals, and the Time Advertisement element shall be included in the DMG Beacon frame or in the Announce frame at least every dot11DMGTimeAdvertisementBeaconInterval. When dot11UTCTSFOffsetActivated is false, the Time Advertisement and Time Zone elements shall not be included in Beacon, Probe Response, and Announce frames.

The AP should periodically synchronize to a UTC reference clock (ITU-R Recommendation TF.460-6 (2002) [B61]) so that the UTC TSF offset can account for drift. The AP shall increment the Time Update Counter field value in the Time Advertisement element each time the synchronization occurs. The method the AP uses to synchronize with a UTC reference clock is out of scope of the standard.

11.20 Tunneled direct link setup

11.20.1 General

Tunneled direct link setup (TDLS) is characterized by encapsulating setup frames in Data frames, which allows them to be transmitted through an AP transparently. Therefore, the AP does not need to be direct link capable, nor does it have to support the same set of capabilities that are used on the TDLS direct link between the two TDLS peer STAs. TDLS also includes power saving, in the form of TDLS peer PSM (scheduled) and TPU (unscheduled). STAs that set up a TDLS direct link remain associated with their BSS, but have the option of transmitting frames directly to the other TDLS peer STA.

Transmitting a TDLS frame through the AP means that the frame's RA is set to the BSSID. Transmitting a frame (whether a TDLS frame or another frame) over the direct path means that the frame's RA is set to the MAC address of the TDLS peer STA. An A-MSDU transmitted over the direct path shall not contain an A-MSDU subframe header with a DA field that is a group address.

NOTE 1—This implies that the RA of frames transmitted over the direct path cannot be a group address.

To set up and maintain a TDLS direct link, both TDLS peer STAs shall be associated with the same infrastructure BSS.

A DMG STA shall not use the TDLS protocol.

A TDLS peer STA may be involved in direct links with multiple TDLS peer STAs at the same time.

The primary channel on which the AP operates is referred to as the base channel and a TDLS STA that operates on this channel is referred to as on the base channel. If the direct link is switched to a channel that is not the base channel, then this channel is referred to as the off-channel, and a TDLS STA that operates on this channel is referred to as off-channel.

Features that are supported by both TDLS peer STAs may be used on a TDLS direct link between those STAs regardless of whether they are supported by the BSS. An example is the use of an HT-MCS on a TDLS direct link between HT STAs when these STAs are associated with a non-HT BSS. Features that are supported by the BSS shall follow the BSS rules when they are used on a TDLS direct link on the base channel. The channel width of a TDLS direct link on the base channel shall not exceed the channel width of the BSS of which the TDLS peer STAs are members, except when the TDLS Wider Bandwidth subfield in the Extended Capabilities element of the TDLS Setup Request frame or the TDLS Setup Response frame is 1 for both TDLS peer STAs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A VHT STA with a TDLS direct link that is not an off-channel TDLS direct link shall use as its primary channel the primary channel or the only channel of its BSS. The channel width of a VHT TDLS direct link shall not be wider than the maximum channel width supported by either the TDLS initiator STA or the TDLS responder STA.

A 160 MHz bandwidth is defined to be identical to an 80+80 MHz bandwidth (i.e., one bandwidth is not wider than the other).

A STA shall not participate in a TDLS direct link with the same primary 80 MHz channel as the infrastructure BSS or another TDLS direct link of the STA but with a different secondary 80 MHz channel.

When admission control is required for an AC on the base channel, in order to use this AC for direct link transmissions on the base channel, the TDLS peer STA is responsible for setting up a TS with Direction of Direct Link with the AP, as defined in 10.23.4.2.

An S1G STA with a TDLS direct link that is not an off-channel TDLS direct link shall use as its primary channel the channel indicated by the Primary Channel Number field in the S1G Operation element. The channel width of an S1G TDLS direct link shall not be wider than the maximum channel width supported by either the TDLS initiator STA or the TDLS responder STA.

A non-AP STA may act as TDLS initiator STA or TDLS responder STA when dot11TunneledDirectLinkSetupImplemented is true.

TDLS payloads (which are transmitted in one or more TDLS frames) shall use the formatting as specified in 11.20.2 when they are transmitted through the AP and when they are transmitted over the TDLS direct link. A STA shall not transmit a TDLS Action field in a frame with the Type field of the frame set to Management.

NOTE 2—The TDLS Discovery Response frame is not a TDLS payload (in one or more TDLS frames) but a Public Action frame.

TDLS shall not be used in an IBSS.

TDLS shall not be used in an MBSS.

Security is available on the TDLS direct link only when both TDLS peer STAs have an RSNA with the BSS.

TDLS shall not be used when the TDLS Prohibited subfield included in the Extended Capabilities element of the Association Response frame or Reassociation Response frame that led to the current association is equal to 1.

The HT Operation element shall be present in a TDLS Setup Confirm frame when both STAs are HT capable.

The VHT Operation element shall be present in a TDLS Setup Confirm frame when both STAs are VHT capable and the TDLS direct link is not established in the 2.4 GHz band. When the TDLS Setup Confirm frame includes a VHT Operation element, the Basic VHT-MCS And NSS Set field is reserved.

The HE Operation element shall be present in a TDLS Setup Confirm frame when both STAs are HE capable.

The S1G Operation element shall be present in a TDLS Setup Confirm frame for S1G STA.

Figure 11-37 depicts the TDLS direct-link establishment process. The figure is an example of only the basic procedure and is not meant to be exhaustive of all possible uses of the protocol.

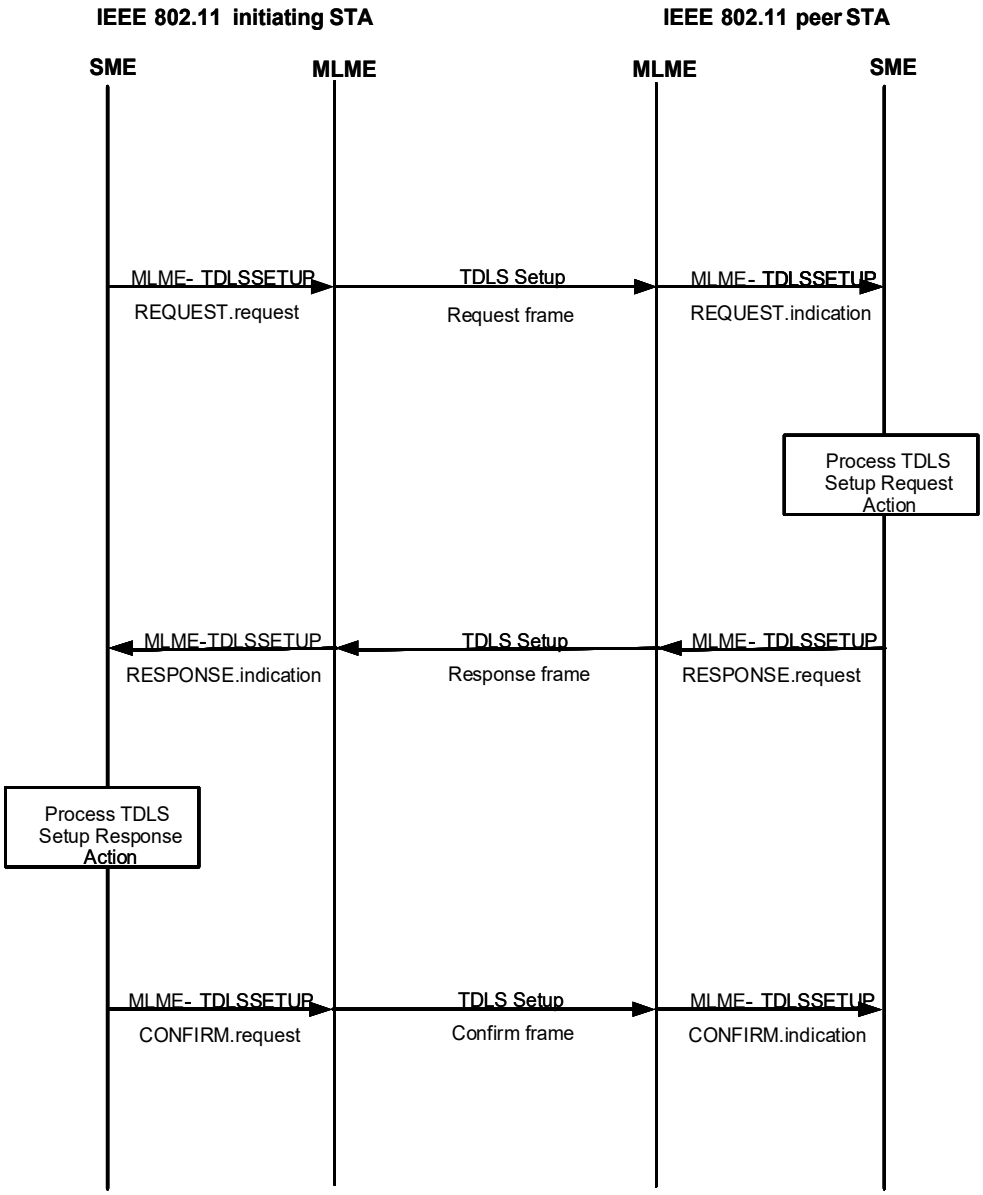

Figure 11-37—TDLS direct link establishment

11.20.2 TDLS payload

TDLS uses MSDUs with EtherType 89-0d, as defined in Annex H, for TDLS signaling. The Payload field of the MSDUs contains one of the TDLS Action fields specified in 9.6.12 followed by zero or more Vendor Specific elements.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.20.3 TDLS discovery

To discover TDLS STAs in the same BSS, a TDLS initiator STA may send a TDLS Discovery Request frame to an individual DA, through the AP. The TDLS responder STA Address field contained in the Link Identifier element of the TDLS Discovery Request frame shall be set to the DA of the TDLS Discovery Request frame. A TDLS STA that receives a TDLS Discovery Request frame with a matching BSSID in the Link Identifier element shall send a TDLS Discovery Response frame to the requesting STA, via the direct path. The

TDLS responder STA Address field contained in the Link Identifier element of the TDLS Discovery Response frame shall be set to the MAC address of the STA sending the TDLS Discovery Response frame.

A TDLS STA may send an individually addressed TDLS Discovery Response frame via the direct path without prior reception of a TDLS Discovery Request frame. A TDLS STA that receives such an unsolicited TDLS Discovery Response frame may respond with an individually addressed TDLS Discovery Response frame. The Dialog Token field of the unsolicited TDLS Discovery Response frame may set to any value. The Link Identifier field shall be populated as specified for the TDLS Discovery Request frame.

NOTE—The first STA might then proceed with TDLS direct link establishment on reception of the TDLS Discovery Response frame from the second STA.

A TDLS Discovery Request frame shall not be sent to a group address. A TDLS Discovery Response frame shall not be sent to a group address.

A TDLS STA may also send a TDLS Setup Request frame to a STA in the same BSS to discover whether the peer STA is a TDLS STA. A TDLS Setup Response frame transmitted in response to a TDLS Setup Request frame indicates that the peer STA sending the TDLS Setup Response frame is a TDLS STA.

A TDLS Discovery Response frame that is a response to a TDLS Discovery Request frame or to an unsolicited TDLS Discovery Response frame is transmitted (i.e., not via the AP) to the TDLS peer STA that sent the corresponding TDLS Discovery Request frame or unsolicited TDLS Discovery Response frame.

An alternative mechanism to discover TDLS STAs in the same BSS, is provided by the TDLS Capability ANQP-element, as described in 11.22.3.3.10. This mechanism allows the ANQP request/response frames to use the direct path between the peer STAs.

11.20.4 TDLS direct link establishment

To establish a TDLS direct link, the TDLS initiator STA shall send a TDLS Setup Request frame to the intended TDLS responder STA.

TDLS Setup Request frames, TDLS Setup Response frames, and TDLS Setup Confirm frames shall be transmitted through the AP and shall not be transmitted to a group address.

Upon receipt of a TDLS Setup Request frame, the following options exist at the TDLS responder STA:

a) The TDLS responder STA accepts the TDLS Setup Request frame, in which case the TDLS responder STA shall respond with a TDLS Setup Response frame with status code SUCCESS.
b) The TDLS responder STA declines the TDLS Setup Request frame, in which case the TDLS responder STA shall respond with a TDLS Setup Response frame with status code REQUEST_DECLINED. A TDLS setup request shall be declined when the BSSID in the received Link Identifier does not match the BSSID of the BSS of which the TDLS responder STA is a member.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

c) The TDLS Setup Request frame is received after sending a TDLS Setup Request frame and before receiving the corresponding TDLS Setup Response frame, and the source address of the received TDLS Setup Request frame is higher than its own MAC address, in which case the TDLS responder STA shall discard the frame and the TDLS responder STA shall send no TDLS Setup Response frame.

d) The TDLS Setup Request frame is received after sending a TDLS Setup Request frame and before receiving the corresponding TDLS Setup Response frame, and the source address of the received TDLS Setup Request frame is lower than its own MAC address. In this case, the TDLS responder STA shall terminate the TDLS setup it initiated. The TDLS responder STA shall send a response according to item a) or item b) above in this case.

e) If a TDLS Setup Request frame is received from a TDLS responder STA with which a currently active TDLS session exists, then the receiving STA shall tear down the existing TDLS direct link as if a TDLS Teardown frame was received, and respond with a TDLS Setup Response frame.

If no TDLS Setup Response frame is received within dot11TDLSResponseTimeout, or if a TDLS Setup Response frame is received with a status code not equal to SUCCESS, the TDLS initiator STA shall terminate the setup procedure and discard the TDLS Setup Response frame. Otherwise, the TDLS initiator STA shall send a TDLS Setup Confirm frame to the TDLS responder STA to confirm the receipt of the TDLS Setup Response frame.

When the BSS does not support EDCA, EDCA may be used on the TDLS direct link (on the base channel and on the off-channel), with the default EDCA Parameter Set, per 10.2.3.2.

If security is required on the TDLS direct link (see 12.7.8.1), then the TPK handshake messages are included in the TDLS Setup frames, as follows:

— TPK handshake message 1 shall be included in the TDLS Setup Request frame.
— TPK handshake message 2 shall be included in the TDLS Setup Response frame.
— TPK handshake message 3 shall be included in the TDLS Setup Confirm frame.

When the TDLS setup handshake has been completed, the TDLS initiator STA and the TDLS responder STA are TDLS peer STAs. A TDLS peer STA shall accept Data frames received from the respective TDLS peer STA directly and Data frames destined for the respective TDLS peer STA may be transmitted over the TDLS direct link.

Subsequent to the successful completion of the TPK handshake, all Data frames transmitted on the TDLS direct link, and all Management frames if management frame protection was negotiated, shall be protected using the TPKSA, per the procedures defined in Clause 12.

To avoid possible reordering of MSDUs, a TDLS initiator STA shall cease transmitting MSDUs to the TDLS responder STA through the AP after sending a TDLS Setup Request frame, and a TDLS responder STA shall cease transmitting MSDUs to the TDLS initiator STA through the AP after sending a TDLS Setup Response frame indicating status code SUCCESS.

The TDLS Setup Request frame and the TDLS Setup Response frame shall be transmitted using the lowest AC that was used for transmitting MSDUs to the respective TDLS peer STA during the previous dot11TDLSACDeterminationInterval seconds, or at AC_BK. When no MSDUs were transmitted during the previous dot11TDLSACDeterminationInterval seconds, then the TDLS Setup Request frame and the TDLS Setup Response frame may be sent at any AC, subject to applicable Admission Control rules.

If no TDLS Setup Response frame is received within dot11TDLSResponseTimeout, or if a TDLS Setup Response frame is received with status code other than SUCCESS, the TDLS initiator STA may resume transmitting MSDUs to the TDLS responder STA through the AP.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If a TDLS Setup Confirm frame is transmitted with a status code other than SUCCESS, the TDLS initiator STA may resume transmitting MSDUs to the TDLS responder STA through the AP.

If a TDLS Setup Confirm frame is received with a status code other than SUCCESS, the TDLS responder STA may resume transmitting MSDUs to the TDLS initiator STA through the AP.

A TDLS peer STA shall not transmit MSDUs over the direct link before transmitting or receiving a TDLS Setup Confirm frame with status code SUCCESS.

11.20.5 TDLS direct link teardown

To tear down a TDLS direct link, a TDLS peer STA shall send a TDLS Teardown frame to the respective TDLS peer STA. A TDLS peer STA shall disable the TDLS direct link and delete the related security parameters after successfully transmitting TDLS Teardown frame. If security is required on the TDLS direct link (see 12.7.8.1), then the FTE shall be included in the TDLS Teardown frame.

The TDLS Teardown frame shall be sent over the direct path and the reason code shall be set to TDLS_TEARDOWN_UNSPECIFIED_REASON except when the TDLS peer STA is unreachable via the TDLS direct link, in which case the TDLS Teardown frame shall be sent through the AP and the reason code shall be set to TDLS_TEARDOWN_PEER_UNREACHABLE. If the TDLS direct link is on an off-channel when this condition occurs, then the TDLS peer STA may switch back to the base channel without initiating a channel switch frame exchange, before transmitting the TDLS Teardown frame.

If present, the contents of the FTE in the TDLS Teardown frame shall be the same as that included in the TPK handshake message 3 with the exception of the MIC field. The MIC shall be calculated on the concatenation, in the following order, of:

— Link Identifier element
— Reason Code
— Dialog token that was used in the MIC calculation for TPK handshake message 3
— Transaction Sequence number (1 octet) which shall be set to the value 4
— FTE, with the MIC field of the FTE set to 0

The MIC shall be calculated using the TPK-KCK and the AES-128-CMAC algorithm. The output of the AES-128-CMAC shall be 128 bits.

If the TPK handshake was successful for this TDLS session, then a receiving STA shall validate the MIC in the TDLS Teardown frame prior to processing the TDLS Teardown frame; a TDLS Teardown frame in which the MIC validation fails is called an *invalid* TDLS Teardown frame. A TDLS peer STA that receives a TDLS Teardown frame that is not an invalid TDLS Teardown frame shall disable the TDLS direct link and delete the related security parameters.

When a TDLS direct link gets torn down, any related TSs shall be deleted by the TDLS peer STAs.

A TDLS Teardown frame with Reason Code LEAVING_NETWORK_DEAUTH shall be transmitted to all TDLS peer STAs (via the AP or via the direct path) prior to reassociation with a different AP, deauthentication, disassociation, or association. After receiving a Deauthentication frame or a Disassociation frame from the AP, a Deauthentication frame with Reason Code LEAVING_NETWORK_DEAUTH shall be transmitted via the direct path to all TDLS peer STAs that are in the awake state, if management frame protection has not been negotiated on the TDLS direct link.

11.20.6 TDLS channel switching

11.20.6.1 General

A STA that supports TDLS channel switching has dot11TDLSChannelSwitchingActivated equal to true and shall set dot11MultiDomainCapabilityActivated and dot11ExtendedChannelSwitchActivated to true. When TDLS channel switching is enabled, the STA may set TDLS Channel Switching subfield to 1. The STA shall include a Supported Channels element and a Supported Operating Classes element in all TDLS Setup Request and TDLS Setup Response frames that have a TDLS Channel Switching subfield equal to 1. The Supported Channels element shall indicate the channels supported for the current operating class. The STA shall include only channels in the Supported Channels element for which it can adhere to the local power constraint. A channel switch shall not be initiated by a STA when the TDLS peer STA did not set the TDLS Channel Switching capability field to 1 in the transmitted TDLS Setup Request frame or the TDLS Setup Response frame that caused the TDLS direct link to be set up.

TDLS Channel Switch Request frames and TDLS Channel Switch Response frames shall be transmitted over the TDLS direct link.

TDLS channel switching is different from (I)BSS channel switching as defined in 11.8.8.

The target channel is the destination channel of an intended channel switch. The target channel is specified by the STA that initiates a channel switch, from the set of operating classes supported by both TDLS peer STAs. The target channel and operating class are specified in the TDLS Channel Switch Request frame. The Country and Coverage Class settings on the target channel are the same as in the BSS of which both TDLS peer STAs are currently members. Both STAs are entitled to request a channel switch. The events occurring for a channel switch are illustrated in Figure 11-38 .

In Figure 11-38 , the TDLS peer STAs (STA1 and STA2) are operating on an initial channel. After contending for the medium, STA1 transmits a TDLS Channel Switch Request frame to STA2, via the TDLS direct link, indicating a requested switch to a target channel. STA2 transmits an Ack frame (denoted ACK1 in Figure 11-38) after a SIFS, and processes the TDLS Channel Switch Request frame. After contending for the medium, STA2 transmits a TDLS Channel Switch Response frame to STA1, possibly also after entering power save mode with the AP. STA1 responds with an Ack frame (denoted ACK2 in Figure 11-38) after a SIFS. If the TDLS Channel Switch Response frame indicated with status code REQUEST_DECLINED, then both STAs continue to operate on the current channel. If the TDLS Channel Switch Response frame indicated with status code SUCCESS, then both STAs shall be listening on the target channel not later than SwitchTime after the end of the PPDU[+SigExt] containing ACK2, as measured on the WM. After switching channels, each TDLS peer STA shall perform a clear channel assessment (CCA) on the target channel, until a frame is detected by which it can set its NAV, or until a period of time equal to dot11TDLSNavSync has transpired (this combined event is indicated as “ProbeTime” in Figure 11-38). The first transmission on the target channel shall be preceded by a random backoff, which shall start at the end of the ProbeTime. The first transmission on the new channel shall not start before the end of SwitchTime. The initiator of the channel switch shall transmit a Data frame on the target channel, unless the SwitchTimeout has expired or the responder to the channel switch transmitted a Data frame on the target channel.

If no successful frame exchange sequence has occurred on an off-channel within SwitchTimeout after the end of the PPDU[+SigExt] containing ACK2, as measured on the WM, a STA shall go back to the base channel, where they shall be listening not later than SwitchTime after the end of the SwitchTimeout. After changing channels (either from the base channel to the off-channel or from the off-channel to the base channel), a TDLS peer STA shall perform CCA until a frame is detected by which it can set its NAV, or until a period of time equal to the ProbeTime has transpired.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

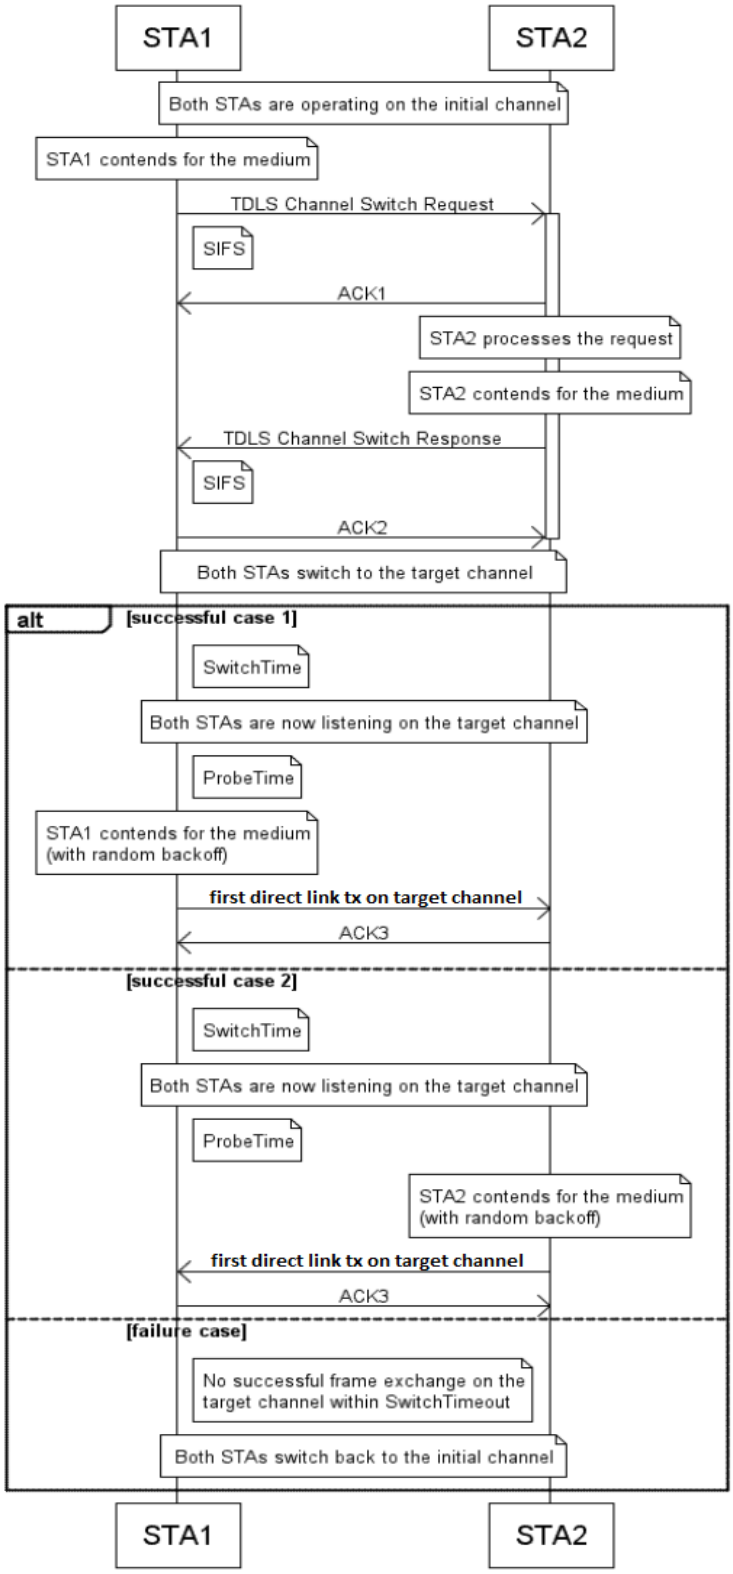

Figure 11-38—Events occurring for a TDLS direct link channel switch

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Both the TDLS Channel Switch Request frame and the TDLS Channel Switch Response frame shall contain a Channel Switch Timing element. The SwitchTime and SwitchTimeout values in the TDLS Channel Switch Timing element included in the TDLS Channel Switch Request frame shall specify the values required at the STA sending the TDLS Channel Switch Request frame. The SwitchTime and SwitchTimeout values specified in the TDLS Channel Switch Timing element included in the TDLS Channel Switch Response frame shall meet the requirements at the STA sending the TDLS Channel Switch Response frame and shall be equal to or larger than the values specified in the TDLS Channel Switch Request frame. The timing parameters specified in the Channel Switch Timing element included in the TDLS Channel Switch Response frame shall be used for the TDLS channel switching procedure. This procedure causes the larger of the two switch times to become the value that is transmitted in the TDLS Channel Switch Response frame.

The TDLS peer STA shall be in PS mode with the AP and shall not be involved in an active Service Period with the AP before sending a TDLS Channel Switch Request frame or a TDLS Channel Switch Response frame with the Status Code field set to SUCCESS. The TDLS peer STA that receives a TDLS Channel Switch Request frame may enter PS mode with the AP prior to sending the TDLS Channel Switch Response frame.

Because there is at least a backoff between the TDLS Channel Switch Request frame and the TDLS Channel Switch Response frame, there is a (small) probability that two STAs issue a TDLS Channel Switch Request frame at more or less the same time. To reduce the probability for this event to occur, a TDLS peer STA should not transmit a TDLS Channel Switch Request frame when a TDLS Channel Switch Request frame is received and no TDLS Channel Switch Response has been transmitted in response. If a TDLS Channel Switch Request frame is received from the TDLS peer STA to which a pending TDLS Channel Switch Request frame was previously sent before receiving TDLS Channel Switch Response, the TDLS initiator STA shall not reply to the TDLS Channel Switch Request frame and the TDLS responder STA shall reply to the TDLS Channel Switch Request frame.

If a TDLS Channel Switch Response frame does not imply a channel switch because the STAs already are on the requested channel, then the SwitchTime and ProbeTime may be skipped and both TDLS peer STAs continue to operate on the requested channel. To cross means that a TDLS Channel Switch Request frame is received from a peer STA after transmitting a TDLS Channel Switch Request frame to the TDLS peer STA, instead of the expected TDLS Channel Switch Response frame.

When a TDLS peer STA does not receive an acknowledgment to a TDLS Channel Switch Response frame, it may retransmit the frame but the number of retransmissions shall be lesser of the maximum retry limit and dot11TDLSPeerSTAMissingAckRetryLimit.

A channel switch from an off-channel to the base channel may be accomplished by sending a TDLS Channel Switch Response frame indicating the base channel as the target channel, without prior TDLS Channel Switch Request frame. The Channel Switch Timing element shall be the same as contained in the Channel Switch Response frame that caused the switch to the off-channel.

TDLS Channel Switching shall not be used when the TDLS Channel Switching Prohibited subfield included in the Extended Capabilities element of the Association Response frame or Reassociation Response frame that led to the current association is equal to 1.

After moving into a new operating channel, a STA shall perform CCA until a frame is detected by which it can set its NAV, or until a period of time indicated by the NAVSyncDelay parameter from the most recent MLME-START.request or MLME-JOIN.request primitive has transpired.

11.20.6.2 General behavior on the off-channel

If dot11SpectrumManagementRequired is true, a TDLS peer STA shall not transmit a TDLS Channel Switch request specifying an off-channel where radar detection is required, unless the STA has tested that channel for the presence of radar, according to regulatory requirements. If a TDLS peer STA that is operating in such a

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

channel detects radar, the TDLS peer STA shall discontinue transmissions according to regulatory requirements, and it shall send a TDLS Channel Switch Request frame indicating a switch to the base channel. The channel switch avoids an interruption on the TDLS direct link.

The TDLS peer STA initiating the switch to the channel where radar detection is required by regulation shall be the DFS owner.

A secondary channel of an existing network shall not be selected as an off-channel.

On an off-channel, the TDLS peer STAs remain associated with their BSS, so the BSSID remains the same.

It is recommended that in general TDLS STAs propose target channels that have no detectable medium occupancy. If no such channel is available, then it is recommended that the TDLS STA propose a target channel where beacons are detected but with little or no additional medium occupancy. It is further recommended that TDLS STAs do not propose a target channel where the presence of beacons indicate that ACM subfields are set, unless little or no additional medium occupancy is detected.

11.20.6.3 Setting up a 40 MHz TDLS direct link

11.20.6.3.1 General

A 40 MHz off-channel TDLS direct link may be started if both TDLS peer STAs indicated 40 MHz support in the Supported Channel Width Set field of the HT Capabilities element (which is included in the TDLS Setup Request frame and the TDLS Setup Response frame).

Switching to a 40 MHz off-channel TDLS direct link is achieved by including the following information in the TDLS Channel Switch Request frame:

— Operating Class field indicating 40 MHz channel spacing
— Secondary Channel Offset field indicating SCA or SCB

A 40 MHz off-channel TDLS direct link shall not be established in the 2.4 GHz band.

The TDLS peer STA initiating the switch to the 40 MHz off-channel shall be the DO.

11.20.6.3.2 Basic 40 MHz functionality

TDLS peer STAs may transmit 40 MHz PPDUs on a 40 MHz TDLS direct link. A TDLS peer STA shall not transmit a 20 MHz PPDU in the secondary channel of its 40 MHz TDLS direct link.

11.20.6.3.3 Channel selection for a 40 MHz TDLS direct link

If a TDLS peer STA chooses to start a 40 MHz TDLS direct link that occupies the same two channels as an existing 40 MHz network (i.e., a 20/40 MHz BSSs or a 40 MHz TDLS direct link), then it shall select primary and secondary channels of the new direct link that are identical to the primary and secondary channels of the existing 40 MHz network, unless the TDLS peer STA discovers that on these two channels there are existing 40 MHz networks with different primary and secondary channels.

If a TDLS peer STA chooses to start a 40 MHz TDLS direct link, the selected secondary channel should correspond to a channel on which no beacons are detected.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.20.6.3.4 Switching from a 40 MHz to a 20 MHz TDLS direct link

Switching from a 40 MHz off-channel TDLS direct link to a 20 MHz off-channel TDLS direct link is established through a TDLS channel switch. When on a 40 MHz off-channel TDLS direct link, a requested switch to a 20 MHz TDLS direct link shall always be accepted.

11.20.6.3.5 CCA sensing and NAV assertion in a 40 MHz TDLS direct link

When active on a 40 MHz TDLS direct link, a TDLS peer STA shall follow the CCA rules as defined in 11.15.9 and the NAV rules as defined in 11.15.10.

11.20.6.4 TDLS channel switching and power saving

A TDLS direct link shall not be switched to an off-channel during a TPU service period. While on an off-channel, a TDLS peer STA shall not enter TPU power save mode.

A TDLS direct link may be switched to an off-channel when TDLS peer PSM is active on the link. The wakeup windows occur on the off-channel in the same way they would have occurred had the STAs remained on the base channel. Suspension of the wakeup windows implies a switch back to the base channel.

11.20.6.5 Setting up a wide bandwidth off-channel TDLS direct link

11.20.6.5.1 General

A wideband TDLS off-channel TDLS direct link is a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz off-channel TDLS direct link for VHT STAs or 40 MHz off-channel TDLS direct link for HT STAs or a 2 MHz, 4 MHz, 8 MHz, or 16 MHz off-channel TDLS direct link for S1G STAs.

A wideband off-channel TDLS direct link may be started if both TDLS peer STAs indicated wideband support in the VHT Capabilities element, HT Capabilities element or S1G Capabilities element included in the TDLS Setup Request frame or the TDLS Setup Response frame.

Switching to a wideband off-channel TDLS direct link is achieved by including any of the following information in the TDLS Channel Switch Request frame:

— An Operating Class field indicating 40 MHz Channel spacing and a Secondary Channel Offset element indicating SCA or SCB for HT STAs
— A Wide Bandwidth Channel Switch element indicating 80 MHz, 160 MHz, or 80+80 MHz channel width for VHT STAs
— A Wide Bandwidth Channel Switch element indicating 4 MHz, 8 MHz, or 16 MHz channel width for S1G STAs

For VHT STAs, the operating class in TDLS Channel Switch Request frame shall have a value representing 5 GHz for the channel starting frequency.

A TDLS peer STA that is extended spectrum management capable and that announces new TPC parameters that come into effect at the same time as the switch to an off-channel TDLS direct link, shall include at least one Transmit Power Envelope element in the transmitted the TDLS Channel Switch Request frame. The recipient TDLS peer STA that is extended spectrum management capable and that has dot11SpectrumManagementRequired or dot11RadioMeasurementActivated equal to true shall use the parameters in these received element(s) in the recipient STA’s TPC calculations for the off-channel TDLS direct link.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When announcing new operating classes or both a new operating class table index and new operating classes that come into effect at the same time as the switch to the direct link and that express new regulatory requirements, the TDLS peer VHT or S1G STA initiating the switch shall include a Country element in a transmitted TDLS Channel Switch Request frame. The Country element shall contain all of the Operating Classes for the off-channel TDLS direct link in Operating Triplet fields and zero Subband Triplet fields. The Country element shall include one Operating Triplet field that contains the same Operating Class as the Operating Class field in the same frame. The country indicated by the Country string in the TDLS Channel Switch Request frame shall be equal to the country indicated by the Country string of the BSS. The recipient TDLS peer VHT or S1G STA that has dot11MultiDomainCapabilityActivated, dot11SpectrumManagementRequired, or dot11RadioMeasurementActivated equal to true shall use the parameters in the received Country element in the TDLS Channel Switch Request frame in order to maintain regulatory compliance.

The TDLS peer STA initiating the switch to the wideband off-channel shall be the DO on that channel.

11.20.6.5.2 Basic wideband functionality

TDLS peer STAs may transmit up to 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz PPDUs on a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz TDLS direct link, respectively. A TDLS peer STA shall not transmit a 20 MHz PPDU in the nonprimary channel of its 80 MHz, 160 MHz, or 80+80 MHz TDLS direct link.

A TDLS peer STA shall not transmit a 40 MHz PPDU that does not use the primary 40 MHz channel of its 80 Hz, 160 MHz, or 80+80 MHz TDLS direct link. A TDLS peer STA shall not transmit an 80 MHz PPDU that does not use the primary 80 MHz channel of its 160 MHz or 80+80 MHz TDLS direct link.

TDLS peer S1G STAs may transmit up to 4 MHz, 8 MHz, or 16 MHz PPDUs on a 4 MHz, 8 MHz, or 16 MHz off-channel TDLS direct link, respectively. An S1G STA determines the channelization based on the Wide Bandwidth Channel Switch element of the TDLS Channel Switch Request frame.

A TDLS peer S1G STA shall not transmit a 1 MHz PPDU in the nonprimary 1 MHz channel of its 4 MHz, 8 MHz or 16 MHz off-channel TDLS direct link. A TDLS peer S1G STA shall not transmit a 2 MHz PPDU in the nonprimary 2 MHz channel of its 4 MHz, 8 MHz, or 16 MHz off-channel TDLS direct link. A TDLS peer S1G STA shall not transmit a 4 MHz PPDU that does not use the primary 4 MHz channel of its 8 MHz or 16 MHz off-channel TDLS direct link. A TDLS peer S1G STA shall not transmit an 8 MHz PPDU that does not use the primary 8 MHz channel of its 16 MHz off-channel TDLS direct link.

11.20.6.5.3 Channel selection for a wideband off-channel TDLS direct link

If a non-S1G TDLS peer STA chooses to start a wideband TDLS direct link, the TDLS peer STA shall follow the primary channel selection rules defined in 11.38.2 and 11.21.15 and the secondary 80 MHz channel rule defined in 11.20.1.

If an S1G TDLS peer STA chooses to start a wideband TDLS direct link, the TDLS peer STA shall follow the primary channel selection rules defined in 10.45.4 and 11.21.15.

11.20.6.5.4 Switching from a wideband to a 20 MHz, 1 MHz, or 2 MHz TDLS direct link

Switching from a wideband off-channel TDLS direct link to a 20 MHz, 1 MHz, or 2 MHz off-channel TDLS direct link is established through a TDLS channel switch. A non-S1G STA operating on a wideband off-channel TDLS direct link shall accept a requested switch to a 20 MHz TDLS direct link. An S1G STA operating on a wideband off-channel TDLS direct link shall accept a requested switch to 1 MHz or 2 MHz TDLS direct link.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.20.6.5.5 CCA sensing and NAV assertion in a 20 MHz, 40 MHz, 80 MHz, 160 MHz, 80+80 MHz, 1 MHz, 2 MHz, 4 MHz, 8 MHz, or 16 MHz TDLS direct link

TDLS peer VHT STAs shall follow the CCA rules defined in 10.3.2.7, 10.23.2.8, and 10.23.3 and the NAV rules defined in 11.38.5.

TDLS peer S1G STAs shall follow the CCA rules defined in 10.3.2.7 and 10.23.2.8 and the NAV rules defined in 10.45.6.

11.21 Wireless network management procedures

11.21.1 Wireless network management dependencies

When dot11WirelessManagementImplemented is true, the STA is a WNM STA and dot11ExtendedChannelSwitchActivated and dot11RadioMeasurementActivated shall be true. This subclause describes WNM procedures for requesting and reporting WNM capabilities between STAs that support WNM procedures.

When dot11WirelessManagementImplemented is true, and one or more of bit 7 to bit 27 in the Extended Capabilities element have the value 1, the Extended Capabilities element shall be included in Beacon frames, Association Request and Response frames, Reassociation Request and Response frames, and Probe Request and Response frames. When dot11WirelessManagementImplemented is true, for each bit 7 to bit 27 in the received Extended Capabilities element that is 0, a STA shall not request the corresponding feature from the sending STA. A WNM STA receiving a request for a WNM feature from another STA shall reject the request if the receiving WNM STA has not advertised support for the corresponding WNM feature.

11.21.2 Event request and report procedures

11.21.2.1 Event request and event report

The Event Request and Event Report frames enable network real-time diagnostics. A STA with dot11EventsActivated equal to true shall support event requests and reports and shall set to 1 the Event field of the Extended Capabilities elements that it transmits. If dot11EventsActivated is true and the Event Type field is neither BSS Color Collision nor BSS Color In Use, a STA shall log all Transition, RSNA, peer-to-peer, and WNM log events, including the corresponding TSF, UTC Offset, and Event Time Error. An HE STA that has dot11EventsActivated equal to true and reports BSS color collisions shall log all BSS color collision events, including the TSF value when the STA finished logging the events that are reported (see Table 11.21.2.7).

A STA with either dot11AutonomousBSSColorCollisionReportingImplemented equal to true or dot11AutonomousBSSColorInUseReportingImplemented equal to true shall set the Event field of the Extended Capabilities elements that it transmits to 1.

The STA log of events shall not be cleared as a result of BSS transitions. However, if the STA moves to a different ESS or IBSS, the STA shall delete all event log entries.

A STA that supports event reporting may send an Event Request or Event Report frame to a STA within the same infrastructure BSS or the same IBSS whose last received Extended Capabilities element contained a value of 1 for the Event bit in the Extended Capabilities field; it shall not send an Event Request or Event Report frame otherwise. If the STA receives an Event Request frame without error and it supports event reporting, it shall respond with an Event Report frame that includes a Dialog Token field that matches the one in the Event Request frame.

The permitted source and destination STAs for an Event Request frame are shown in Table 11-13.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An AP may include zero or more Event Request elements in an Event Request frame. Each Event Request element contains an Event Token that associates this Event Request with any subsequent Event Report elements. When sending Event Report elements, a STA shall use the same Event Token that was included in the original request.

Only a single Event Request frame from a STA is outstanding at a given STA at any time. If a STA that supports event reporting receives a subsequent Event Request frame with a different dialog token before completing the Event Report for the previous request from the requesting STA, the receiving STA may respond to the most recent request frame; it shall not respond to a request frame that is not the most recent one.

Upon a BSS transition, the STA shall cancel any event requests in the latest Event Request frame.

The Event Request elements can contain conditions that specify events to be reported and conditions that establish event reporting when a STA experiences problems or failures. A STA sends an Event Request frame containing one or more Event Request elements, each of which contains zero or more subelements. Subelements are defined for each event type. A STA shall include in the corresponding Event Report element only those events that meet the specified event conditions within the ESS or IBSS of which the transmitting STA is a member.

In each Event Report element, a STA shall include a Status field that indicates the result of the event request/report transaction. If the STA is able to return one or more Event Report elements, then the STA shall return a value of "Successful" in the Event Report element. If the STA has no logged events of the requested type, the STA shall return a value of Successful in the Event Report element without an event included in the Event Report field. If the STA is unable to process the request at that time, the STA shall return a value of "Request failed" in the Event Report element. If a STA refuses an event request, the STA shall return a value of "Request refused" in the Event Report element. The reasons for refusing an event request are outside the scope of this standard but may include reduced quality of service, unacceptable power consumption, measurement scheduling conflicts, or other significant factors. If the STA is incapable of generating an Event Report of the type specified in the Event Request frame, the STA shall return a value of "Request incapable" indicating that the requester should not request again.

If the Event Report elements do not fit into a single MMPDU, the reporting STA shall send the remaining elements in additional Event Report frames until all Event Report elements have been returned to the requesting STA. In any subsequent Event Report frame and for all remaining Event Report elements a reporting STA shall include the same values of the Dialog Token and Event Token fields, respectively, that was sent in the corresponding Event Request frame. When multiple MMPDUs are required, the non-AP STA shall include complete Event Report elements and shall not fragment an element across multiple MMPDUs.

A STA shall transmit both the Event Request frame and the Event Report frame only with a destination address that is an individual address. In an infrastructure BSS, only an AP shall transmit an Event Request frame to a non-AP STA. An AP that supports event reporting shall discard received Event Request frames.

When a STA transmits an Event Request frame to another STA it shall indicate the types of events requested by setting the Event Type field and shall indicate the maximum number of logged events to report by using the Event Response Limit field in each included Event Request element. If the number of available logged events of the requested type exceeds the Event Response Limit, the STA shall report an Event Response Limit number of the most recent events. If there are no available logged events of the type specified in the Event Request frame, the STA shall send the Event Report frame without any Event Report element. The reporting STA shall send all available Event Report elements for the requested event type when the Event Request field is not present in the Event Request element.

A STA may include a Destination URI element in the Event Request frame. The AP includes the URI in the Destination URI element that the reporting non-AP STA may use to send Event Reports, upon the loss or interruption of connectivity to the BSS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

On receipt of an Event Request frame with an Destination URI element, the reporting non-AP STA SME may send the Event Report to the AP using the Destination URI with another network interface (if available). The non-AP STA SME shall not send the Event Report to the URI contained in the Destination URI element except after detecting loss of BSS connection.

The non-AP STA shall determine loss of connection to the AP that issued the Event Request frame when it has not detected any Beacon frames from the AP for a period no less than the ESS detection interval.

If the BSS connection is reestablished to the AP that transmitted the Event Request frame, the non-AP STA shall transmit the corresponding Event Report frame to the AP without using the Destination URI.

When the non-AP STA uses the Destination URI mechanism, it shall transport the Frame Body field of the Event Report frame using the URI given in the Destination URI Element. An example use of the Destination URI is given in Annex Q.

11.21.2.2 Transition event request and report

The Transition Event report provides information on the previous transition events for a given non-AP STA. The Transition Event request and report are only permitted in the infrastructure BSS.

Each STA supporting the Transition Event shall log up to the last five Transition events occurring since the STA associated to the ESS. A STA may log more than five of the most recent Transition events.

Upon receipt of an Event Request frame containing an Event Request element including a Transition Event request, the non-AP STA shall respond with an Event Report frame that includes available Event Report elements within the ESS of which the transmitting STA is a member for the Transition event type.

Transition Event Request subelements are used to specify conditions for reporting of transition events. If any Transition Event Request subelements are present in the Event Request frame, the reporting non-AP STA shall include in the Event Report frame only those available Transition Event Report elements that meet the transition event reporting condition(s) specified in the Event Request frame. If no transition event subelements are present in the Event Request field, the reporting STA shall include all available Transition Event Report elements.

A Frequent Transition subelement in an Event Request frame defines conditions for frequent transition. Frequent transition occurs when the number of BSS transitions exceeds the frequent transition count threshold within the indicated time interval as defined in the Frequent Transition subelement in 9.4.2.65.2. A STA that receives a Frequent Transition subelement shall, at each BSS transition, apply the conditions for frequent transition to the log of transition events. If the logged transition events meet the conditions for frequent transition, the STA shall send an Event Report frame including a Transition Event Report element with Event Report Status set to Detected Frequent Transition and include in that Event Report element the last logged transition event.

For transition logging and reporting purposes, the transition time is defined as the time difference between the starting time and the ending time of a transition between APs, even if the transition results in remaining on the same AP.

The starting time is one of the following items:

— The start of a search for an AP, when the transition reason is 4 (first association to WLAN).
— The latest time that a frame could have been transmitted or received on the source BSS.
— The start of a search for an AP, after determination that a transition has failed.

The ending time is one of the following items:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The earliest time that a Data frame can be transmitted or received on the target BSS, after completion of RSN, IEEE 802.1X, or other authentication and key management transmissions, when such are required by the target BSS.
— The time that a determination is made that the transition has failed.

11.21.2.3 RSNA event request and report

The RSNA Event Report provides authentication events for a given non-AP STA. The RSNA Event Request and Report are only permitted in an infrastructure BSS.

Each STA supporting the RSNA Event shall log up to the last five RSNA events occurring since the STA associated to the ESS. A STA may log more than five of the most recent RSNA events.

Upon receipt of an Event Request frame containing an Event Request element including an RSNA Event request, the non-AP STA shall respond with an Event Report frame that includes available Event Report elements within the ESS of which the transmitting STA is a member for the RSNA event type.

If an RSNA Event Request subelement is present in the Event Request field, the reporting non-AP STA shall include available Event Report elements that meet the specified condition for the RSNA event type. If no RSNA Event Request subelement is present in the Event Request field, the reporting STA shall include all available RSNA Event Report elements.

11.21.2.4 Peer-to-peer link event request and report

The peer-to-peer link event report provides peer-to-peer connectivity events for a given non-AP STA. A peer-to-peer event occurs when a peer-to-peer link is initiated or terminated.

Each STA supporting the peer-to-peer link event shall log up to the last five peer-to-peer link events occurring since the STA associated to the ESS or IBSS. A STA may log more than five of the most recent peer-to-peer link events. When a link is initiated, a STA shall log and record the TSF time of the peer-to-peer link event without a connection time. When a peer-to-peer link is terminated, a STA shall log the peer-to-peer link event including the connection time for the terminated link and shall delete from the log any initiation event for the same peer-to-peer link.

Upon receipt of an Event Request frame containing an Event Request element including a peer-to-peer link event request, the non-AP STA shall respond with an Event Report frame that includes available Event Report elements within the ESS or IBSS of which the transmitting STA is a member for the Peer-to-peer event type. When a STA includes a Peer-to-Peer Link Event Report element for a link initiation, the STA shall include a connection time for the event report element which indicates the time difference from the event timestamp to the current time.

If a Peer-to-Peer Link Event Request subelement is present in the Event Request field, the reporting non-AP STA shall include available Event Report elements that meet the specified condition for the Peer-to-peer event type. If no Peer-to-Peer Link Event Request subelements are present in the Event Request field, the reporting STA shall include all available Peer-to-Peer Link Event Report elements.

11.21.2.5 WNM log event request and report

The WNM log event report is intended to capture PHY and MAC events in vendor-specific, human-readable (ASCII text) form. The WNM log is a general reporting mechanism that can apply to configuration or monitoring behavior for PHY and MAC. The WNM log is particularly useful for logging success or failure events across areas such as driver status, IEEE 802.11 or IEEE 802.1X authentication, authorization, status changes while associated or unassociated.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

For example:
<0>Oct 03 17:47:00 00:01:02:03:04:05 Adapter DLL Service initialized
<1>Oct 03 17:48:40 00:01:02:03:04:05 Authentication started
<1>Oct 03 17:48:46 00:01:02:03:04:05 IEEE 802.1X Authentication Failed, credential failure
<1>Oct 03 17:49:00 00:01:02:03:04:05 Authentication success

A non-AP STA that supports event reporting may be queried at any time for its current set of WNM log messages. The WNM log messages returned by the non-AP STA may provide insight into the trouble being experienced by non-AP STA.

Upon receipt of an Event Request frame containing an Event Request element including a WNM log event request, the non-AP STA shall respond with an Event Report frame that includes WNM Log Event Report elements.

11.21.2.6 Vendor Specific event request and report

The procedures for use of the Vendor Specific Event Request and Report are vendor specific and are not part of this standard.

11.21.2.7 BSS color collision event

The BSS color collision event report enables a non-AP HE STA to inform its associated AP whether a BSS color collision has occurred. The report carries information about the BSS color used by OBSSs that the reporting STA is able to detect (see 26.17.3.5.2).

11.21.2.8 BSS color in use event

If a non-AP HE STA communicates with a peer STA with a BSS color that is different from the BSS color used by its associated AP, the non-AP HE STA may send a BSS color in use event report to its associated AP in which the Event Report field has the BSS color used in the communication with the peer STA.

A non-AP HE STA shall send a BSS color in use event report to its associated AP with the Event Report field set to 0 to cancel a previously sent BSS color in use event report.

An AP shall not transmit frames to a non-AP HE STA during a TXOP, if it has received a BSS color in use event report from that non-AP HE STA with a nonzero BSS color in the Event Report field and the AP discards an inter-BSS PPDU with the same BSS color value as the one carried in the Event Report field to obtain a TXOP by following the procedure in 26.10.2.2 and 26.10.2.3.

11.21.3 Diagnostic request and report procedures

11.21.3.1 Diagnostic request and diagnostic report

The Diagnostic Request and Diagnostic Report protocol provides a tool to diagnose and debug complex network issues. A STA with dot11DiagnosticsActivated equal to true shall support diagnostic reporting and shall set to 1 the Diagnostics field of the Extended Capabilities elements that it transmits.

A STA that supports diagnostics reporting shall send a Diagnostics Request or Diagnostics Report frame to a STA within the same infrastructure BSS or the same IBSS whose last received Extended Capabilities element contained a value of 1 for the Diagnostics bit in the Extended Capabilities field; it shall not send a Diagnostics Request or Diagnostics Report frame otherwise.

The Diagnostic Request frame contains a unique Dialog Token. A value of 0 for the Dialog Token field is a reserved and shall not be used. The source and destination of a Diagnostic Request frame shall both be

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

members of the same BSS. The permitted source and destination STAs for a Diagnostic Request frame are shown in Table 11-13. A STA may include one or more Diagnostic Request elements in a Diagnostic Request frame. Each Diagnostic Request element contains a unique Diagnostic Token that identifies the element within the Diagnostic Request frame.

If a STA that supports diagnostic reporting receives a Diagnostic Request frame without error, the STA shall respond with a Diagnostic Report frame that includes a Dialog Token field that matches the one in the Diagnostic Request frame. Each Diagnostic Report element that corresponds to the Diagnostic Request element shall contain the same Diagnostic Token that was included in the original request.

Only a single Diagnostic Request frame from a STA is outstanding at a given STA at any time. If a STA receives a subsequent Diagnostic Request frame with a different dialog token before completing the Diagnostic Report for the previous request from the requesting STA, the STA shall respond to the most recent Diagnostic Request frame; the STA shall not respond to a Diagnostic Request frame that is not the most recent one.

All outstanding diagnostic requests, as indicated by received MLME-DIAGREQUEST.indication primitives, are canceled upon a BSS transition, except when the BSS transition occurs as a result of responding to or initiating a diagnostic request. All outstanding diagnostic requests, as indicated by received MLME-DIAGREQUEST.indication primitives, shall be canceled by the SME after the time indicated in the Diagnostic Timeout field, in the Diagnostic Request frame. When a STA that supports diagnostic reporting receives a Diagnostic Request frame with a Diagnostic Request Type of Cancel Diagnostic Request, the SME shall cancel all outstanding diagnostic requests, and discard all pending diagnostic reports, as indicated by received MLME-DIAGREQUEST.indication primitives.

All Diagnostic Report elements shall include a Status field that indicates the overall result of the transaction. If the STA is able to complete the diagnostic request made in the Diagnostic Request element, then a value of "Successful" shall be returned. If the STA is unable to process the request at that time a value of "Fail" shall be returned. If the STA is incapable of generating a report of the type specified, it shall return a value of "Incapable." If the STA cannot support the request for any other reason, the value of Refused shall be returned.

A STA shall transmit both the Diagnostic Request frame and the Diagnostic Report frame with a destination address that is an individual address.

A STA may include a Destination URI element in the Event Request frame. The AP includes the URI in the Destination URI element that the reporting non-AP STA may use to send Diagnostic Reports, upon the loss or interruption of connectivity to the BSS.

On receipt of an Diagnostic Request frame with an Destination URI element, the reporting non-AP STA SME may send the Diagnostic Report to the AP using the Destination URI with another network interface (if available).

The non-AP STA shall determine loss of connection to the AP that issued the Diagnostic Request frame when it has not detected any Beacon frames from the AP for a period no less than the ESS detection interval.

If the BSS connection is reestablished to the AP that transmitted the Diagnostic Request frame, the non-AP STA shall transmit the corresponding Diagnostic Report frame to the AP without using the Destination URI.

When the non-AP STA uses the Destination URI mechanism, it shall transport the payload of the Diagnostic Report frame using the URI given in the Destination URI Element. An example use of the Destination URI is given in Annex Q.

If a non-AP STA that receives an Destination URI subelement in an Diagnostic Request fails to detect any Beacon frames, belonging to the AP that issued the request for a Diagnostic report, for the period specified by

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the ESS detection interval, it may use the URI specified in the Destination URI subelement to transport the Diagnostic Report to the AP.

If the Diagnostic Report elements do not fit into a single MMPDU, the reporting STA shall send the remaining elements in additional frames until all Diagnostic Report elements have been returned to the requesting STA. A STA shall include the same values of the Dialog Token and Diagnostic Token fields that were transmitted in the corresponding Diagnostic Request frame in each subsequent Diagnostic Report frame and Diagnostic Report elements. When multiple MMPDUs are required, the STA shall include complete Diagnostic Report elements and shall not fragment an element across multiple MMPDUs.

A STA that supports diagnostic reporting may cancel a previously sent Diagnostic Request frame for which it has not yet received a Diagnostic Report frame by sending a Diagnostic Request frame with the Diagnostic Request Type field value of 0, indicating "Canceled," to the STA to which it previously sent the Diagnostic Request frame. A STA that supports diagnostic reporting shall inform a STA from which it has previously received a Diagnostic Request frame that the request has been locally canceled by sending a Diagnostic Report frame with the Diagnostic Status field set to a value of 4, indicating "Canceled," to the requesting STA. In a Diagnostic Request frame with the Diagnostic Request Type field value of 0, and a Diagnostic Report frame with the Diagnostic Status field set to a value of 4, no Diagnostic subelements are included in the Diagnostic Request or Response element.

11.21.3.2 Configuration Profile report

The Configuration Profile report enables an AP to discover the current profile in use for an associated STA, and additional profiles for the ESS of which the STA is a member. A non-AP STA that supports diagnostic reporting and receives a Configuration Profile report request type shall respond with a Diagnostic Report frame that includes all available Diagnostic elements allowed for the type.

STAs that support multiple configuration profiles for an ESS may include multiple Diagnostic Report elements in a single Diagnostic Report frame (or multiple frames if required). Each Diagnostic Report element shall contain a Profile ID element that uniquely identifies the configuration profile(s) for the ESS of which the STA is a member that are available on the device.

11.21.3.3 Manufacturer information STA report

The Manufacturer Information STA Report enables an AP to discover static manufacturer specific data about an associated STA. A non-AP STA that supports diagnostic reporting and receives a Manufacturer Information STA Report request type shall respond with a Diagnostic Report frame that includes all available Diagnostic elements allowed for the type.

When more than one Antenna Type/Antenna Gain pair is enabled, multiple Antenna Type subelements shall be included in the Manufacturer Information STA Report Diagnostic Report element.

When more than one Colocated Radio Type, or Device Type is supported, multiple Colocated Radio Type subelements, or Device Type subelements shall be included in the Manufacturer Information STA Report Diagnostic Report element. If the existence or the type of colocated radio is unknown, no Colocated Radio Type subelements shall be included.

11.21.3.4 Association diagnostic

The purpose of the association diagnostic is to determine that a STA is able to associate with a designated BSS. This test directs an association to be completed with a specific AP.

To initiate the test, an AP that supports diagnostic reporting shall send a Diagnostic Request frame containing a Diagnostic Request Type field set to 3 (i.e., Association Diagnostic) to a STA that supports diagnostic

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

reporting. The AP shall not send an association diagnostic request with a designated BSS that is not part of the ESS and the STA receiving an association diagnostic request shall reject requests to perform diagnostics on a BSS that is not part of the ESS. All parameters required to complete the association are included in the Diagnostic Request element.

Upon receipt of the Diagnostic Request frame containing a Diagnostic Request element specifying an association request, the STA determines whether to accept the request. If the STA declines the request, it shall send a Diagnostic Report frame with the Status field of a Diagnostic Report element set to Refused. If the STA accepts the request, it shall cause an authentication to occur to the AP indicated in the Diagnostic Request element and the STA's SME shall issue an MLME-DIAGREPORT.request primitive, indicating the results of the diagnostic.

One means to cause an authentication to occur is for the STA's SME to issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the current AP, and an MLME-AUTHENTICATE.request primitive to authenticate to the AP indicated in the Diagnostic Request element. If successful, the STA shall issue an MLME-(RE)ASSOCIATE.request primitive to associate with the AP indicated in the Diagnostic Request element. If successful, the STA's SME shall then issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the AP indicated in the Diagnostic Request element, reassociate with the AP from which it received the Diagnostic Request, and issue an MLME-DIAGREPORT.request primitive, indicating the results of the diagnostic.

11.21.3.5 IEEE 802.1X authentication diagnostic

The purpose of the IEEE 802.1X authentication diagnostic is to determine that the STA is able to complete an IEEE 802.1X authentication with a designated BSS. This test directs an association and IEEE 802.1X authentication to be completed with a specific AP. If a STA that supports diagnostic reporting also supports RSN, the STA shall support the IEEE 802.1X authentication diagnostic.

To initiate the test, an AP that supports diagnostic reporting shall send a Diagnostic Request frame containing a Diagnostic Request Type field set to 4 (i.e., IEEE 802.1X Authentication Diagnostic) to a STA that supports diagnostic reporting. A STA that supports diagnostic reporting in an IBSS or an AP that supports diagnostic reporting shall not send an IEEE 802.1X authentication diagnostic request with a designated BSS that is not part of the ESS, or IBSS and a STA that supports diagnostic reporting which receives a diagnostic request shall reject requests to perform diagnostics on other networks. The AP, EAP method and credential type values included in the AP Descriptor, EAP Method and Credential Type subelements in the Diagnostic Request element shall be used to complete the association and IEEE 802.1X authentication.

Upon receipt of the Diagnostic Request frame containing a Diagnostic Request element specifying an IEEE 802.1X Authentication Diagnostic request, the STA determines whether to accept the request. If the STA declines the request, it shall send a Diagnostic Report frame with the Status field of a Diagnostic Report element set to Refused. If the STA accepts the request, it shall cause an IEEE 802.1X authentication to occur to the AP indicated in the Diagnostic Request element and the STA's SME shall issue an MLME-DIAGREPORT.request primitive indicating the results of the diagnostic.

One means to cause an authentication to occur is for the STA's SME to issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the current AP, and an MLME-AUTHENTICATE.request primitive to authenticate to the AP indicated in the Diagnostic Request element. If successful, the STA shall issue an MLME-(RE)ASSOCIATE.request primitive to the AP indicated in the Diagnostic Request element. If (re)association succeeds, the STA shall try to complete IEEE 802.1X authentication using parameters specified in the Diagnostic Request element. The STA shall then issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the AP indicated in the Diagnostic Request element, reassociate with the AP from which it received a diagnostic request, and issue an MLME-DIAGREPORT.request primitive, indicating the results of the diagnostic.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.21.4 Location track procedures

11.21.4.1 Location track configuration procedures

A STA with dot11LocationTrackingActivated equal to true shall support location tracking and shall set to 1 the Location field of the Extended Capabilities elements that it transmits.

In an infrastructure BSS, a non-AP STA shall not transmit Location Configuration Request frames.

A STA that supports location may configure another STA to transmit Location Track Notification frames for the purpose of tracking the receiving STA's location by sending Location Indication Channels, Location Indication Interval and Location Indication Broadcast Data Rate subelements in a Location Parameters element in a Location Configuration Request frame. The minimum Normal and In-Motion Report Interval in a Location Configuration Request frame is 500 ms.

A STA may transmit the Location Configuration Request frame as a broadcast or individually addressed frame. A STA that supports location and receives a broadcast Location Configuration Request frame shall send a Location Configuration Response frame if the STA does not accept the parameters included in the Location Configuration request; the STA shall not send a Location Configuration Response frame if it accepts the parameters included in the Location Configuration request.

A STA that supports location and receives an individually addressed Location Configuration Request frame shall respond with a Location Configuration Response frame. Upon reception of a new Location Configuration Request frame, the STA shall override any information from a previously received Location Configuration Request frame with the new frame. If all Location Parameter subelements included in the Location Configuration Request frame are successfully configured on the receiving STA, then the STA shall include in the Location Configuration Response frame a single Location Status subelement indicating success. Upon successful configuration, the receiving STA shall start transmitting the Location Track Notification frames based on the Location Configuration Request frame parameters, as described in 11.21.4.2. If one or more Location Parameter subelements are unsuccessfully configured, then the STA shall include in the Location Configuration Response frame a Location Status subelement for each failed subelement indicating the subelement ID, the status value and the corresponding Location Parameter subelement as described in the paragraphs that follow.

The Location Status subelement has four possible status values: Success, Fail, Refused and Incapable. When the requesting STA receives a Location Configuration Response frame with Location Status indicating anything other than Success, the requesting STA shall assume the original request was not processed and no configuration took effect on the receiving STA and the requesting STA should take appropriate action based on the status value returned.

For Location Status Fail:

— If the receiving STA has been configured successfully prior to the current Location Configuration Request and continues to transmit Location Track Notification frames based on those parameters, the STA shall respond with its current Location Parameters subelements values.
— If the STA has no previously configured value, the STA shall respond with its minimum Location Parameters subelements that it is capable of supporting.
— The configuring STA may either retry the original request or send an alternate request.

For Location Status Incapable:

— The STA responding to the configuration request may include the minimum Location Parameters subelements that it is capable of supporting.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The configuring STA shall not send another configuration request matching the previous configuration request while the reporting STA is a member of the same BSS.
— The configuring STA may send an alternate request.

For Location Status Refuse:

— The STA responding to the configuration request may include the minimum Location Parameters subelements that it is capable of supporting.
— The configuring STA may send an alternate request.

The location configuration methods, from highest to lowest precedence, are as follows: 1) an individually addressed Location Configuration Request frame, 2) broadcast Location Configuration Request frame. When a STA receives a new Location Configuration frame at the same or higher precedence than the previous it shall cancel the previous configuration and begin using the newest configuration.

The Location Indication Broadcast Data Rate subelement included in Location Configuration Request frames indicates the target data rate at which the STA shall transmit Location Track Notification frames. The Location Indication Broadcast Data Rate included in the Location Configuration Request frame should be a data rate defined in the basic data rate set.

The Indication Multicast Address field configured in the Location Indication Parameters subelement shall be a multicast locally administered MAC address as defined in IEEE Std 802 that is shared across all APs in the same ESS. The STA shall transmit Location Track Notification frames to the Indication Multicast Address with the BSSID field set to the wildcard BSSID. An AP shall discard Location Track Notification frames that are not addressed to the Indication Multicast Address field configured for the ESS.

A non-AP STA shall terminate the transmission of Location Track Notification frames for any of the following reasons:

— The non-AP STA receives a Location Configuration Request frame from the STA to which it is currently associated that includes a Location Parameters element with a Location Indication Parameters subelement specifying an interval of 0.
— The non-AP STA fails to detect any Beacon frames, belonging to the same ESS that originally configured the non-AP STA, for the period specified by the ESS detection interval value included in the Location Parameters element transmitted in the Location Configuration Request frame.
— dot11LocationTrackingActivated is false.
— The non-AP STA is disassociated for any reason from the ESS that configured it, including power off, or is configured by a different ESS.
— In an IBSS when the STA detects that it is no longer connected to the other STA that formed the IBSS.

NOTE—All Public Action frames, including the Location Track Notification frames, are Class 1 frames and the treatment of Public Action frames upon reception by STAs is defined in 11.3.

11.21.4.2 Location track notification procedures

Implementation of location track notification is optional for a WNM STA. A STA that implements location track notification has dot11LocationTrackingImplemented equal to true. When dot11LocationTrackingImplemented is true, dot11WirelessManagementImplemented shall be true. A STA in which dot11LocationTrackingActivated is true is defined as a STA that supports location track notification.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When location track notification is supported, a STA configured by another STA as described in the previous subclause shall transmit Location Track Notification frames as shown in Figure 11-39 .

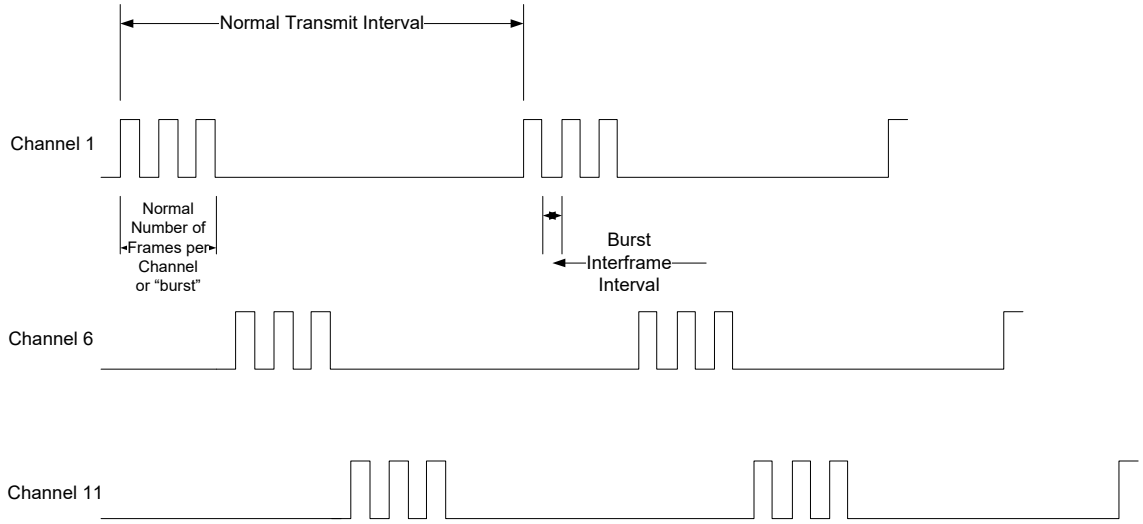

Figure 11-39—STA transmission on three channels, three frames per channel with Normal Report Interval

Implementation of Motion Detection or the Time of Departure reporting is optional for a WNM STA. A STA that implements motion detection shall set dot11MotionDetectionImplemented to true. When dot11MotionDetectionImplemented is true, dot11WirelessManagementImplemented shall be true. A STA with dot11MotionDetectionActivated equal to true shall support motion detection. A STA that implements the time of departure capability shall set its dot11TODImplmented to true. When dot11TODImplemented is true, dot11WirelessManagementImplemented shall be true. A STA with dot11TODActivated equal to true shall support time of departure for location tracking.

The STA transmits Location Track Notification frames based on the following parameters and procedures described in 11.21.4.1:

a) Location Indication Channels. This subelement indicates the channels on which the STA shall transmit Location Track Notification frames.

b) Indication Multicast Address

   1) A non-IBSS STA shall transmit the Location Track Notification frames to the Indication Multicast Address field in the Location Indication Parameters subelement configured by the Location Configuration Request frame.

   2) An AP shall discard any Location Track Notification frame received from a STA that does not match the Indication Multicast Address field value for the AP's ESS.

   3) An IBSS STA shall transmit the Location Track Notification frames to the destination address of the STA that configured the STA using Location Configuration Request frames.

c) Location Indication Interval

   1) When the STA is stationary or dot11MotionDetectionActivated is false, the STA shall transmit a sequence of groups of Location Track Notification frames on each channel. Each group of frames shall contain Normal Number of Frames Per Channel field frames. The first frame in each group of Location Track Notification frames shall be separated from the first frame in the previous group of Location Track Notification frames by a minimum duration indicated by the value of the Normal Report Interval field times the value of the Normal Report Interval Units field.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

2) When the STA is in motion and dot11MotionDetectionActivated is true, the STA shall transmit a sequence of groups of Location Track Notification frames on each channel. Each group of frames shall contain In-Motion Number of Frames Per Channel field frames. The first frame in each group of Location Track Notification frames shall be separated from the first frame in the previous group of Location Track Notification frames by a minimum duration indicated by the value of the In-Motion Report Interval field times the value of the In-Motion Report Interval Units field.

NOTE 1—The exact criteria and mechanism to detect motion is out of scope for this standard.

3) If a STA is configured to transmit on multiple channels, the STA shall transmit the frames on a single channel before continuing onto the next channel in the configured list of channels.

4) All Location Track Notification frames transmitted on a single channel shall be transmitted with a minimum gap specified by the Burst Interframe Interval field.

5) A STA can never be stationary and in-motion at the same time, and therefore only the Normal Interval field or the In-Motion Interval field apply at any given moment.

d) Tracking Duration

1) The STA shall transmit Location Track Notification frames until the Tracking Duration duration is reached.

2) The duration starts as soon as the STA sends a Configuration Location Response frame with a Location Status value of Success.

3) If the Tracking Duration is a nonzero value the STA shall transmit Location Track Notification frames, based on the Normal and In-Motion Report Interval field values, until the duration ends or is configured to terminate transmission as described in 11.21.4.1.

4) If the Tracking Duration is 0 the STA shall continuously transmit Location Track Notification frames as defined by Normal and In-Motion Report Interval field values until configured to terminate transmission as described 11.21.4.1.

e) ESS Detection

1) The ESS Detection Interval field is specified in the Location Indication Parameters subelement configured by the Location Configuration Request frame. The ESS detection interval defines how often the STA should check for beacons transmitted by one or more APs belonging to the same ESS that configured the STA.

2) If no beacons from the ESS are received during this interval, the STA shall terminate transmission of Location Track Notification frames.

f) Location Indication Options

1) The RM Enabled Capabilities element contained in (Re)Association Request frames indicates the STA's ability to perform radio measurements as described in 9.4.2.43. The Location Indication Options subelement Options Used field Beacon Measurement Mode Used bit shall be set to 0 by the AP when the RM Enabled Capabilities element bits (defined in Table 9-218), Beacon Passive Measurement Capability Enabled, Beacon Active Measurement Capability Enabled and Beacon Table Measurement Capability Enabled are all set to 0. If any of RM Enabled Capabilities element bits Beacon Passive Measurement capability enabled, Beacon Active Measurement Capability Enabled or Beacon Table Measurement Capability Enabled are equal to 1 then the Location Indication Options subelement Options Used field Beacon Measurement Mode Used bit may be set to 1.

2) If the Location Indication Options subelement is included and the Options Used field with the Beacon Measurement Mode Used bit equal to 1 in the most recently received Location Configuration Request frame, the STA shall include in the Location Track Notification frames, the result of the most recent successful beacon measurement that was performed using the requested Beacon Measurement Mode contained in the Location Indications Options subelement.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

3) If the STA has never performed a successful beacon measurement using the requested Beacon Measurement Mode prior to transmission of the Location Track Notification frame, the STA shall perform the beacon measurement using the requested Beacon Measurement Mode and include the results of that measurement in Location Track Notification frames.

4) After a successful Location Configuration Request frame that included the Location Indication Options subelement and Options Used field with Beacon Measurement Mode Used bit equal to 1, a STA should continue to perform beacon measurement as defined by the Beacon Measurement Mode periodically. How often and under what circumstances the STA performs this measurement is out of scope of this standard.

5) Whenever a STA includes the beacon measurement in the Location Track Notification frames, the STA shall set the Measurement Token field in the Measurement Report element to the same value as the Dialog Token field in the Location Configuration Request frame that initiated the transmission of the location track notification frames by the STA.

6) If the Location Indication Options subelement is not included in the most recently received Location Configuration Request frame or the Location Indication Options subelement is included with the Options Used field with Beacon Measurement Mode Used bit equal to 0, the STA shall not include any beacon measurements in the Location Track Notification frame

g) Location Indication Broadcast Data Rate. The STA shall transmit Location Track Notification frames at the data rate specified in this subelement.

h) Time of Departure

1) If dot11TODActivated is true, the STA shall transmit this subelement in the Location Track Notification frame.

2) In all location tracking frames transmitted by a STA following a successful configuration, the Time of Departure subelement TOD Clock Rate field shall be set to the same value.

3) If the STA has multiple antennas, it shall transmit using an approximation to an omnidirectional pattern.

NOTE 2—The values of the fields in the Time of Departure subelement are measured by the PHY in real time, then passed without real-time requirements to the MAC via the TXSTATUS parameter list in the PHY-TXSTART.confirm primitive.

The diagram in Figure 11-39 shows an example of Location Track Notification frame transmission, for a STA configured to transmit on three channels, with three frames per channel. In this example, a Normal Transmit Interval and Normal number of frames per channel are shown. When a STA is capable of motion detection and is in motion, the In-Motion Report Interval and In-Motion number of frames per channel would apply.

11.21.5 Timing measurement procedure

Implementation of timing measurement is optional for a WNM STA. A STA in which dot11TimingMsmtActivated is true is defined as a STA that supports timing measurement.

A STA in which dot11TimingMsmtActivated is true shall set the Timing Measurement field of the Extended Capabilities element to 1.

A STA in which dot11TimingMsmtActivated is false shall set the Timing Measurement field of the Extended Capabilities element to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA that supports the timing measurement procedure may transmit a Timing Measurement Request frame to a peer STA to request it to initiate or to stop an ongoing timing measurement procedure, depending on the Trigger field in the request frame. See Figure 11-40 .

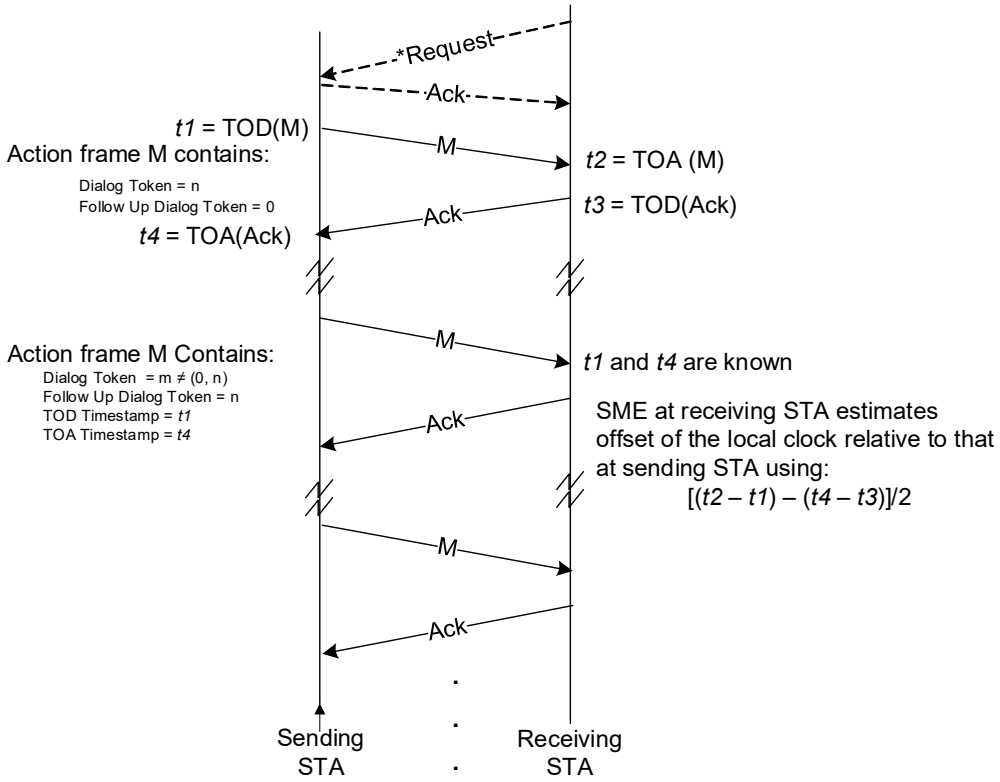

Figure 11-40—Timing measurement procedure

A STA that supports the timing measurement procedure may transmit Timing Measurement frames addressed to a peer STA that also supports the timing measurement procedure. One higher-layer protocol for synchronizing a local clock time between STAs using this feature is specified in IEEE Std 802.1AS.

For non-DMG STAs, both the Timing Measurement frame and the corresponding Ack frame shall be transmitted using a single transmit chain.

A sending STA transmits Timing Measurement frames in overlapping pairs. The first Timing Measurement frame of a pair contains a nonzero value in the Dialog Token field. The follow up Timing Measurement frame contains a Follow Up Dialog Token field set the value of the Dialog Token field in the first frame of the pair. With the first Timing Measurement frame, both STAs capture timestamps. The sending STA captures the time at which the Timing Measurement frame is transmitted (t1). The receiving STA captures the time at which the Timing Measurement frame arrives (t2) and the time at which the Ack frame response is transmitted (t3). The sending STA captures the time at which the Ack frame arrives (t4). In the follow up Timing Measurement frame, the sending STA transfers the timestamp values it captured (t1 and t4) to the receiving STA.

NOTE 1—A Timing Measurement frame can contain nonzero values in both the Dialog Token and Follow Up Dialog Token fields, meaning that the Action frame contains follow up information from a previous measurement, and new Timestamp values are captured to be sent in a future follow up Timing Measurement frame.

The offset of the clock at the receiving STA with respect to the clock at the sending STA is calculated using Equation (11-4) (assuming a symmetric wireless channel).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Clock offset at receiving STA relative to sending STA = $[(t2 - t1) - (t4 - t3)]/2$ (11-4)

NOTE 2—An example of state machines and other computations for synchronizing a local clock time between IEEE 802.11 STAs using the values of t1, t2, t3, and t4 provided by the Timing Measurement feature is found in Clause 12 of IEEE Std 802.1AS-2020.

The acknowledgment procedure for Timing Measurement frames is the same as that for other Management frames (see 10.3.2.11). If the Ack frame for a transmitted Timing Measurement frame is not received, the sending STA may retransmit the frame. The sending STA shall capture a new set of timestamps for the retransmitted frame and its Ack frame.

On receiving a Timing Measurement frame with a Dialog Token for which timestamps have previously been captured, the receiving STA shall discard previously captured timestamps and capture a new set of timestamps.

11.21.6 FTM procedure

11.21.6.1 General

The FTM procedure allows a STA to determine its range, relative range, and its direction to or from another STA using time of flight (TOF), time difference of arrival (TDOA), and phase measurement. In order for a STA to obtain its location, the STA may perform this procedure with multiple STAs whose locations are known.

An FTM session is an instance of an FTM procedure between an ISTA and an RSTA along with the associated scheduling and operational parameters (see 9.4.2.166 and 9.4.2.300). An FTM session is composed of a negotiation, measurement exchange, and termination.

An RSTA might be required to establish overlapping FTM sessions with a large number of ISTAs (e.g., an AP providing measurements to STAs at a mall or a store). On the other hand, an ISTA might have multiple ongoing FTM sessions on the same or different channels with different RSTAs, while being associated with an AP for the exchange of data or signaling.

Since some of the ISTA's activities may be nondeterministic and might have higher precedence than the FTM session (e.g., data transfer interaction with an associated AP), a conflict might prevent the ISTA from being available at the scheduled time window(s) for executing the ranging measurement exchange(s). The FTM procedure provides mechanisms as described in 11.21.6.1.1 and 11.21.6.1.2 to ensure that the ISTA is available to execute the ranging measurement exchange as scheduled.

11.21.6.1.1 EDCA based Ranging and TB ranging overview

To support the constraints of both the initiating and responding STAs, during negotiation the ISTA initially requests a preferred periodic time window allocation. The RSTA subsequently responds by accepting or overriding the allocation request based on its resource availability and capability.

The ISTA in Figure 11-41 establishes sessions with RSTA 1 and RSTA 2 on different channels. Since the ISTAs may not be able to be on channel (for instance, the ISTA is in the middle of some other activity) at the start of the negotiated time window (i.e., burst instance in the case of EDCA based ranging measurement exchange or availability window in the case of TB ranging measurement exchange (11.21.6.4.3) to execute the measurement exchange, within each instance of the negotiated time window, the ISTA indicates whether it is available to start the measurement exchange.

— In EDCA based ranging measurement exchange the ISTA indicates its availability to start the measurement exchange by sending an FTM Request frame with the Trigger field set to 1 during the corresponding burst instance.

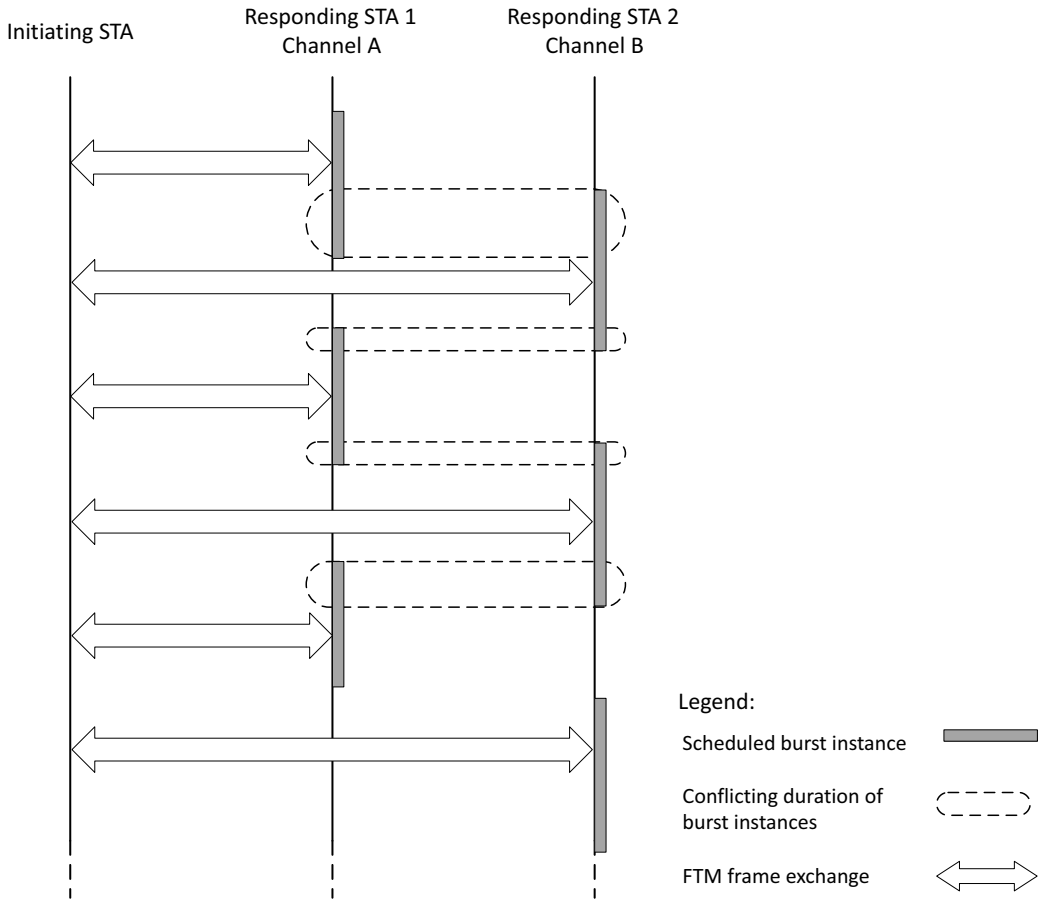

Figure 11-41—Concurrent FTM sessions

— In TB ranging measurement exchange (11.21.6.4.3), the ISTA indicates its availability to start the measurement exchange by responding to the Poll Ranging Trigger from the RSTA.

11.21.6.1.2 Non-TB ranging overview

Non-TB ranging measurement exchange is used by the ISTA to determine the measurement timing, based on its scheduling conflicts with other activities and the availability window parameters to identify the availability window instance, which is a time window referenced to the end of the previous measurement instance. During this measurement time window, the ISTA may come to the channel at any time and use contention based access to initiate a new measurement exchange. Because of conflict arising due to other activities, the ISTA does not start measurement at start of availability window while the RSTA waits for the start of measurement exchange. Figure 11-42 shows an example of concurrent non-TB ranging sessions. The dotted region indicates that the non-TB ranging measurement exchange does not always start at the beginning of the time window since the ISTA may have been active on another channel.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

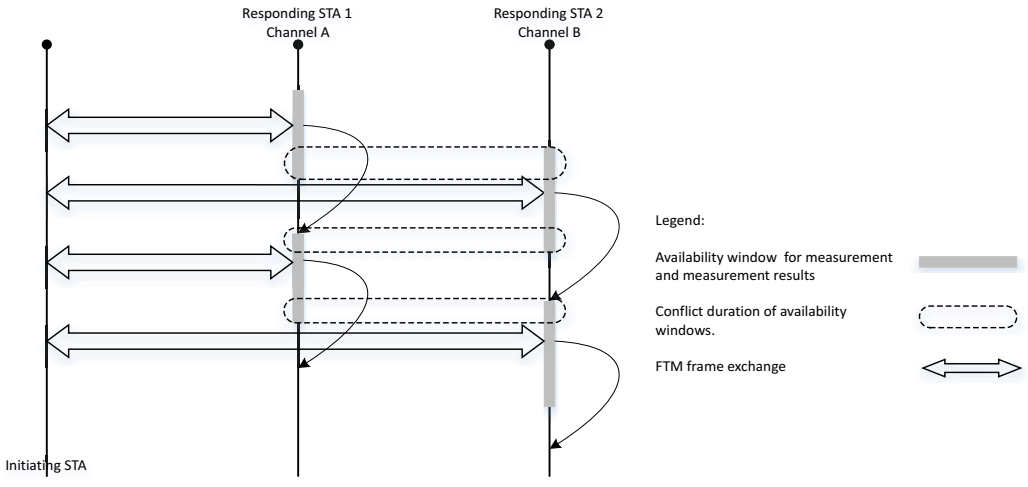

Figure 11-42—Non-TB ranging concurrent FTM sessions

The ISTA in Figure 11-42 , establishes sessions with RSTA 1 and RSTA 2 on different channels. Scheduling of each availability window instance is determined by the timing of the previous measurement instance with the corresponding RSTA. The constraints for an ISTA to initiate the non-TB ranging measurement exchange with each RSTA may be different. The RSTAs shall remain available within the entire availability window instance for the ISTA to initiate the non-TB ranging measurement exchange.

11.21.6.1.3 Passive TB ranging overview

Passive TB ranging is a variant of the TB ranging mode referred to in 11.21.6. In all aspects, except where explicitly stated differently, the passive TB ranging mode, its protocols, procedures, components, and definitions follow the rules for TB ranging.

The rules and procedures related to the use of management frame protection and secure HE-LTF in the TB ranging protocol does not apply to passive TB ranging.

NOTE 1—For example, the text in the following subclauses, and their subclauses, apply also to passive TB ranging:

- Subclause 11.21.6.1.1
- Subclause 11.21.6.3.3
- Subclause 11.21.6.4.3
- Subclause 11.21.6.5
- Subclause 11.21.6.5.1
- Subclause 11.21.6.6.2

NOTE 2—Below is a list of example exceptions for passive TB ranging where it does not follow the rules for TB ranging:

- The rules and procedures specific for the secure version of TB ranging does not apply to passive TB ranging.
- The RSTA uses the Ranging Trigger frame of subvariant Passive Sounding for its sounding trigger frames.
- The ISTAs use HE Ranging NDPs for their I2R NDPs.
- The ISTAs do not use the LMR frame for reporting of I2R LMR but instead use the ISTA Passive TB Ranging Measurement Report frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The RSTA sends the Primary and Secondary RSTA Broadcast Passive TB Ranging Measurement Report frames at the end of the measurement exchange.
— The number of spatial streams (NSTS) for passive TB ranging is limited to 4.
— When phase shift feedback is negotiated for passive TB ranging, both the RSTA and the ISTA measure and report PSTOAs, in addition to measuring and reporting TOAs.

The passive TB ranging mode consists of ranging exchanges between an RSTA and a set of ISTAs. These ranging exchanges and associated measurement reporting are set up such that an RSTA or ISTA can listen in to them and use the ranging exchanges and reported ranging measurements to estimate its differential distance to pairs formed by RSTAs and/or ISTAs. The listening STA, a passive STA (PSTA), is not itself an active transmitting participant in the ranging exchanges. That is, the PSTA can passively estimate its differential distances to the pairs of RSTAs and/or ISTAs. For a detailed description of how this differential distance can be calculated; see 11.21.6.4.8.3. It can then use these differential distances together with knowledge of the RSTA and ISTA locations to estimate its own location.

The RSTA centric scheduling for passive TB ranging operation operates as the RSTA centric scheduling for TB ranging operation referred to in 11.21.6.1.1. The availability window is here referred to as a passive TB ranging availability window. The passive TB ranging is scheduled by the RSTA in an availability window used for passive location.

In order to announce the scheduling and parameters of the availability window for passive TB ranging, the RSTA includes an RSTA Availability Window element (see 9.4.2.299) in its Beacon frame (see 9.3.3.2). Here, the Availability Window Broadcast Format subfield in the Header subfield in the RSTA Availability Information field in the RSTA Availability Window element is set to 1 to indicate that this is an RSTA Availability Window element that is used to signal availability windows for passive TB ranging.

The purpose of the announcement of the availability window for the passive TB ranging is to enable PSTAs to listen to the passive TB ranging exchanges that are occurring during the availability windows.

Consider passive TB ranging between a set of RSTAs and a set of ISTAs as depicted in Figure 11-43 . Here, three access points, AP1, AP2, and AP3, act as three passive TB ranging responder stations, RSTA1, RSTA2, and RSTA3. RSTA1 operates ranging exchanges in an availability window for passive TB ranging and is performing passive TB ranging exchanges with ISTA1, ISTA2, ISTA3, ISTA4, ISTA5, and ISTA6.

The PSTA is depicted, with the dashed arrows, as listening in to the passive TB ranging exchange between RSTA1 and ISTA4. Generalizing, the PSTA has the opportunity to receive the transmissions of all passive TB ranging exchanges occurring. The reception of each of these ranging exchange transmissions enables the PSTA to estimate its differential distance with respect to the RSTA–ISTA pair and use this information towards its location estimation.

In addition to the ranging exchanges between the ISTAs and RSTA1, the passive TB ranging protocol also allows the same ISTAs to measure time of arrivals of each other's ranging NDPs. An example of one such occurrence is depicted in Figure 11-43 in the form of the dotted double arrow between ISTA1 and ISTA2.

Furthermore, if one of the other APs in Figure 11-43 temporarily takes on the role of being an ISTA, it may also participate in RSTA1's passive TB ranging operation and perform passive TB ranging exchanges with RSTA1.

At other time intervals, RSTA2 and RSTA3 may operate their own passive TB ranging exchanges in their own availability windows. In each case, the ISTAs may perform passive TB ranging exchanges with RSTA2 or RSTA3.

Each of the access points operating as RSTA1, RSTA2, and RSTA3, announces the timing and bandwidth of its ranging availability window for passive TB ranging in its beacon in an RSTA Availability Window element.

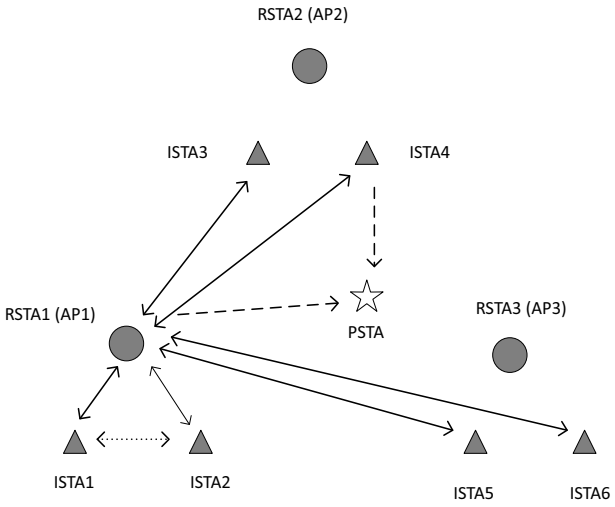

Figure 11-43—Example of passive TB ranging used for PSTA location—RSTA1 (AP1) operating passive TB ranging

By listening to the AP's beacons, the PSTA acquires this information for the different RSTA availability windows for passive TB ranging.

The PSTA listens to all of these ranging exchanges. Considering all ranging exchanges between all RSTAs and all ISTAs, the PSTA has the opportunity to overhear a large set of ranging exchanges between RSTAs and ISTAs in different locations, enabling the use of all of them towards its location estimation and also mitigating non-LOS issues between the ISTA(s)/RSTA involved in the ranging measurements.

The locations of the RSTA–ISTA or ISTA–ISTA pairs together with their differential distance with respect to the PSTA, generates a set of hyperbolic curves to which the PSTAs location is constrained. The intersection of these hyperbolic curves, or the best approximation to their intersection, is then an estimate of the PSTA's location.

11.21.6.2 FTM capabilities

Implementation of FTM is optional for a WNM STA. A STA in which dot11FineTimingMsmtRespActivated is true is defined as a STA that supports FTM as a responder. A STA in which dot11FineTimingMsmtInitActivated is true is defined as a STA that supports FTM as an initiator.

When dot11FineTimingMsmtRespActivated is true, dot11WirelessManagementImplemented shall be true. When dot11FineTimingMsmtInitActivated is true, dot11WirelessManagementImplemented shall be true.

A STA in which dot11FineTimingMsmtRespActivated is true shall set the FTM Responder field of the Extended Capabilities element to 1.

A STA in which dot11FineTimingMsmtInitActivated is true shall set the FTM Initiator field of the Extended Capabilities element to 1.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA in which dot11FineTimingMsmtRespActivated is false shall set the FTM Responder field of the Extended Capabilities element for non-DMG STA or the FTM Responder subfield of the DMG Fine Timing and Range Measurement Capability Information field of the DMG Capabilities element for DMG STA to 0.

A STA in which dot11FineTimingMsmtInitActivated is false shall set the FTM Initiator field of the Extended Capabilities element for non-DMG STA or the FTM Initiator subfield of the DMG Capabilities element for DMG STA to 0.

A STA in which dot11NonTriggerBasedRangingRespImplemented is true shall set the Non-TB Ranging Responder field of the Extended Capabilities element to 1. Otherwise, it shall set the Non-TB Ranging Responder field of the Extended Capabilities element to 0.

A STA in which dot11TriggerBasedRangingRespImplemented is true shall set the TB Ranging Responder field of the Extended Capabilities element to 1. Otherwise, it shall set the TB Ranging Responder field of the Extended Capabilities element to 0.

A STA in which dot11SecureLTFImplemented is true shall set the Secure HE-LTF Support field of the RSNXE to 1. Otherwise, it shall set the Secure HE-LTF Support field to 0.

A STA in which dot11RSTARequiresPMFActivated has the value Required (2) shall set the URNM-MFPR field of the RSNXE to 1. Otherwise, it shall set the URNM-MFPR field to 0.

A STA in which dot11RSTARequiresPMFActivated has the value Required-X20M (1) shall set the URNM-MFPR-X20 field of the RSNXE to 1. Otherwise, it shall set the URNM-MFPR-X20 field to 0.

A STA in which dot11DMGOptionImplemented is true and dot11FineTimingMsmtRespActivated is true shall set the FTM Responder subfield of the DMG Fine Timing and Range Measurement Capability Information field to 1.

A STA in which dot11DMGOptionImplemented is true and dot11FineTimingMsmtInitActivated is true shall set the FTM Initiator subfield of the DMG Fine Timing and Range Measurement Capability Information field to 1.

A STA in which dot11PassiveTBRangingResponderImplemented is true shall set the Passive TB Ranging Responder Measurement Support field of the Extended Capabilities element to 1. Otherwise, it shall set the Passive TB Ranging Responder Measurement Support field of the Extended Capabilities element to 0.

A STA in which dot11PassiveTBRangingInitiatorImplemented is true shall set the Passive TB Ranging Initiator Measurement Support field of the Extended Capabilities element to 1. Otherwise, it shall set the Passive TB Ranging Initiator Measurement Support field of the Extended Capabilities element to 0.

A STA shall set the Phase Shift Feedback Support field in the Extended Capabilities element to 1 if dot11PhaseShiftFeedbackImplemented is true and one of the following is true:

— dot11TriggerBasedRangingRespImplemented
— dot11NonTriggerBasedRangingRespImplemented
— dot11PassiveTBRangingInitiatorImplemented
— dot11PassiveTBRangingResponderImplemented

Otherwise it shall set the Phase Shift Feedback Support field in the Extended Capabilities element to 0.

A STA in which either dot11NonTriggerBasedRangingRespImplemented is true or dot11TriggerBasedRangingRespImplemented is true shall set the I2R LMR Feedback Policy field of the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Extended Capabilities element to 1 if dot11I2RLMRFeedbackPolicy is true. The STA shall set the I2R LMR Feedback Policy field of the Extended Capabilities element to 0 if dot11I2RLMRFeedbackPolicy is false.

An RSTA in which dot11PhaseShiftFeedbackImplemented is true shall set the Phase Shift TOA Feedback Support field in the Extended Capabilities element to 1 to indicate the RSTA's capability to support phase shift TOA feedback in the R2I LMR.

11.21.6.3 FTM procedure negotiation

11.21.6.3.1 General

In order to initiate an FTM procedure, a STA that supports the FTM procedure as an initiator (referred to as an ISTA) shall transmit an FTM Request frame. This frame is called the IFTMR frame. After transmission of this frame, the ISTA shall be ready to receive an FTM frame.

A STA that supports the FTM procedure as a responder (referred to as an RSTA) shall not transmit FTM frames addressed to a peer STA unless the RSTA has received an IFTMR frame from the peer STA.

The first FTM frame in the FTM session is called the initial FTM (IFTM) frame. The RSTA should transmit an IFTM frame within 10 ms in response to the IFTMR frame. This IFTM frame shall include either an FTM Parameters element or a Ranging Parameters element. The value of the Status Indication field indicates the outcome of the request.

NOTE 1—In an IFTM frame, the RSTA might indicate that the request for an FTM session is successful, even if the IFTM frame includes at least one of the following:

— A Measurement Report element that indicates an unknown LCI.
— A Measurement Report element that indicates an unknown civic location.

NOTE 2—If the ISTA and the RSTA are associated, the channel bandwidth used in the frame exchanges between the ISTA and the RSTA during the ranging measurement exchange is constrained by the rules listed in 10.6.5.8 and in 10.6.6.6.

If the ISTA and the RSTA are associated, a PTKSA is established as defined in 12.6.1.1.6, 12.7.6, 12.11.2, and 13.5. RSN capabilities MFPC and MFPR determine if the PTKSA between RSTA and ISTA is established or not.

If the ISTA and the RSTA are not associated the PTKSA is established using the preassociation security negotiation mechanism as defined in 12.13, and conditions to establish the context are defined below.

A secure FTM session is established when an ISTA and an RSTA establish a PTKSA and use it to exchange a Protected FTM Request Action frame, serving as the IFTMR frame, and the corresponding Protected FTM Action frame, serving as the IFTM frame, and the negotiation completes successfully; see 9.6.34. This applies to the following cases:

— A TB ranging measurement exchange.
— A non-TB ranging measurement exchange.
— An EDCA based ranging measurement exchange with a Format And Bandwidth field indicating DMG or EDMG format; see Table 9-325.

An ISTA shall not initiate FTM negotiation with a Protected FTM Request Action frame, that is, setup a secure FTM session, unless attempting to negotiate one of the cases listed above. A DMG or EDMG STA may use Protected Fine Timing frames in a DMG or EDMG EDCA based ranging session, respectively.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In the cases listed previously:

— If an RSTA has set the URNM-MFPR field in the RSNXE to 1, regardless of the setting in the URNM-MFPR-X20 field, an ISTA shall establish a PTKSA with that RSTA prior to initiating an FTM procedure negotiation with that RSTA.

— If the RSTA has set the URNM-MFPR-X20 field in the RSNXE to 1, an ISTA shall establish a PTKSA with that RSTA prior to initiating an FTM procedure negotiation with that RSTA unless the Format And Bandwidth subfield of the Ranging Parameters field (see 9.4.2.300) in the IFTMR indicates a 20 MHz Bandwidth.

— An RSTA shall reject an FTM request, if a PTKSA was required, and the ISTA has not successfully set up a PTKSA to allow protection of the FTMR frame, FTM and LMR frames exchanged between the RSTA and the ISTA.

The RSTA may accept the request in the cases not listed above.

11.21.6.3.2 Negotiation for EDCA based ranging measurement exchange

The IFTMR frame (see 11.21.6.3 and its retransmission(s) shall include an FTM Parameters element (see 9.4.2.166) with:

— the Trigger field set to 1, and

— a set of scheduling parameters that describe the ISTA's availability for measurement exchange, in the FTM Parameters field.

The FTM Parameters field shall not be present in any subsequent FTM Request frames.

In the case when an ISTA requests for a format equal to VHT and/or EDCA based HE and bandwidth equal to 160 MHz (80+80, 160 single RF LO, or 160 two separate RF LOs), the RSTA shall assign the same format and bandwidth as requested by the ISTA for 160 MHz bandwidth, otherwise it shall assign format and bandwidth less than or equal to 80 MHz. An ISTA performing an FTM procedure with an RSTA that is an AP shall support non-ASAP operation. An ISTA performing an FTM procedure with an RSTA that is not an AP shall support ASAP operation.

The ISTA shall indicate, in the Format And Bandwidth field, a format and bandwidth that it supports, and this may be different from the BSS bandwidth.

NOTE 1—The use of phase relations, per 19.3.11.11.4 and 21.3.7.5, between the 20 MHz parts in non-HT duplicate PPDUs that contain Ack frames transmitted by the ISTA is required to enable the RSTA to accurately determine the TOA of these frames, and is thus required for the ISTA to support FTM using Ack frames transmitted in non-HT duplicate PPDUs. Alternatively, an ISTA that supports transmission of Ack frames in VHT or HT PPDUs in response to FTM frames sent by the RSTA in VHT or HT PPDUs, respectively, is not required to support transmission of Ack frames in non-HT duplicate PPDUs in response to such FTM frames.

The ISTA shall indicate an EDCA based HE format in the Format And Bandwidth field sent to an RSTA if the STAs are operating in the 6 GHz band, at least one of the STAs does not support TB, or does not support non-TB ranging; otherwise the STA shall not indicate an EDCA based HE format in the Format And Bandwidth field.

A STA that supports TB or non-TB ranging is not required to support a Format And Bandwidth value of EDCA based HE.

For EDCA based ranging where the value of the corresponding Format And Bandwidth field value that indicates DMG or EDMG format, see Table 9-325, the ISTA shall indicate, in the Ranging Priority subfield of the FTM Parameters field of the FTM Parameters element in the IFTMR frame, its ranging priority as

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

described in Table 9-323. Otherwise, the Ranging Priority subfield of the FTM Parameters field of the FTM Parameters element is reserved.

When the request was successful:

- The RSTA shall indicate, in the Format And Bandwidth field, a format and bandwidth that it supports. The RSTA should indicate the same format and bandwidth in the Format And Bandwidth field as that requested by the ISTA, if the RSTA supports this. The RSTA shall not assign a value that indicates:
  - A bandwidth wider than requested
  - An EDCA based HE format if VHT, DMG, HT mixed, or non-HT format was requested
  - A VHT format if DMG, HT-mixed, or non-HT format was requested
  - An HT format if DMG or non-HT format was requested
  - A DMG format if EDCA based HE, VHT, HT-mixed, or non-HT format was requested
  - An EDCA based HE format only if EDCA based HE was requested, see 26.17.2, and the STA is operating in the 6 GHz band; otherwise the STA shall not indicate EDCA based HE format
  - A VHT (160 with two separate RF LOs) or a VHT (80+80) if a VHT (160 with single RF LO) was requested
  - A VHT (160 with single LO) or a VHT (80+80) if a VHT (160 with two separate RF LOs) was requested
  - A VHT (160 with single LO) or a VHT (160 with two separate RF LOs) if a VHT (80+80) was requested
  - An EDCA based HE (160 with two separate RF LOs) or an EDCA based HE (80+80) if an EDCA based HE (160 with single RF LO) was requested
  - An EDCA based HE (160 with single LO) or an EDCA based HE (80+80) if an EDCA based HE (160 with two separate RF LOs) was requested
  - An EDCA based HE (160 with single LO) or an EDCA based HE (160 with two separate RF LOs) if an EDCA based HE (80+80) was requested
  - An EDMG format if a DMG format was requested
  - An EDMG OFDM format if an EDMG SC format was requested
- An RSTA that is an AP shall support and select non-ASAP operation when so requested by an ISTA.
- An RSTA that is not an AP shall support and select ASAP operation when so requested by an ISTA.
- If the RSTA is ASAP capable, the RSTA's selection of ASAP should be the same as that requested by the ISTA.
- The RSTA's selection of the Min Delta FTM field value shall be greater than or equal to the value requested by the ISTA.
- The RSTA's selection of the Number of Bursts Exponent field value shall be 0 if the ISTA requested it to be 0.
- The RSTA's selection of the Burst Duration field value should be less than or equal to the one requested by the ISTA if the requested FTMs Per Burst field value is set to a value indicating no preference, subject the recommendations below and the RSTA's policy on the maximum and minimum Burst Duration field values.
- If the Number of Bursts Exponent field is set to 0 and the ASAP field is set to 1, the Burst Duration field value should be set to indicate the value BD_1, defined as follows:

$$BD_1 = ((N_{FTMPB} \times (K + 1)) - 1) \times T_{MDFTM} + T_{FTM} + \text{aSIFSTime} + T_{Ack}$$

where

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

N_{FTMPB} is the value of the FTMs Per Burst field
K is the maximum number of FTM frame retransmissions the RSTA might attempt
T_{MDFTM} is the duration indicated by the Min Delta FTM field of the FTM Parameters field of the IFTM frame (FTM_1)
T_{FTM} is the duration of the IFTM frame if the FTMs Per Burst field of the FTM Parameters field of FTM_1 is set to 1, and the duration of the non IFTM frame otherwise
T_{Ack} is the duration of the Ack frame expected as a response

— Otherwise, the Burst Duration field value should be set to indicate a value greater than or equal to the following value:

$$BD_1 + T_{FTMR} + \text{aSIFSTime} + T_{Ack} + T_{ACCESS\_FTM}$$

where
T_{FTMR} is the duration of an FTM Request frame without a Measurement Request element and without an FTM Parameters element
T_{ACCESS_FTM} is the estimated medium access time for the first FTM frame in a burst

— The RSTA's selection of the value of the FTMs Per Burst field should be the same as the one requested by the ISTA if the requested value of the Burst Duration field is set to a value indicating no preference, see Table 9-322, subject to the RSTA's policy on the maximum value of the FTMs Per Burst field.
— The RSTA's selection of Burst Period shall be greater than or equal the RSTA's selection of Burst Duration.
— When the Format And Bandwidth subfield indicates DMG or EDMG format, the RSTA's setting of the Ranging Priority is as defined in Table 9-324.

NOTE 2—Apart from the Status Indication, Value, ASAP, Number of Bursts Exponent, Min Delta FTM, and Burst Period fields, the other fields in the FTM Parameters element in the IFTM frame have no constraints.

When the RSTA cannot support the initiator's Min Delta FTM or Number of Bursts Exponent constraints, the RSTA shall set the Status Indication field to Request incapable and the FTM session ends. When the RSTA is unable to fulfill the request by the ISTA, the RSTA shall set the Status Indication field to Request failed and the FTM session ends.

11.21.6.3.3 Negotiation for TB and non-TB ranging measurement exchange

For TB and non-TB ranging Measurement exchange the IFTMR frame shall have:

— The Trigger field set to 1.
— A set of scheduling parameters in a Ranging Parameters element that describe the ISTA's availability for measurement exchange.

For TB and non-TB ranging measurement exchange, the IFTM frame shall include a Ranging Parameters element containing either the non-TB specific subelement, or the TB specific subelement.

The ISTA shall include one ISTA Availability Window element in the TB specific subelement in the IFTMR frame indicating its availability for TB ranging as well as the requested periodicity. The periodicity of the availability windows requested by the ISTA is expressed in units of 10 TUs in the Count subfield in the ISTA Availability Information field of the ISTA Availability Window element. The value of the Count subfield in the ISTA Availability Information field of the ISTA Availability Window element shall be a multiple of the Beacon Interval of the RSTA in units of 10 TUs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When the RSTA sets the Status Indication field in an IFTM frame to 1 (Success), it shall not include a Non-TB Specific subelement or TB-specific subelement, if the same subelement was not also included in the IFTMR frame by the ISTA.

When the RSTA includes a TB-specific subelement in an IFTM frame and the Status Indication field in the IFTM frame is equal to 1, then the RSTA shall include an RSTA Availability Window element in the IFTM frame. The RSTA Availability Information field in the RSTA Availability Window element shall contain exactly one Availability Window Information field. The Availability Window Information field represents the availability window assigned by the RSTA to the ISTA. The Availability Window Broadcast Format subfield in the Header subfield in the RSTA Availability Information field in this RSTA Availability Window element is set to 0.

When the RSTA includes a TB-specific subelement in an IFTM frame and the Status Indication field in the IFTM frame is equal to 1, the subelement contains an AID/RSID field assignment to the ISTA. The RSID and the AID are derived from the same ID number space and are non-conflicting.

When the RSTA includes a TB-specific subelement in an IFTM frame and the Status Indication field in the IFTM frame is equal to 1, the RSTA shall assign the value of the Max Session Exp field in the TB Ranging Specific subelement in the Ranging Parameters element in the initial FTM frame. The value of this field shall be larger than the assigned periodicity signaled in the Periodicity subfield in the Availability Window Information field in the TB ranging Specific subelement.

When a Ranging Parameters element is included in the IFTMR frame, the ISTA shall indicate the following parameters in the Ranging Parameters field:

- Maximum supported bandwidth in the Format And Bandwidth subfield.
- Maximum number of LTF repetitions it is capable of receiving in the preamble of the R2I NDP, in the Max R2I Repetition subfield.
- Maximum number of LTF repetitions it is capable of transmitting in the preamble of the I2R NDP, in the Max I2R Repetition subfield.
- Maximum number of space-time streams it is capable of receiving in the R2I NDP for bandwidths less than or equal to 80 MHz, in the Max R2I STS ≤ 80 MHz subfield.
- Maximum number of space-time streams it is capable of receiving in the R2I NDP for bandwidths greater than 80 MHz, in the Max R2I STS > 80 MHz subfield.
- Maximum number of space-time streams it is capable of transmitting in the I2R NDP for bandwidths less than or equal to 80 MHz, in the Max I2R STS ≤ 80 MHz subfield.
- Maximum number of space-time streams it is capable of transmitting in the I2R NDP for bandwidths greater than 80 MHz, in the Max I2R STS > 80 MHz subfield.
- Maximum number of LTFs in total it is capable of receiving, including all repetitions, in the R2I NDP, in the Max R2I LTF Total subfield.
- Maximum number of LTFs in total it is capable of transmitting, including all repetitions, in the I2R NDP, in the Max I2R LTF Total subfield.
- Immediate or delayed feedback capability in the I2R LMR by setting the Immediate I2R Feedback subfield to 1 or 0, respectively.

When based on the policy at the ISTA, the ISTA does not share measurement results with the RSTA, the ISTA shall set the I2R LMR Feedback subfield in the Ranging Parameters field, in the IFTMR frame, to 0. Otherwise the ISTA shall set the I2R LMR Feedback subfield to 1.

When the I2R LMR Feedback subfield in the IFTMR frame is equal to 0, and the I2R LMR Feedback Policy field in the Extended Capabilities element is set to 1 by the RSTA, then the RSTA shall not reject the request

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

because the I2R LMR Feedback subfield in the Ranging Parameters field was set to 0, and shall set the I2R LMR Feedback in the IFTM frame to 0.

When the I2R LMR Feedback subfield in the IFTMR frame is equal to 0, and the I2R LMR Feedback Policy field in the Extended Capabilities element is set to 0 by the RSTA, then the RSTA shall set the I2R LMR Feedback subfield to 1 to indicate it requests the ISTA to transmit the I2R LMR, or to 0 otherwise. In the former case, the ISTA may either proceed with measurement exchange; see 11.21.6.4.3 and 11.21.6.4.4, or terminate the FTM session (see 11.21.6.6).

When the I2R LMR Feedback subfield in the IFTMR frame is equal to 1, then the RSTA shall set the I2R LMR Feedback subfield to 1 to indicate it requests the ISTA to transmit the I2R LMR, or to 0 otherwise.

NOTE 1—The setting of the I2R LMR Feedback subfield to 1 in the Ranging Parameters field in the Ranging Parameters element contained in the IFTMR frame and IFTM frame is based on higher layer agreements.

NOTE 2—An RSTA that accepts a ranging request despite the ISTA having set the I2R LMR Feedback subfield in the Ranging Parameters field in the IFTMR frame to 0 enables use cases where the ISTA might share its location information at a higher layer.

When the ISTA sets the I2R AOA Requested subfield to 1 in the IFTMR frame, the RSTA may set the I2R AOA Requested subfield in the corresponding IFTM frame to 1 to confirm that the ISTA shall deliver the I2R AOA measurement result in any transmitted I2R LMR, and set to 0 otherwise.

When the ISTA sets the R2I AOA Requested subfield to 1 in the IFTMR frame, the RSTA may set R2I AOA Requested subfield in the corresponding IFTM frame to 1 to confirm that the RSTA shall deliver R2I AOA measurement results in the R2I LMR, and set to 0 otherwise.

When the ISTA indicated support to announce the TX power of its I2R NDPs by setting the I2R Tx Power field in the Non-TB specific subelement of the Ranging Parameters element in the IFTMR frame to 1, the RSTA may set the corresponding field in the IFTM frame to 1 to request the ISTA to announce the TX power of its I2R NDs, and 0 otherwise.

When the ISTA requested the RSTA to announce the TX power of its R2I NDPs by setting the R2I Tx Power field in the Non-TB Specific subelement to 1, the RSTA may set the corresponding field in the IFTM frame to 1. Otherwise, the RSTA shall set the R2I Tx Power field to 0.

For TB ranging and non-TB ranging, the ISTA shall indicate, in the Ranging Priority subfield of the Ranging Parameters field of the Ranging Parameters element in the IFTMR frame, its Ranging Priority according to Table 9-323.

For TB ranging, the RSTA shall indicate, in the Ranging Priority subfield of the Ranging Parameters field of the Ranging Parameters element in the IFTM frame, whether it accommodates the ranging priority request transmitted by the ISTA according to Table 9-324.

When the negotiation is successful for TB ranging and non-TB ranging, the corresponding IFTM frame from the RSTA shall include a Ranging Parameters element with the parameters that define the negotiated range measurement session. The RSTA shall indicate the following parameters in the Ranging Parameters field:

a) In the Format And Bandwidth subfield, it assigns the maximum allowed bandwidth used during measurement exchanges (referred to as RSTA Assigned Max Bandwidth). This value shall not be greater than the value in the corresponding IFTMR frame.
b) In the Max R2I Repetition subfield, it assigns the maximum number of HE-LTF repetitions in the preamble of the R2I NDP for this session (referred to as RSTA Assigned R2I Rep). This value shall not be greater than the value in the corresponding IFTMR frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

c) In the Max I2R Repetition subfield, it assigns the maximum number of HE-LTF repetitions in the preamble of the I2R NDP for this session (referred to as RSTA Assigned I2R Rep). This value shall not be greater than the value in the corresponding IFTMR frame.

d) In the Max R2I STS ≤ 80 MHz subfield, either the maximum number of space-time streams it is capable of transmitting in the R2I NDP for bandwidths less than or equal to 80 MHz, or the value in the corresponding IFTMR frame, whichever is smaller (referred to as RSTA Assigned R2I STS ≤ 80 MHz).

e) In the Max R2I STS > 80 MHz subfield, either the maximum number of space-time streams it is capable of transmitting in the R2I NDP for bandwidths greater than 80 MHz, or the value in the corresponding IFTMR frame (referred to as RSTA Assigned R2I STS > 80 MHz).

f) In the Max I2R STS ≤ 80 MHz subfield, either the maximum number of space-time streams it is capable of receiving in the I2R NDP for bandwidths less than or equal to 80 MHz, or the value in the corresponding IFTMR frame, whichever is smaller (referred to as RSTA Assigned I2R STS ≤ 80 MHz).

g) In the Max I2R STS > 80 MHz subfield, either the maximum number of space-time streams it is capable of receiving in the I2R NDP for bandwidths greater than 80 MHz, or the value in the corresponding IFTMR frame, whichever is smaller (referred to as RSTA Assigned I2R STS > 80 MHz).

h) In the Max R2I LTF Total subfield, either the maximum number of LTFs in total it is capable of transmitting to this ISTA, including HE-LTF repetitions, in the R2I NDP, or the value in the corresponding IFTMR frame, whichever is smaller (referred to as RSTA Assigned R2I LTF Total).

i) In the Max I2R LTF Total subfield, either the maximum number of LTFs in total it is capable of receiving, including HE-LTF repetitions, in the I2R NDP, or the value in the corresponding IFTMR frame, whichever is smaller (referred to as RSTA Assigned I2R LTF Total).

j) Immediate or delayed feedback in the R2I LMR by setting the Immediate R2I Feedback subfield to 1 or 0, respectively.

An ISTA and an RSTA may negotiate a phase shift feedback mode of the non-TB ranging and TB ranging measurement exchange (11.21.6.4.3), for either the R2I LMR and/or I2R LMR. In this case, instead of the TOA t2 of the I2R NDP, the R2I LMR carries the phase shift tp2 of I2R NDP and instead of the TOA t4 of the R2I NDP, the I2R LMR carries phase shift tp4 of R2I NDP. The ISTA and RSTA can use Equation (11-9) and Equation (11-10) to derive the RTT.

NOTE 3—tp2 and tp4 are reported in the same units of time (not angle) as the TOA; see 9.6.7.49 (LMR frame format).

If an RSTA has set the Phase Shift TOA Feedback Support field to 1 in the Extended Capabilities element, then to request phase shift TOA feedback in the R2I LMR, an ISTA shall set the R2I TOA Type subfield in the Ranging Parameter field in an IFTMR frame to 1. To assign phase shift TOA feedback in the R2I LMR the RSTA shall set the R2I TOA subfield in the Ranging Parameter field in an IFTM frame to 1, otherwise it shall set it to 0. If the RSTA sets the R2I TOA Type subfield in the Ranging Parameter field in an IFTM frame to 1, the RSTA shall report the phase shift TOA feedback (tp2 of the I2R NDP) in the R2I LMR.

An ISTA that has set the I2R LMR feedback subfield in the Ranging Parameters field in an IFTMR frame to 1, shall set the I2R TOA Type subfield to 1 to indicate that it supports phase shift TOA feedback in the I2R LMR, and set it to 0 otherwise. When the ISTA indicates that it does not support phase shift TOA feedback in the I2R LMR, then the RSTA shall set the I2R Type subfield to 0 in the IFTM frame. When the ISTA indicates support for phase shift TOA feedback in the I2R LMR, the RSTA shall set the I2R TOA Type subfield in the Ranging Parameters field of an IFTM frame to 1 to assign phase shift TOA feedback in the I2R LMR, otherwise it shall set it to 0. If the RSTA sets the I2R TOA Type subfield in the Ranging Parameters field of an IFTM frame to 1, the ISTA shall report phase shift TOA feedback (tp4 of the R2I NDP) in the I2R LMR.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An RSTA shall reject a request for TB ranging from an ISTA if the RSTA cannot assign the ISTA to an availability window that overlaps with a 10 TU interval in which the ISTA is available (as signaled by the ISTA Availability Window element in the IFTMR frame).

When an RSTA sets the Status Indication field in an IFTM frame to 1 (Successful), it shall include an FTM Synchronization Information element in this IFTM frame.

When the RSTA includes a TB-specific subelement in an IFTM frame and the Status Indication field in the IFTM frame is equal to 2 (Request incapable) or 3 (Request failed), then the RSTA may include an RSTA Availability Window element in the IFTM frame. The RSTA Availability Information field in the RSTA Availability Window element shall contain one or more Availability Window Information fields. Each Availability Window Information field represents an availability window that the RSTA can assign to that ISTA if requested by the ISTA in future. The passive TB ranging availability window bit in this Availability Window Information subfield is set to 0.

When Management Frame Protection is negotiated for TB and non-TB ranging, a STA shall:

— Use Protected Fine Timing Action frames for FTMR frames, FTM frames, and LMR frames for ranging negotiation and measurement
— Discard unprotected variants of these frames upon reception

An RSTA shall reject a request, unless the request is for passive TB ranging, if it has set the URNM-MFPR field of the RSNXE to 1, and the ISTA has not successfully set up a PTKSA to protect IFTMR, IFTM, and LMR frames exchanged between the RSTA and the ISTA.

Upon reception of an IFTMR frame with the Format And Bandwidth subfield set to a value of 3, 4, or 5 representing the ISTA's support for one of the 160 MHz BW options, the RSTA shall respond with the same requested value in the Format And Bandwidth subfield in the IFTM frame, if it supports the requested 160 MHz BW option, otherwise respond with a value less than 3.

11.21.6.3.4 Negotiation for secure HE-LTF in the TB and non-TB ranging measurement exchange

An ISTA and an RSTA may activate a secure HE-LTF measurement exchange for non-TB ranging or TB ranging that uses randomized LTF sequences in the I2R NDPs and R2I NDPs, refer to 11.21.6.4.5.

An RSTA in which dot11SecureLTFImplemented is true shall set the Secure HE-LTF Support field in the RSNXE to 1. An ISTA in which dot11SecureLTFImplemented is true shall include the Secure HE-LTF subelement in the Ranging Parameters element in an IFTMR frame.

When an RSTA has set the Secure HE-LTF Support field to 1 in the RSNXE, then to request a secure HE-LTF measurement exchange mode with the RSTA, an ISTA with dot11SecureLTFImplemented equal to true shall include the Secure HE-LTF subelement in the Ranging Parameters element in the IFTMR frame and set the value of the Secure HE-LTF Required field in the Secure HE-LTF subelement to 1.

When an ISTA has included the Secure HE-LTF subelement in the Ranging Parameters element in its IFTMR frame and set the value of the Secure HE-LTF Required field to 1, then the RSTA that has set the value of the Status Indication field to 1 (i.e., Successful) shall include the Secure HE-LTF subelement in the Ranging Parameter element in its IFTM frame and set the value of the Secure HE-LTF Required field to 1 to assign a secure HE-LTF measurement exchange mode with the ISTA.

When an ISTA has included the Secure HE-LTF subelement in the Ranging Parameters element in an IFTMR frame, then to assign a secure HE-LTF measurement exchange mode with the ISTA, an RSTA with

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

dot11SecureLTFImplemented equal to true shall include a Secure HE-LTF subelement in the Ranging Parameters element in an IFTM and set its Secure HE-LTF Required field to 1.

When an ISTA has included the Secure HE-LTF subelement in the Ranging Parameters element in its IFTMR frame and set the value of the Secure HE-LTF Required field to 1, the ISTA shall set the Max R2I Repetition and Max I2R Repetition subfields to a value greater than 0.

When an RSTA assigns a secure HE-LTF measurement exchange by including a Secure HE-LTF subelement in the Ranging Parameters element in its IFTM frame and setting the Secure HE-LTF Required subfield to 1, the RSTA shall set the *RSTA Assigned R2I Rep* to the Max R2I Repetition subfield value in the IFTMR frame which shall be greater than 0, and the RSTA shall set *RSTA Assigned I2R Rep* to a value greater than 0 and less than or equal to the Max I2R Repetition subfield value in the IFTMR frame, where the *RSTA Assigned R2I Rep* and *RSTA Assigned I2R Rep* specify the number of HE-LTF repetitions in the preamble of the R2I and I2R NDP for this session, respectively.

When an ISTA has included the Secure HE-LTF subelement in the Ranging Parameters element in the IFTMR frame, it shall indicate to the RSTA a request to use the optional frequency domain Tx window in the R2I NDPs by setting the R2I Tx Window field to 1, otherwise shall set it to 0; and indicate its support of the optional frequency domain Tx window in the I2R NDPs by setting the I2R Tx Window field to 1, otherwise shall set it to 0.

When an RSTA has assigned a secure HE-LTF measurement exchange mode, by including a Secure HE-LTF subelement in the Ranging Parameters element in the IFTM frame, and setting its Secure HE-LTF Required field to 1, the RSTA shall also include a Secure HE-LTF Parameters element in the IFTM frame that contains the values of the Validation SAC and Secure LTF Counter subfields.

The secure HE-LTF negotiation supports negotiation of the secure HE-LTF protocol version; see Table 9-415, which allows an RSTA and ISTA to negotiate the highest mutually supported secure HE-LTF protocol version. The secure HE-LTF protocol version is indicated in the Protocol Version field within the Secure HE-LTF subelement. If an RSTA includes a Secure HE-LTF element in the IFTM frame, it shall set the Protocol Version subfield to either the same or a lower value than the ISTA's Secure Protocol Version sent in the IFTMR frame with the Status Indication subfield equal to 1 (i.e., Success), or a higher value than the ISTA's Secure Protocol Version with the Status Indication subfield equal to 2 (i.e., 'Request Incapable. Do not send same request again'). Upon receiving an IFTM frame with Status Indication subfield set to 1 (i.e., successful) that includes a Secure HE-LTF subelement, the ISTA shall either proceed with the RSTA's Protocol Version assignment, or if it does not meet its required security level, shall terminate by transmitting an FTMR frame with trigger field set to 0.

NOTE—The secure HE-LTF protocol version negotiation provides user, or system, feedback about the protocol version used, as reported by the MLME. If the negotiation results in termination, user feedback can also be given about the mismatch of versions, helping them understand why it has failed, and what they need to do to address the problem.

When an RSTA has initiated a secure measurement exchange, by including a Secure HE-LTF subelement in the Ranging Parameters element in the IFTM frame, and setting the Secure HE-LTF Required field to 1, then it shall indicate to the ISTA whether the I2R and R2I NDPs will use the optional frequency domain Tx window by setting the I2R Tx Window and R2I Tx Window fields in the Secure HE-LTF subelement respectively; see Figure 9-1050 .

— If the ISTA had set the I2R Tx Window field to value 1 in the IFTMR frame and the RSTA sets the corresponding I2R Tx Window field in the IFTM frame to value 1, the ISTA shall use the optional frequency domain Tx Window in the I2R NDPs.
— If the ISTA had set the R2I Tx Window field to value 1 in the IFTMR frame and the RSTA sets the corresponding R2I Tx Window field to value 1 in the IFTM frame, the RSTA shall use the optional frequency domain Tx window in the R2I NDPs.

The Measurement SAC field in the Secure HE-LTF Parameters element is reserved in any IFTM frame.

When dot11SecureLTFImplemented is true, prior to generating the new secure LTF counter for a given PTKSA, the RSTA initializes a monotonically increasing 48-bit counter Secure-LTF-Counter to 0. The RSTA also derives a Secure-LTF-Key-Seed as follows:

Secure-LTF-Key-Seed = HMAC-Hash(KDK, “Secure LTF key seed”)

Where the KDK is derived as part of PTKSA establishment, Hash is the hash determined by the AKM and used to derive the PTK. If the Extended Key ID for Individually Addressed Frames subfield of the RSN Capabilities field is 1 for both the Authenticator and the Supplicant, there may be multiple KDKs each identified by a different Key ID (0 or 1). In such a case, the KDK chosen to derive the Secure-LTF-Key-Seed shall be the most recent.

Similarly, when dot11SecureLTFImplemented is true, an ISTA also derives the same Secure-LTF-Key-Seed prior to initiating a secure FTM negotiation.

For each secure FTM negotiation, prior to transmission of IFTM, and for each measurement within an FTM session, an RSTA shall increment the Secure-LTF-Counter by 1. The Secure-LTF-Counter is included in the Secure HE-LTF Parameters element conveyed to the ISTA. An ISTA determines the Secure-LTF-Counter to use for a measurement using the Secure LTF Counter and Validation SAC received from the RSTA in the most recent protected IFTM or LMR frame. The Secure-LTF-Counter shall be reset when a new KDK is derived as part of a new PTK derivation and it shall continue, and not be reset, for each secure FTM negotiation using a given KDK.

11.21.6.3.5 Capability negotiation for EDCA based ranging with the Format And Bandwidth field set to value in range 31–43

A STA that supports first Path Beamforming Training shall set the First Path Beamforming Training Supported field of the Beamforming Capability subelement in the EDMG Capabilities element to 1. Otherwise it shall set the First Path Beamforming Training Supported field to 0.

A STA that supports secure RTT measurement as described in 11.21.6.4.2.7 shall set the Secure RTT Support field in the RSNXE to 1. Otherwise, it shall set the Secure RTT Support field to 0. A STA shall not set the Secure RTT Support field in the RSNXE to 1 if it has not also set the First Path Beamforming Training Supported field of the Beamforming Capability subelement in the EDMG Capabilities element to 1.

A STA that supports EDMG SC Ranging shall set the EDMG SC Ranging Supported field of the Beamforming Capability subelement in the EDMG Capabilities element to 1. Otherwise it shall set the EDMG SC Ranging Supported field to 0.

A STA that supports EDMG OFDM Ranging shall set the EDMG OFDM Ranging Supported field of the Beamforming Capability subelement in the EDMG Capabilities element to 1. Otherwise, it shall set the EDMG OFDM Ranging Supported field to 0; see 11.21.6.3.6.

11.21.6.3.6 Negotiation for secure EDMG TRN in EDCA based ranging measurement

An ISTA may request a Secure RTT measurement by setting the Secure RTT Measurement subfield in the Measurement Parameters field in the initial Protected FTM Request frame. An ISTA shall not set the Secure RTT Measurement subfield to 1 in a request to an RSTA if the RSTA has not set the Secure RTT Support field in the RXSNE. An ISTA that sets the Secure RTT Measurement subfield to 1 shall generate a 32-octet random Secret Key and include it in the Secure Ranging Operation Parameters field; see Figure 9-1051 , in the initial Protected FTM Request frame. An RSTA that supports Secure RTT measurement shall acknowledge a request

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

for Secure RTT measurement by setting the Secure RTT Measurement subfield in the Measurement Parameters field in the initial Protected FTM frame.

11.21.6.3.7 Direction measurement negotiation for DMG STAs

A STA that supports inclusion of a TRN field in the transmitted FTM frame and the corresponding acknowledgment to facilitate angle of arrival measurements at the recipient shall set the AOA TX Capability subfield in the DMG Direction Measurement Capabilities field in the DMG Capabilities element to 1. Otherwise it shall set the AOA TX Capability subfield to 0.

A STA that supports angle of arrival estimation using the TRN field included in the received FTM frame or the corresponding acknowledgment shall set the AOA RX Capability subfield in the DMG Direction Measurement Capabilities field in the DMG Capabilities element to 1. Otherwise, it shall set the AOA RX Capability subfield to 0.

A STA that supports inclusion of direction setting specific TRN field(s) in the transmitted FTM frame and the corresponding acknowledgment to facilitate angle of departure estimation(s) at the recipient shall set the AOD TX Capability subfield in the DMG Direction Measurement Capabilities field in the DMG Capabilities element to 1. Otherwise, it shall set the AOD TX Capability subfield to 0.

A STA that supports angle of departure estimation using the TRN field(s) included in the received FTM frame or the corresponding acknowledgment shall set the AOD RX Capability subfield in the DMG Direction Measurement Capabilities field in the DMG Capabilities element to 1. Otherwise, it shall set the AOD RX Capability subfield to 0.

A pair of ISTA and RSTA are defined to be mutually direction measurement capable if both the ISTA and the RSTA indicated support for DMG direction measurement by including the DMG Direction Measurement Capabilities field in the DMG Capabilities element, and by the ISTA setting at least one of the first four subfields (AOA TX Capability, AOA RX Capability, AOD TX Capability, AOD RX Capability) of this field to 1 and the RSTA setting one the corresponding subfields (AOA RX Capability, AOA TX Capability, AOD RX Capability, AOD TX Capability) of this field to 1. A DMG ISTA may request that FTM exchanges will include direction measurement if the ISTA and RSTA are mutually direction measurement capable.

A DMG ISTA may request initiator AOA measurement, responder AOA measurement, initiator AOD measurement, and responder AOD measurement, by including a DMG Direction Measurement Parameters subelement in the FTM Parameters element transmitted in the FTMR frame. Valid combinations of AOA and AOD requests and the corresponding required capabilities are shown in Table 11-16. The L-RX field in the DMG Direction Measurement Specific Parameters subelement shall be set to the number of TRN units the ISTA needs for AOA estimation in the case where R2I AOA was requested, otherwise it shall be set to 0.

The RSTA should respond within 10 ms from the IFTMR frame with an IFTM frame with an FTM Parameters element with a DMG Direction Measurement Parameters subelement. The requested AOA/AOD I2R/R2I parameters in the IFTM frame shall be set to the same value as those requested in the IFTMR frame. The L-RX field shall be set to the number of TRN units the RSTA needs for AOA estimation in the case where I2R AOA was requested. The RSTA sets the Direction Measurement Density field.

The AOA and AOD parameters requested in the IFTMR frame shall be compatible with the corresponding AOA/AOD TX/RX capabilities as shown in Table 11-16.

11.21.6.3.8 LOS assessment negotiation for EDMG STAs

An EDMG STA that supports LOS assessment by transmitting a LOS Assessment FTM PPDU shall set the dot11LOSAssessmentTXImplemented to true and shall set it to false otherwise.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table 11-16—Valid combinations of direction measurements requests and the required capabilities at the initiator and responder

Requested parameters				Required initiator capabilities				Required responder capabilities			
R2I AOA	I2R AOD	I2R AOA	R2I AOD	AOA RX	AOA TX	AOD RX	AOD TX	AOA RX	AOA TX	AOD RX	AOD TX
Y				Y					Y		
	Y						Y			Y	
		Y			Y			Y			
			Y			Y					Y
Y	Y			Y			Y		Y	Y	
		Y	Y		Y	Y		Y			Y
Y		Y		Y	Y			Y	Y		
	Y		Y			Y	Y			Y	Y

An EDMG STA that in the role of RSTA supports LOS assessment by switching polarization while receiving a LOS Assessment Ack PPDU and responds with Channel Measurement feedback shall set the dot11LOSAssessmentRXImplemented to true and shall set it to false otherwise.

An EDMG STA for which the dot11LOSAssessmentTXImplemented is true shall set to 1 the LOS Assessment TX Capability subfield in the DMG Direction Measurement Capabilities field.

An EDMG STA for which the dot11LOSAssessmentRXImplemented is true shall set to 1 the LOS Assessment RX capability and the LOS Assessment TX Capability subfields in the DMG Direction Measurement Capabilities field.

An EDMG STA in ISTA role for which the dot11LOSAssessmentTXImplemented is true may establish an FTM session that contains LOS assessment exchanges with another EDMG STA that will take the RSTA role if that STA's LOS Assessment RX capability subfields in the DMG Direction Measurement Capabilities field is set to 1.

The ISTA requests the FTM session by setting the LOS Assessment field to 1 in a DMG Direction Measurement Parameters subelement in the IFTMR frame. The responding RSTA shall set to 1 the LOS Assessment field in the DMG Direction Measurement Parameters element in the IFTM frame.

11.21.6.3.9 Passive TB ranging measurement negotiation

The passive TB ranging measurement negotiation follows the rules and procedures for the TB ranging measurement negotiation detailed in 11.21.6.3.3, unless explicitly stated otherwise.

A STA in which dot11PassiveTBRangingResponderImplemented is true shall set the Passive TB Ranging Responder Measurement Support field in the Extended Capabilities element to 1.

When an RSTA has set the Passive TB Ranging Responder Measurement Support field to 1 in the Extended Capabilities element it transmits, an ISTA with dot11PassiveTBRangingInitiatorImplemented equal to true may set the Passive TB Ranging field in the TB specific subelement in an IFTMR frame to 1 to request a passive TB ranging measurement session between the ISTA and the RSTA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When requesting, or responding to a request for, passive TB ranging, the I2R LMR Feedback subfield in the Ranging Parameters field of the Ranging Parameters element in the IFTMR and IFTM frames, respectively, is reserved.

NOTE—This is because in passive TB ranging, the transmission of the ISTA Passive TB Ranging Measurement Report frame is mandatory; see 11.21.6.4.8.4.

To assign an ISTA passive TB ranging session, the RSTA shall respond with the Passive TB Ranging subfield in the Ranging Parameters field set to 1 in the corresponding IFTM frame.

When an ISTA sets the Passive TB Ranging field in the TB specific subelement in an IFTMR frame to 1, the ISTA shall not include the Secure HE-LTF subelement in the Ranging Parameters element in an IFTMR frame.

The negotiation of phase shift feedback in passive TB ranging follows the same behavior as for TB ranging.

If the ISTA sets the Passive TB Ranging field to 1, it shall include an LCI report in the FTM Request frame.

11.21.6.4 Measurement exchange

11.21.6.4.1 FTM exchange overview

FTM has three basic ranging mechanisms:

— EDCA based ranging described in 11.21.6.4.2
— TB ranging described in 11.21.6.4.3 and 11.21.6.4.8
— Non-TB ranging described in 11.21.6.4.4

The frequency of the clock for the FTM timestamps shall be derived from the same reference oscillator as the transmit center frequency and the symbol clock frequency.

NOTE—The transmit center frequency and symbol clock frequency are derived from the same reference oscillator, as per the specifications for the different PHYs.

11.21.6.4.2 EDCA based ranging measurement exchange

11.21.6.4.2.1 Common behavior for EDCA based ranging measurement exchange

The time windows during which TOD measurement for the transmission of the FTM frame and the TOA measurement on the receipt of the acknowledgment corresponding to the transmitted FTM frame are performed are known as burst instances. FTM frames over which TOD and TOA measurements are performed shall not be sent outside burst instances. The timing of the burst instances is defined by the following parameters:

— Partial TSF Timer: The partial TSF timer, as defined in 9.4.2.166, at the beginning of the first burst instance.
— Burst Duration: The duration of each burst instance starting at the boundary of a burst period.
— Burst Period: The interval from the beginning of one burst instance to the beginning of the following burst instance.

The ISTA shall transmit an FTMR frame without a Measurement Request element, without an FTM Parameters element and with the Trigger field set to 1 as soon as it is available on channel during a burst instance. This indicates to the RSTA its availability for the remainder of the burst instance. In response, the RSTA shall transmit an Ack frame and should transmit FTMs Per Burst FTM frames before the end of the burst instance. In addition, the ISTA shall be ready to receive an FTM frame. The first FTM frame and its retransmissions in the burst instance from the RSTA shall include an FTM Synchronization Information

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

element in the FTM Synchronization Information field. The TSF Sync Info field in the FTM Synchronization Information element contained in the FTM frame might be used by the ISTA to synchronize its TSF with the RSTA's in order to determine the start of subsequent burst instances. Subsequent FTM frames within the burst instance shall not include an FTM Parameters element and shall not include an FTM Synchronization Information field (for additional constraints on the FTM frame see 11.21.6.7). Consecutive FTM frames to a given peer STA shall be spaced at least Min Delta FTM apart. Within a burst instance the ISTA shall perform FTM on each FTM frame addressed to it, except the last FTM frame. The ISTA may perform FTM on the last FTM frame in a burst instance.

NOTE 1—If the ISTA successfully transmits an FTM Request frame with the Trigger field set to 1 late in a burst duration, fewer than the negotiated per burst TOF measurements (i.e., the value of the FTM Per Burst field) might be completed within this burst duration instance.

NOTE 2—If an FTM frame, except for the IFTM frame in the ASAP=0 case, is sent outside a burst instance, it might not be acknowledged.

The first burst instance shall start at the value indicated by the Partial TSF Timer subfield in the IFTM frame, regardless of the ASAP field's value. When ASAP is 1 by the RSTA, the Partial TSF Timer subfield value shall be set to a value less than 10 ms from the reception of the most recent IFTMR frame.

The scheduling parameters of an FTM session are illustrated in Figure 11-44 .

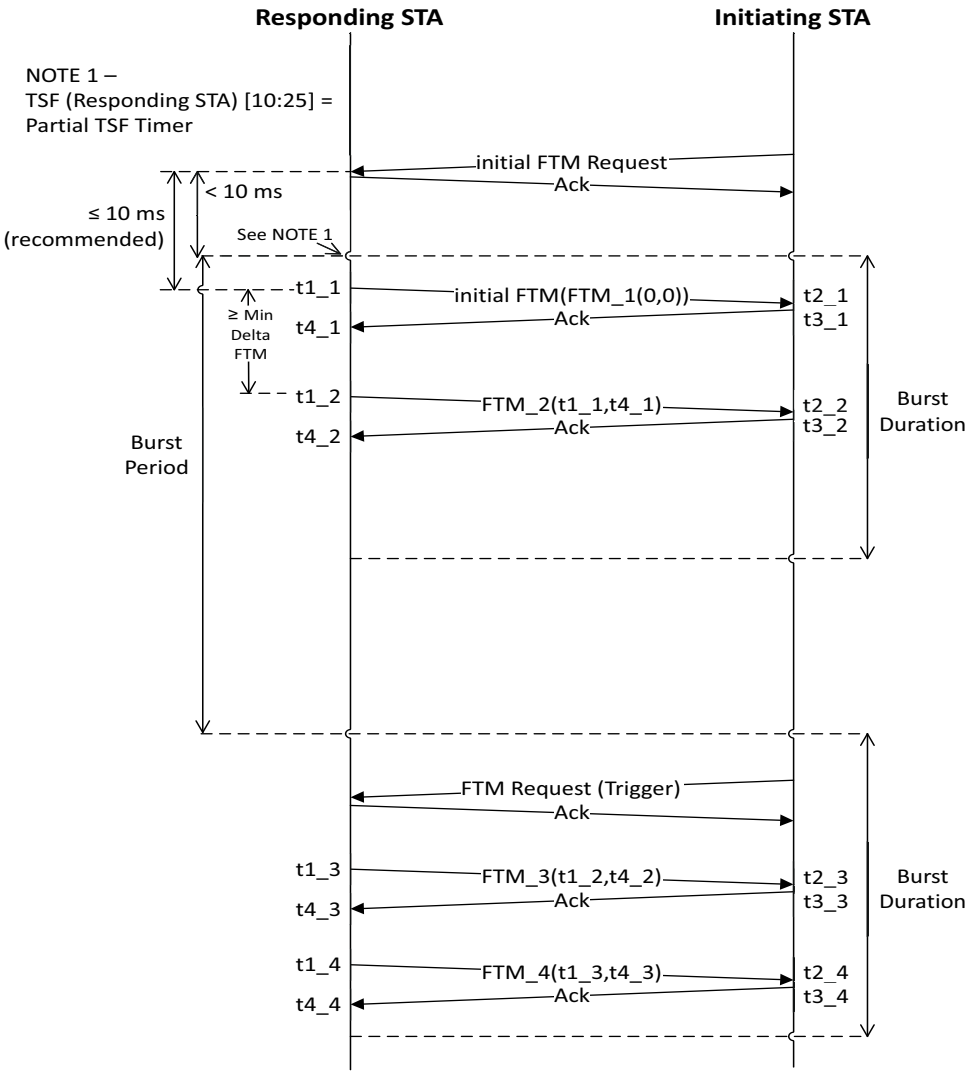

Figure 11-44—Example negotiation and measurement frame exchange, ASAP=0, and FTMs Per Burst = 2

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The ISTA can request the RSTA to start the burst instances “as soon as possible” by setting the ASAP subfield to 1. The scheduling in this case is illustrated in Figure 11-45 .

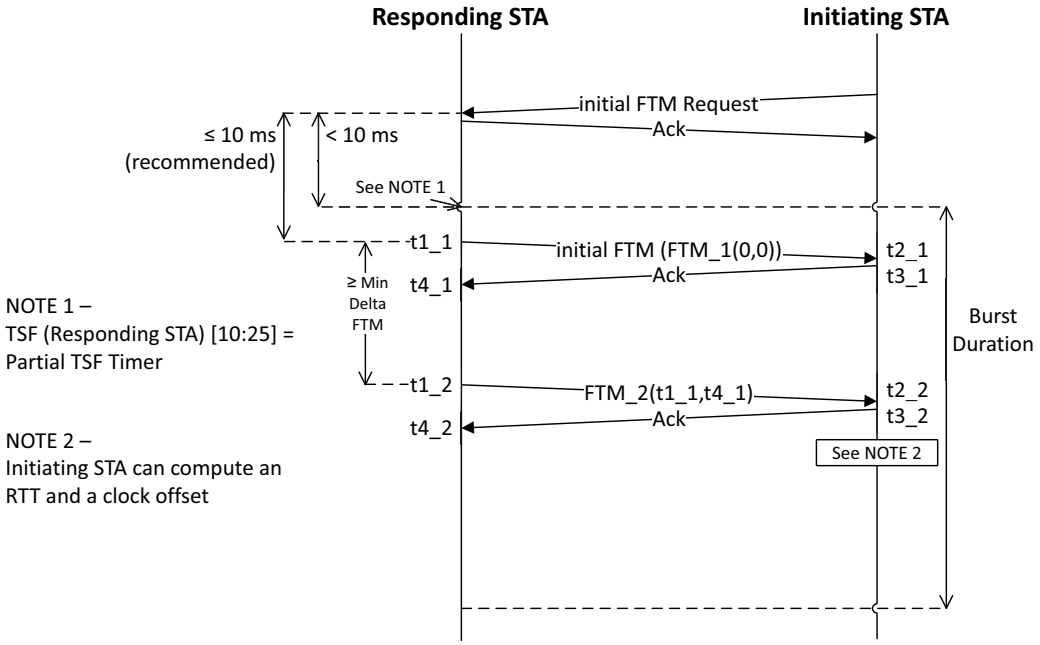

Figure 11-45—Example negotiation and measurement frame exchange, ASAP=1, and FTMs Per Burst = 2

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The ISTA may also request a single burst of FTMs to be taken as soon as possible, in which case it sets the Number of Bursts Exponent subfield to 0 and the ASAP subfield to 1. This is illustrated in Figure 11-46 .

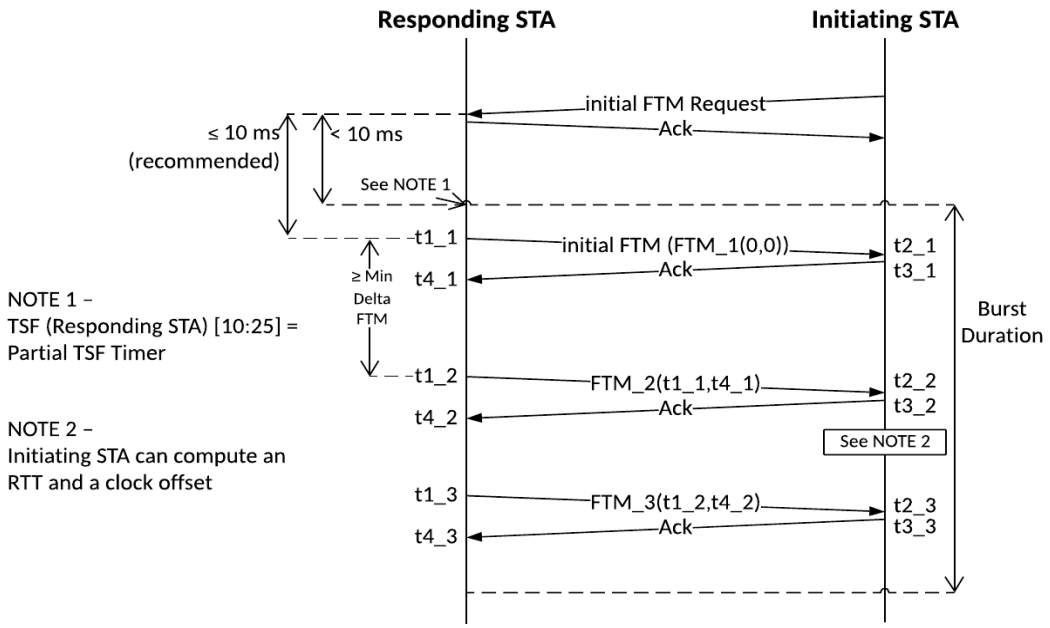

Figure 11-46—Example negotiation and measurement frame exchange for a single burst instance, ASAP=1, and FTMs Per Burst = 3

For non-DMG STAs, both the FTM frame and the corresponding Ack frame shall be transmitted using a single transmit chain.

The RSTA shall not transmit FTM frames using Clause 15 or Clause 16 formats, MCS 32 format, or HT-greenfield format.

The RSTA should transmit FTM frames with the format and bandwidth it indicated in the IFTM frame.

For the FTM frames transmitted during the FTM session:

- The RSTA shall not use a bandwidth wider than it indicated in the IFTM frame.
- The RSTA shall not use an HE format if it indicated VHT, HT-mixed, or non-HT format in the IFTM frame.
- The RSTA shall not use a VHT format if it indicated HT-mixed or non-HT format in the IFTM frame.
- The RSTA shall not use an HT format if it indicated non-HT format in the IFTM frame.

The ASAP Capable subfield shall be set to 1 in the IFTM frame if a RSTA is ASAP-capable; otherwise it shall be set to 0.

A RSTA transmits FTM frames in overlapping pairs of consecutive frames. For example, in Figure 11-45 , FTM_1 and FTM_2, FTM_2 and FTM_3, and FTM_3 and FTM_4 are overlapping pairs of consecutive frames. The first FTM frame of a pair of consecutive FTM frames contains a nonzero value in the Dialog Token field. The follow up FTM frame contains a Follow Up Dialog Token field set to the value of the Dialog Token field in the first frame of the consecutive pair. Dialog Token field values of consecutive FTM frames

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

shall increment in steps of 1, except when the value wraps around to 1 or in the last FTM frame in an FTM session.

NOTE 3—An FTM frame can contain nonzero values in both the Dialog Token and Follow Up Dialog Token fields, meaning that the Action frame contains follow up information from a previous measurement, and new timestamp values are captured to be sent in a future follow up FTM frame.

With the first FTM frame, both STAs capture timestamps. The RSTA captures the time at which the FTM frame is transmitted (*t1*). The ISTA captures the time at which the FTM frame arrives (*t2*) and the time at which the Ack response is transmitted (*t3*). The RSTA captures the time at which the Ack frame arrives (*t4*). In the follow up FTM frame, in the same or the subsequent burst, the RSTA transfers the timestamp values it captured (*t1* and *t4*) to the ISTA. In this follow up FTM frame, the timestamp values (*t1* and *t4*) shall be the measurement according to the RSTA's clock (i.e., without applying any frequency offset correction to the time bases).

For thetimestamp captures, *t1* and *t3* correspond to the point in time at which the start of the preamble for the transmitted FTM frame appears at the antenna connector during transmit (see Figure 11-47). An implementation may capture a timestamp during the transmit processing earlier or later than the point at which it actually occurs and offset the value to compensate for the time difference.

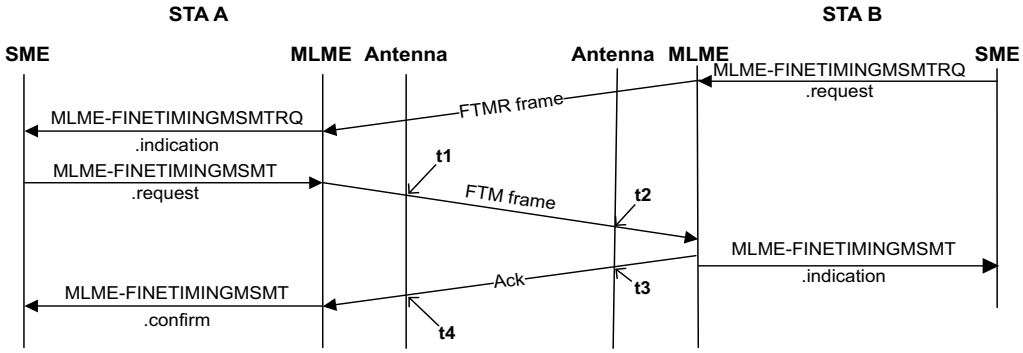

Figure 11-47—FTM primitives and timestamps capture for EDCA based ranging measurement exchange

Timestamp captures *t2* and *t4* correspond to the point in time at which the start of the preamble for the incoming FTM frame arrives at the receive antenna connector (see Figure 11-47). Because time is needed to detect the frame or the relevant LTF in the preamble and synchronize with its logical structure, an implementation determines when the start of the preamble or the relevant LTF in the preamble for the incoming frame arrived at the receive antenna connector by capturing a timestamp some time after it occurred and compensating for the delay by subtracting an offset from the captured value.

When the ASAP subfield is set to 0 by a RSTA, the Follow Up Dialog Token, TOD, TOA, TOD Error, and TOA Error fields in the FTM frame following the IFTM frame shall be reserved.

When the ASAP subfield is set to 1 by a RSTA, the timestamps for the IFTM frame shall be captured and sent in the following FTM frame. In the FTM frame following the IFTM frame, the TOD and TOA fields shall be set to the timestamps associated with the IFTM frame.

The round trip time (RTT) is defined by Equation (11-5).

$$RTT = [(t4' - t1') - (t3 - t2)] \quad (11\text{-}5)$$

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

where *t1*' and *t4*' are the time at which the FTM frame was transmitted and the time at which the Ack was received, respectively, as determined by the ISTA.

At the ISTA, the mechanism by which *t1*' and *t4*' are derived from the TOD and TOA fields is implementation dependent.

The FTM procedure can also be used to synchronize a local clock between STAs. One higher-layer protocol for synchronizing a local clock time between STAs is specified in IEEE Std 802.1AS.

The SME at the ISTA may estimate the offset of the local clock relative to that at the RSTA using clock offset as defined by Equation (11-6).

$$clock\ offset = [(t2 - t1') - (t4' - t3)]/2 \quad (11\text{-}6)$$

NOTE 4—The ISTA might track this clock offset over time to derive an estimate of the difference between the ISTA's time base and the RSTA's time base, and thereby improve the accuracy of its derivation of *t1*' and *t4*' from the TOD and TOA fields.

If the Ack frame for a transmitted FTM frame is not received, the RSTA shall not retry the frame. In order to send the frame again, the RSTA shall send an FTM frame with the same Action frame body as the FTM frame for which the Ack was not received, except for updating the Dialog Token if it was nonzero. The Sequence Number in the MAC header is also updated. This is called an *FTM retransmission*.

A RSTA that transmits an FTM frame with the ASAP subfield set to 0 shall set the Partial TSF Timer subfield to an offset value D_{TSF} from the partial value of the RSTA's TSF timer at the time of the transmission of the Ack to the last FTMR frame from the ISTA, subject to

$$D_{TSF} \geq K\_1 \times T_{MDFTM} + T_{FTM\_1} + \text{aSIFSTime} + T_{Ack} + T_{ACCESS\_FTM1}$$

where

K_1	is the maximum number of IFTM frame (FTM_1) retransmissions the RSTA might attempt
T_{MDFTM}	is the value of the Min Delta FTM subfield of the FTM Parameters field of FTM_1
T_{FTM_1}	is the duration of the FTM_1
T_{Ack}	is the duration of the Ack frame expected as a response
T_{ACCESS_FTM1}	is the estimated medium access time for FTM_1

NOTE 5—This Partial TSF Timer subfield ought to result in the FTMR frame not being transmitted before a successful transmission of FTM_1.

When neither an Ack to the IFTM frame nor an FTMR frame has been received by the RSTA, the RSTA shall not terminate the FTM session before the time indicated by the Partial TSF timer plus the Burst Duration.

The RSTA shall set the Follow Up Dialog Token field to 0 in the IFTM frame and its FTM retransmissions.

The RSTA shall set the Dialog Token field to 0 in the last FTM frame and its FTM retransmissions.

When a Secure FTM Session is established as described in 11.21.6.3.1, the FTM frames transmitted during the execution of Measurement Exchange shall be Protected Fine Timing Action frames; see 9.6.34.

11.21.6.4.2.2 DMG general measurement exchange

An EDMG ISTA and RSTA that have both indicated support for first path beam forming by setting to 1 the First Path Training Supported field in the Beamforming Capability subelement of the EDMG Capability element shall perform first path beamforming training as defined in 10.41.10.6 prior to any FTM exchange.

A DMG/EDMG ISTA/RSTA performs an FTM exchange that does not require AOA or AOD measurements as defined in 11.21.6.4.2.1. To perform an FTM exchange that does require AOD or AOD measurements, it follows the procedure in 11.21.6.4.2.3. In both these cases, when the first path AWV setting is not used in the exchange, the Trigger field shall be set to 1 in the FTM Request frame that initiates the exchange. In both cases the same AWV used for data transfer between the STAs shall be used for transmission and reception of the preamble and data portion of the PPDUs.

An EDMG ISTA initiates an FTM exchange using the first path AWV setting by setting the value of the Trigger field of the FTM Request frame that initiates the exchange to 2. An EDMG ISTA may send an FTM Request frame with the trigger set to 2 only if the RSTA has set the First Path Beamforming Training Supported subfield to 1 in the Beamforming field of the EDMG Capabilities element and the ISTA and RSTA have performed beamforming training for first path as defined in 10.41.10.6. When the trigger is equal to 2 in the FTM request frame that initiates the burst, the first path AWV settings shall be used in transmission and reception of FTM and Ack frames sent by the ISTA and RSTA during the FTM burst.

An EDMG ISTA sets a value for the Ranging Priority subfield of the FTM Parameters field of the FTM Parameters element in the IFTMR frame from the values in Table 9-323. The RSTA responds to this request by setting a value for the Ranging Priority subfield of the FTM Parameters field of the FTM Parameters element in the IFTM frame from Table 9-324 in response. How an RSTA supports ranging priority is implementation dependent.

11.21.6.4.2.3 DMG/EDMG AOA/AOD measurement exchange

A DMG ISTA/RSTA pair that has agreed on performing direction measurement by agreeing on either R2I AOA, I2R AOD, I2R AOA, or R2I AOD shall add TRN fields to FTM exchanges in the burst according to the Direction Measurement Density sent by the RSTA in the IFTM frame.

A DMG ISTA/RSTA pair that has agreed on either R2I AOA, I2R AOD, I2R AOA, or R2I AOD using the procedure described in 11.21.6.3.7 shall be denoted as Direction Measurement FTM pair.

An FTM exchange in which the Trigger field in the FTM Request that initiated the exchange is set to 2 is denoted as a first path AWV FTM exchange.

In a Direction Measurement FTM pair, the first measurement in the burst shall include either R2I AOA, I2R AOD, I2R AOA, or R2I AOD for all values of the Direction Measurement Density.

In a Direction Measurement FTM pair that agreed on R2I AOA, the RSTA shall add a TRN field to the FTM frames in the exchanges specified by the Direction Measurement Density field by setting the TRN_LEN/ EDMG_TRN_LEN to the value of the L_RX field sent by the ISTA and PPDU_TYPE/EDMG_PPDU_TYPE to 0. In a first path AWV FTM exchange the RSTA shall also set the TXVECTOR parameter FIRST_PATH_AWV_TRN to FIRST_PATH_AWV_ON_TRN in the FTM frames it sends to the ISTA. The ISTA may receive the TRN field using implementation dependent AWV settings.

In a Direction Measurement FTM pair that agreed on I2R AOA, the ISTA shall add a TRN field to the Ack frames in the exchanges specified by the Direction Measurement Density field by setting the TRN_LEN/ EDMG_TRN_LEN to the value of the L_RX field of the DMG Direction Measurement Parameters received from the RSTA and PPDU_TYPE/EDMG_PPDU_TYPE to 0. In a first path AWV FTM exchange the ISTA shall also set the TXVECTOR parameter FIRST_PATH_AWV_TRN to FIRST_PATH_AWV_ON_TRN in

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the Ack frames it sends to the RSTA. The RSTA may receive the TRN field using implementation dependent AWV setting. The RSTA shall provide the AOA measurement results in the Direction Measurement Result element included in the next FTM frame sent to the ISTA.

In a Direction Measurement FTM pair that agreed on R2I AOD, the RSTA shall add a TRN field to the FTM frames in the exchanges specified by the Direction Measurement Density field by setting the TRN_LEN/ EDMG_TRN_LEN to a nonzero value and PPDU_TYPE/EDMG_PPDU_TYPE to 1. In a first path AWV FTM exchange the RSTA shall also set the TXVECTOR parameter FIRST_PATH_AWV_TRN to FIRST_PATH_AWV_ON_TRN in the FTM frames it sends to the ISTA. The ISTA shall receive the TRN field using the first path AWV setting. The RSTA may use implementation dependent AWV (such as sectors) in the TRN field.

In a Direction Measurement FTM pair that agreed on I2R AOD, the ISTA shall add a TRN field to the Ack frames in the exchanges specified by the Direction Measurement Density by setting the TRN_LEN/ EDMG_TRN_LEN to a nonzero value and PPDU_TYPE/EDMG_PPDU_TYPE to 1. In a first path AWV FTM exchange the ISTA shall also set the TXVECTOR parameter FIRST_PATH_AWV_TRN to FIRST_PATH_AWV_ON_TRN in the Ack frames it sends to the RSTA. The RSTA shall receive the TRN field using the first path AWV setting. The ISTA may use implementation dependent AWV (such as sectors) in the TRN field. The RSTA shall set the Best AWV ID field in the FTM frames sent to the ISTA following these Ack frames to the AWV ID or the Best Sector Index of the TRN field (if the Ack was an EDMG/DMG PPDU, respectively). If the RSTA has set the AOD Channel Measurement Feedback subfield to 1 in the DMG Direction Measurement Capabilities field, it shall also include a Channel Measurement Feedback Type field and a Channel Measurement Feedback field in the FTM frames sent to the ISTA following the reception of the Ack frames that its RXVECTOR parameter PPDU_TYPE is equal to TRN-T or EDMG_PPDU_TYPE equal to EDMG-TRN-T, and TRN-LEN greater than 0 or EDMG-TRN-LEN greater than 0.

If the Trigger field in the FTMR frame that initiated an FTM exchange in a Direction Measurement FTM pair is equal to 2, all the preamble and PSDU parts of the PPDUs sent during the exchange shall be transmitted and received using the first path AWV setting. The TRN fields of these PPDUs shall also be transmitted and received using the first path AWV setting, except for AOD TRN fields, which may be transmitted with changing AWV setting, and AOA TRN fields, which may be received with changing AWV setting.

11.21.6.4.2.4 DMG AOD feedback exchange after an FTM exchange

When an ISTA and RSTA agreed on performing an R2I AOD measurement FTM exchange as described in 11.21.6.4.2.3 the ISTA needs to send AOD measurement results to the RSTA, so that the RSTA may use these to generate the AOD estimates and send the results back to the ISTA.

To enable this, the ISTA collects the best sector results throughout the burst.

After the burst the ISTA shall send an FTM frame containing a Multiple AWV ID element with the Trigger field set to 0, to the RSTA. The Number Of Best AWV ID field in the Multiple AWV ID element shall be set to the number of FTM frames in the burst that contained a TRN field enabling AOD estimation. When the RSTA is ready with the AOD results, it should send an FTM frame containing a Multiple AOD Feedback element containing the AOD results. The Number Of AOD Feedbacks field in the Multiple AOD Feedback element shall be set to the value of the Number Of Best AWV ID field in the Multiple AWV ID element in the FTM frame from the ISTA that elicited the Multiple AOD feedback.

11.21.6.4.2.5 DMG LOS assessment for EDCA based ranging measurement exchange

A LOS assessment FTM exchange may provide an ISTA with information about whether the link with the ISTA is over a non-LOS path. A LOS assessment FTM exchange is a DMG FTM burst as defined in 11.21.6.4.2.2 or 11.21.6.4.2.3 in which one FTM frame from the RSTA to the ISTA is a LOS assessment FTM PPDU. A LOS assessment FTM burst over the non-first path AWV is identified by the RSTA setting the FTM

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

trigger to 3 at the FTMR. A LOS assessment FTM burst over the first path AWV is identified by setting the FTM trigger to 4. An ISTA shall not initiate an FTM burst by an FTMR with the trigger set to 3 or 4 unless the RSTA has indicated it may participate in such exchange by setting to 1 the LOS Assessment TX subfield in the DMG Direction Measurement Capabilities field of the DMG Capabilities element.

A LOS assessment FTM PPDU is defined as a PPDU that contains an FTM frame that is sent with the TXVECTOR parameters set as follows: DUAL_POLARIZATION_TRNS set to 1, EDMG_TRN_LEN set to a value greater than 0, and EDMG_PPDU_TYPE set to EDMG-TRN-R.

The RSTA and the ISTA shall switch polarization while transmitting and receiving the TRN field of the LOS assessment FTM PPDU as described in 28.9.2.2.5.

If the RSTA has set the LOS Assessment RX subfield to 1 in the DMG Direction Measurement Capabilities field, the ISTA shall respond to a LOS assessment FTM PPDU with a LOS Assessment Ack PPDU.

A LOS Assessment Ack PPDU is defined to be a PPDU that contains an Ack frame and has the DUAL_POLARIZATION_TRNS field set to 1, the EDMG_TRN_LEN set to a value greater than 0 and the EDMG_PPDU_TYPE set to EDMG-TRN-R. The ISTA and the RSTA shall switch polarization while transmitting and receiving the TRN field of the LOS assessment FTM PPDU and the LOS assessment Ack PPDU as described in 28.9.2.2.5. The RSTA shall send a channel measurement element based on the measurements it performed on the Ack PPDU TRN field in the next FTM frame sent to the ISTA.

11.21.6.4.2.6 DMG first path AWV for EDCA based ranging measurement exchange

A first path AWV FTM burst is started when an ISTA sends the RSTA an FTM Request frame with Trigger field set to 2. An EDMG ISTA may send an FTM Request frame with the trigger set to 2 only if the RSTA has set the First Path Training Supported subfield to 1 in the Beamforming field of the EDMG Capabilities and the ISTA and RSTA have performed beamforming training for first path as defined in 10.41.10.6. All the FTM frames sent from the RSTA to the ISTA during the FTM burst and all the Ack frames sent from the RSTA to the ISTA in response to the FTM frame shall have the setting described in Table 11-17, except when used for AOD and AOA estimation.

Table 11-17—TXVECTOR parameter setting for first path AWV FTM exchange

TXVECTOR Parameter	Value
EDMG_PPDU_TYPE	EDMG-TRN-T
EDMG_TRN_LEN	1
RX_TRN_PER_TX_TRN	1
EDMG_TRN_P	0
EDMG_TRN_M	3
EDMG_TRN_N	3
TRN_SEQ_LENGTH	Normal
FIRST_PATH_AWV_TRN	FIRST_PATH_AWV_ON_TRN

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The setting of the TXVECTOR parameters when the frames are used for AOA and AOD estimation is described in 11.21.6.4.2.3.

When an FTM frame is sent with the TXVECTOR parameter FIRST_PATH_AWV_TRN set to FIRST_PATH_AWV_ON_TRN, the Ack frame sent in response to this frame shall have the TXVECTOR parameter FIRST_PATH_AWV_TRN set to FIRST_PATH_AWV_ON_TRN. In both these frames the TRN field shall be received by the ISTA and RSTA using the first path AWV receive antenna setting.

11.21.6.4.2.7 DMG secure measurement exchange for EDMG STAs

Setup of the Secure EDMG Measurement exchange is described in 11.21.6.3.6. The Secure EDMG Measurement exchange protocol follows the procedure as described in 11.21.6.4.2 with the following changes:

- The Protected FTM Request frame shall be used by the ISTA to initiate the exchange.
- The ISTA shall use the Protected FTM frame during the exchange.
- The PPDUs carrying the Protected FTM frames transmitted by the RSTA and the Acks transmitted by the ISTA shall be based on the format as described in 28.9.3. In these PPDUs, the TXVECTOR parameter SECURED_TRN shall be set to SECURED_TRN.
- The PPDU carrying the protected FTM frames transmitted by the responder to initiator shall use the first path AWVs obtained during first path beamforming training as described in 10.41.10.6.
- The PPDU carrying the Ack frame transmitted by the initiator to the responder shall use the first path AWVs obtained during first path beamforming training as described in 10.41.10.6.
- If the Ack frame for an FTM frame is not received, the RSTA may retransmit the FTM frame. In this case, the RSTA shall send an FTM frame with the same Action frame body as the FTM frame for which the Ack was not received, except for updating the Dialog Token field if it was nonzero, and a new Secure TRN Sequence (see 12.2.12) shall be used. The Sequence Number field in the MAC header is also updated.

The following rules apply to the FTM retransmission of the secure EDMG measurement exchange:

a) The t2 measured by the RSTA and the t4 measured by the ISTA shall be based on the secure TRN subfields. For verification of security, the RSTA and ISTA should estimate the time separately on each secure TRN subfield and verify that values estimated on different TRN subfields are equal up to a small estimation error.

b) If FTM retransmission is successful, the ISTA may derive the RTT using the received TOA (t4) and TOD (t1) values included in the retransmitted FTM frame, and t2 and t3 values estimated locally in the prior (or preceding) FTM.

c) During the FTM retransmission, the t2 value estimated by the ISTA shall not be used for RTT calculation in the subsequent FTM. This is because the t2 was estimated by correlating two unmatched secure TRNs as a result of FTM retransmission.

d) During the FTM retransmission, the t4 value estimated by the RSTA shall not be included in the subsequent FTM frame. This is because the t4 was estimated by correlating two unmatched secure TRNs as a result of FTM retransmission.

e) Due to rules c) and d), the FTM immediately after the FTM retransmission shall not be used by an ISTA for RTT calculation.

f) A successful FTM retransmission shall only be counted towards to the total number of FTMs Per Burst value.

If an RSTA does not perform FTM retransmission, so that the maximum number of FTM frame retransmissions the RSTA might attempt is zero, the RSTA shall send a new FTM frame (with TOA=0, TOD=0, updated Dialog Token) with new Secure TRN (associated with the updated dialog token) appended when an FTM transmission in a secure EDMG FTM exchange fails.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA shall maintain the Dialog Token Counter, and update the Dialog Token Counter to (Dialog Token field value – 1) mod 254 + 1, where the Dialog Token field value corresponds to the value of the Dialog Token field either in the lastly transmitted FTM frame if the STA is an RSTA or in the lastly received FTM frame if the STA is an ISTA.

A STA transmitting an EDMG secure ranging PPDU to a peer STA shall set the TXVECTOR parameters as follows:

— The SECURED TRN parameter is set to SECURED_TRN.
— The SECURE_TRN_SEQUENCE parameter contains the Secure TRN bit sequences associated with the Dialog Token Counter.

After transmitting an EDMG secure ranging PPDU, a STA's MAC sublayer issues a PHY-RXTRNSEQUENCE.request with a TRNVECTOR parameter that provides the TRN sequence associated with the Dialog Token Counter.

When an RSTA transmits an EDMG secure ranging PPDU, it shall include the Protected FTM frame in which the Dialog Token field is set to the Dialog Token Counter.

An ISTA shall transmit an Ack frame to the received Protected FTM frame as an EDMG secure ranging PPDU. An ISTA shall discard the timestamps measured from an EDMG secure ranging PPDU if the Dialog Token field in the Protected FTM frame in the EDMG secure ranging PPDU does not match its Dialog Token Counter.

NOTE—It is recommended that an ISTA or RSTA discards ranging measurements when it detects that the transmit center frequency offset between the ISTA and the RSTA exceeds the allowed tolerance from the values specified in 20.3.3.2.1.

11.21.6.4.3 TB ranging measurement exchange

11.21.6.4.3.1 General

TB ranging is the dynamic trigger-based variant of the FTM procedure. The TB ranging measurement exchange consists of one or more scheduled availability windows. The TB ranging measurement exchange is dynamic, as the actual number of ISTAs participating in the measurement exchange can vary across availability windows. Each ISTA that is assigned to the scheduled availability window may participate in or skip the corresponding measurement exchange. The availability windows are scheduled periodic time windows assigned to ISTAs during negotiation (see 11.21.6.3.3).

Within each availability window the RSTA and ISTAs shall not transmit or trigger transmission of any Data frames; they shall only perform ranging activities related to Polling, Measurement Sounding, and Measurement Reporting phases, as well as signaling of modification of availability window parameters; see 11.21.6.5.1, and TB ranging session termination, see 11.21.6.6.2. Each availability window by default consists of a single TXOP and may be extended to multiple TXOPs by announcement, if a single TXOP is insufficient to accommodate all ISTAs that responded to the poll; see 11.21.6.4.3.2, and 11.21.6.4.3.3. Each availability window of the TB ranging measurement exchange consists of one or more triplets of sequential phases: Polling phase, Measurement Sounding phase, and Measurement Reporting phase. Figure 11-48 shows an example of two availability windows, each composed of a single triplet of Polling, Measurement Sounding, and

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Measurement Reporting phases. An RSTA and ISTA participating in TB ranging shall perform any Polling, Measurement Sounding, and Measurement Reporting phases only within the availability windows.

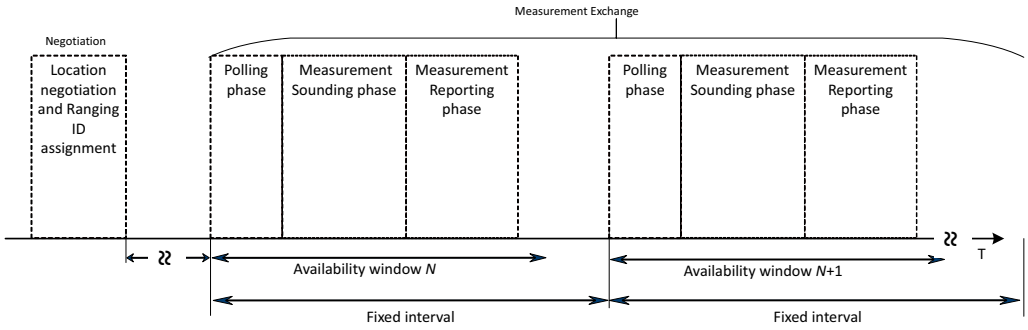

Figure 11-48—TB ranging availability windows each with one instance of a polling/ sounding/reporting triplet

Each availability window typically contains a single poll, where the RSTA should poll all the ISTAs assigned to that availability window. If the available bandwidth is insufficient to allow for the polling of all ISTAs assigned to the availability window with one poll, the RSTA shall indicate that one or more extra polling/ sounding/reporting triplets can be expected within the availability window (see example in Figure 11-49 , and

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Figure 11-50 . All instances of polling/sounding/reporting triplets shall be completed before the end of the availability window.

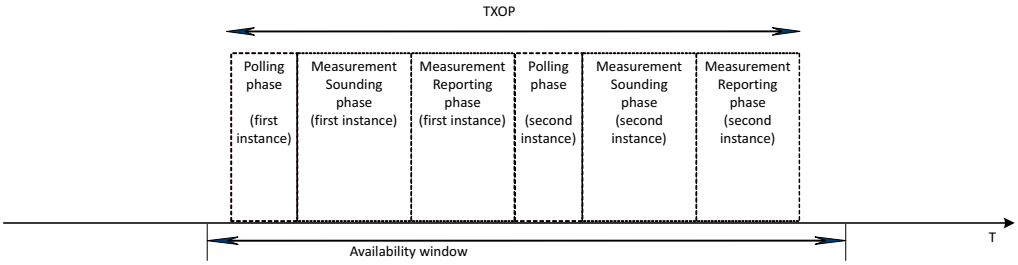

Figure 11-49—TB ranging availability window with two instances of polling/sounding/ reporting triplets within a single TXOP

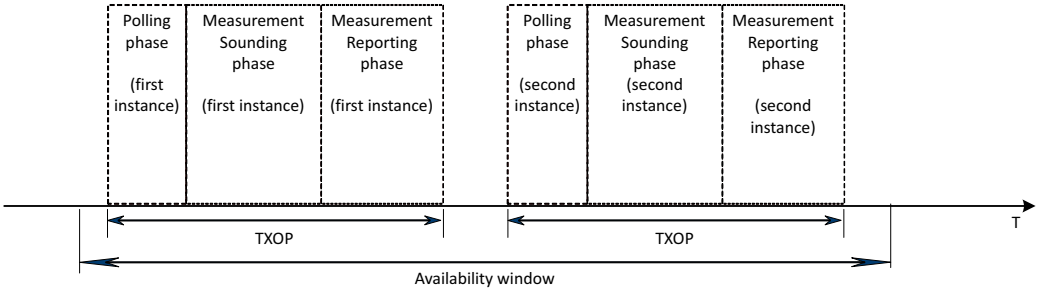

Figure 11-50—TB ranging availability window with two instances of polling/sounding/ reporting triplets in separate TXOPs

During the availability window, measurement resources and results shall be made available to each ISTA whose poll response was received at the RSTA; see 11.21.6.4.3.3 and 11.21.6.4.3.4. This may also lead to extra instances of polling/sounding/reporting triplets, even if all ISTAs assigned to this availability window were polled in the first Polling phase instance (e.g., if the RSTA is not able to accommodate all ISTAs that responded in a single measurement sounding phase instance; see 11.21.6.4.3.3).

The timestamps reported within each measurement sounding phase shall be derived from a clock that runs continuously during the measurement sounding phase.

If there is a discontinuity in the clock for the FTM timestamping between two reported TOD timestamps, then the TOD Not Continuous subfield in the TOD Error field of the LMR frame shall be set to 1. Otherwise it shall be set to 0.

NOTE—In some use cases it is of interest to have a clock that runs continuously across subsequent ranging availability windows. For this reason it is desirable for the clock for the FTM timestamping to run continuously.

Within each availability window, an RSTA shall use an AID or Ranging Session ID (RSID) to identify an associated or unassociated ISTA, respectively. The AID and RSID assignment shall be nonconflicting and shall have the same size and valid address space (as defined in 9.4.1.8 and 26.17.4). The RSID usage shall

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

follow the same rules as that of AIDs for HE operations. The RSIDs are assigned to unassociated ISTAs during the FTM negotiation; see 11.21.6.3.

An RSTA shall follow the rules defined in 26.5.2 when transmitting any Trigger frames of variant Location for TB ranging with the following rules:

— A Ranging Trigger frame shall be carried in an S-MPDU if the Ranging Trigger frame is carried in a VHT PPDU or HE PPDU.
— An RSTA shall not transmit a Ranging Trigger frame in a VHT MU PPDU or HE MU PPDU.

An RSTA shall not transmit a Sounding Ranging Trigger frame soliciting an HE TB Ranging NDP that uses UL MU-MIMO, that is, where the same RU is allocated to multiple ISTAs, to any ISTA from which it has not received a TB specific subelement in the Ranging Parameters element with the Full Bandwidth UL MU-MIMO field equal to 1.

If required, an ISTA shall transmit any FTM Request frames outside of availability windows allocated to itself. Inside availability windows allocated to itself, an ISTA shall not transmit any frame except when assigned UL resources by a TF transmitted by the RSTA.

An RSTA, in which dot11MultiBSSIDImplemented is true, and that transmits a Ranging Trigger frame or a Ranging NDP Announcement frame to a set of ISTAs, in which at least two ISTAs have a TB ranging measurement exchange with different BSSIDs in the Multiple BSSID set of the RSTA shall set the TA field of these frames to the transmitted BSSID. Any ISTA that negotiates a TB ranging measurement exchange session with a nontransmitted BSSID of an RSTA shall support the reception of a Control frame with TA equal to the transmitted BSSID.

An ISTA shall follow the rules defined in 26.5.2 when transmitting any HE TB PPDUs for TB ranging with the exceptions defined in 11.21.6.4.3.2, 11.21.6.4.3.3, and 11.21.6.4.3.4.

The FTM protocol for a TB ranging measurement exchange and its relationship with the SME and MLME interface is shown in Figure 11-51 .

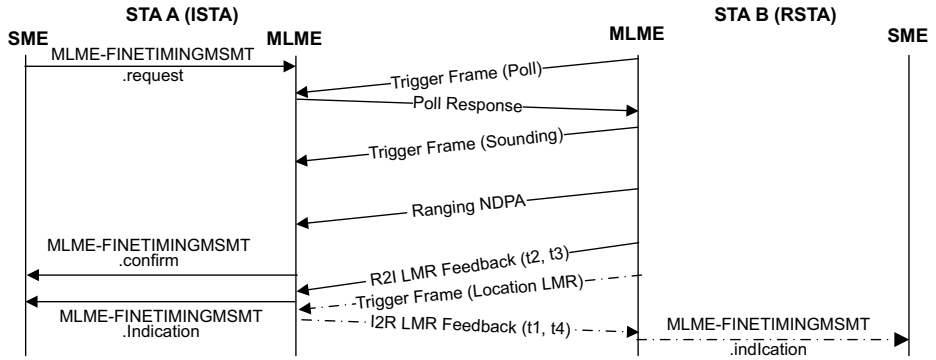

Figure 11-51—FTM primitives and timestamps reporting capture for TB ranging measurement exchange

11.21.6.4.3.2 Polling phase of TB ranging

The Polling phase is the first phase of each polling/sounding/reporting triplet.

In each Polling phase instance, the RSTA shall transmit a Poll Ranging Trigger frame, see 9.3.1.22.10. Once a response is received, the RSTA shall proceed to the Measurement Sounding phase; otherwise it may transmit

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

additional Poll Ranging Trigger frames, until it receives a response from at least one ISTA. The RSTA shall allocate each RU in the TF Ranging poll to only one ISTA. Any ISTA addressed by a User Info field in a TF Ranging Poll frame that intends to participate in the measurement sequence within this availability window shall send a CTS-to-self in an S-MPDU within an HE TB PPDU in its designated RU allocation as identified in the TF Ranging Poll frame, otherwise shall not send a CTS-to-self to avoid resource allocation in this measurement sequence; see Figure 11-50 .

If the available bandwidth does not allow for the polling of all ISTAs assigned to this availability window using a single TF Ranging Poll frame, the RSTA shall attempt to schedule one or more extra polling/sounding/reporting triplets within the availability window. The RSTA shall indicate the extra polling/sounding/reporting triplets by setting the More TF subfield in the Common Info field to 1 and the RA field to the broadcast address in the TF Ranging Poll frame, and in TFs in subsequent Polling, Measurement Sounding, and Measurement Reporting phases in the same availability window. If the RSTA had set the More TF subfield to 1 in the preceding Ranging Trigger frame, and if there are no additional polling/sounding/reporting triplets in the same availability window, the RSTA shall set the More TF subfield in the Common Info field to 0 and the RA field to the broadcast address in the next Ranging Trigger frame within that availability window. On receipt of such a frame, an ISTA that has not been addressed by a User Info field in the TF, may enter doze state, if no other condition requires this STA to remain awake. Any extra polling/sounding/reporting triplets can either be transmitted in the same TXOP (see example in Figure 11-49) or a new TXOP (see example in Figure 11-50), depending on the maximum allowed TXOP duration and the predicted length of the extra instances of polling/sounding/reporting triplets.

11.21.6.4.3.3 Measurement Sounding phase of TB ranging

The measurement-sounding phase commences SIFS time after the Polling phase and is the second phase of each polling/sounding/reporting triplet; see Figure 11-52 . The measurement sounding phase consists of one or more Sounding Ranging Trigger frames (see 9.3.1.22.10) allocating uplink resources to one or more ISTAs; see Figure 11-48 and Figure 11-50 . The Ranging variant Trigger frame of Sounding subvariant is called the TF Ranging Sounding frame. Each TF Ranging Sounding frame shall allocate uplink resources for one or more ISTAs' I2R NDP multiplexed in the spatial stream domain covering the full bandwidth. The format of the I2R NDP is an HE TB Ranging NDP; see 27.3.19.2. SIFS time after receiving the last I2R NDP, the RSTA shall transmit an NDP Announcement frame followed by an R2I NDP; the Ranging NDP Announcement frame is described in 9.3.1.19 and the R2I NDP is an HE Ranging NDP, as described in 27.3.19.1. Figure 11-52 shows an availability window with an RSTA and two ISTAs (ISTA 1 and ISTA 4) responding to the poll. The

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Ranging NDP Announcement frame's STA Info fields specify all the ISTAs that will use the R2I NDP, which shall include the ISTAs that were allocated uplink resources in the measurement sounding phase.

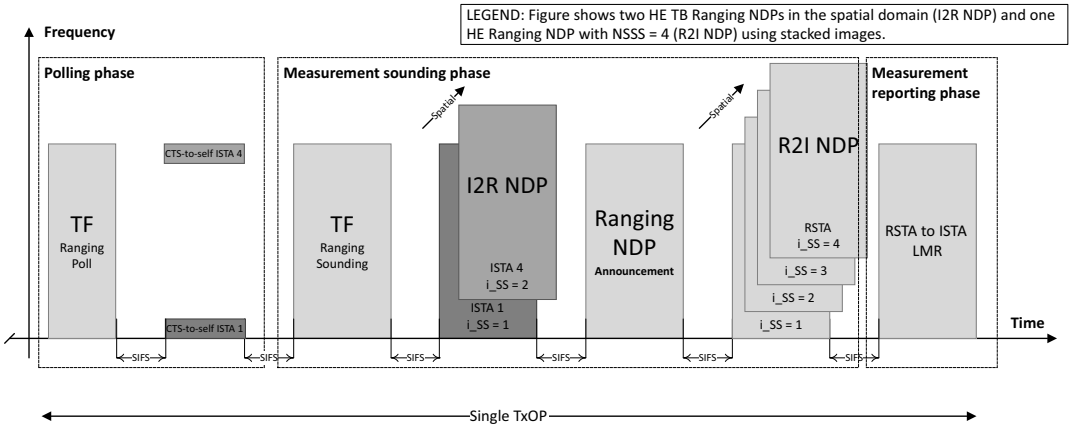

Figure 11-52—TB ranging availability window with two ISTAs

The RSTA shall select a bandwidth value for the measurement sounding phase that is less than or equal to the RSTA Assigned Max Bandwidth of each of the ISTAs that are being allocated resources during this measurement instance. It may be different from the bandwidth used in the Polling phase, but shall adhere to the rules of multiple frame transmission in an EDCA TXOP; see 10.23.2.8.

The RSTA shall set the TXVECTOR parameter CH_BANDWIDTH of the Trigger frame Ranging Sounding to that same bandwidth and use the same value for the UL BW subfield of the Common Info field of said Trigger frame. When transmitting the Ranging NDP Announcement frame and R2I NDP, the RSTA shall set the TXVECTOR parameter CH_BANDWIDTH to that same bandwidth.

In the TF Ranging Sounding, the RSTA shall set the SS Allocation subfield and the I2R Rep subfield of the User Info fields corresponding to each of the ISTAs triggered by the Trigger frame in the following way:

— The Number of Spatial Streams in each SS Allocation subfield shall not exceed the *RSTA Assigned I2R STS ≤ 80 MHz* for the corresponding ISTA, if the UL BW subfield in the Common Info field indicated a bandwidth less than or equal to 80 MHz, and not exceed the *RSTA Assigned I2R STS > 80 MHz* for the corresponding ISTA otherwise.

— All the I2R Rep subfields in the User Info fields of the TF Ranging Sounding shall be set to the same value. This value indicates the number of LTF repetitions in the I2R NDP preamble and shall not exceed any of the *RSTA Assigned I2R Rep* corresponding to the ISTA triggered by this Trigger frame.

— The product of the number of LTF repetitions, indicated in each of the I2R Rep subfields of the User Info fields, and the number of HE-LTF symbols, indicated in the Number Of HE-LTF Symbols And Midamble Periodicity subfield in the Common Info field, shall not exceed the *RSTA Assigned I2R LTF Total* for any of the ISTA triggered by this Trigger frame.

After transmission of the TF Ranging Sounding, the RSTA's MAC sublayer shall issue a PHY-RXLTFSEQUENCE.request primitive with an LTFVECTOR containing the following parameters:

— The SECURE_LTF_FLAG parameter set to 0.

— The LTF_NSTS and LTF_REP parameter vectors set to the same values as indicated, respectively, by the SS Allocation and I2R Rep subfields of all the User Info fields.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Similarly, in the Ranging NDP Announcement frame, the RSTA shall set the R2I NSTS subfield and R2I Rep subfield of the STA Info fields corresponding to each of the ISTAs addressed by that frame in the following way:

— The R2I NSTS subfield value shall not exceed the *RSTA Assigned R2I STS ≤ 80 MHz* for the corresponding ISTA, if the TXVECTOR parameter CH_BANDWIDTH for this Ranging NDP Announcement frame is less than or equal to 80 MHz, and not exceed *RSTA Assigned R2I STS > 80 MHz* for the corresponding ISTA otherwise.

— The number of LTF repetitions in the R2I Rep subfield shall be set to a value not to exceed the *RSTA Assigned R2I Rep* for the corresponding ISTA.

— The combination of the values of the R2I NSTS and the R2I Rep shall not lead to a total number of LTF that exceeds the *RSTA Assigned R2I LTF Total* for each corresponding ISTA.

After reception of the Ranging NDP Announcement frame, the ISTAs' MAC sublayer shall issue a PHY-RXLTFSEQUENCE.request primitive with an LTFVECTOR containing the following parameters:

— The SECURE_LTF_FLAG parameter set to 0.

— The LTF_NSTS and LTF_REP parameters set to the same values as indicated, respectively, by the R2I NSTS and R2I Rep subfields of the STA Info field addressed to it.

The RSTA shall set a different value than the previous transmission in the Sounding Dialog Token Number field in its transmitted Ranging NDP Announcement frame as part of each Measurement Sounding phase. Measurement instances are associated with the Sounding Dialog Token Number field value.

The RSTA may schedule some ISTAs that replied during the Polling phase to the first measurement sounding phase instance and other ISTAs to one of possibly multiple extra measurement sounding phase instances; see Figure 11-49 and Figure 11-50 . The RSTA shall only schedule measurement sounding resources to an ISTA in a measurement sounding instance if a valid poll response was received from that ISTA in the corresponding Polling phase instance. This may require an RSTA to poll an ISTA multiple times. This is necessary, for example, if different ISTAs have varying, incompatible, RSTA Assigned Max Bandwidth values or if the RSTA wants to limit the time duration of each range measurement sounding instance.

Both RSTA and ISTA perform RTT measurements by capturing the timestamps of the NDP. The ISTA shall record the time at which the I2R NDP is transmitted (t1). The RSTA shall then capture the time at which the I2R NDP arrives (t2) and shall record the time at which the R2I NDP is transmitted (t3). The ISTA shall finally capture the time at which the R2I NDP arrives (t4); see Figure 11-53 . The timestamp values t2 and t3 shall be

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

measured according to the RSTA's clock (i.e., without applying any frequency offset correction to the time basis).

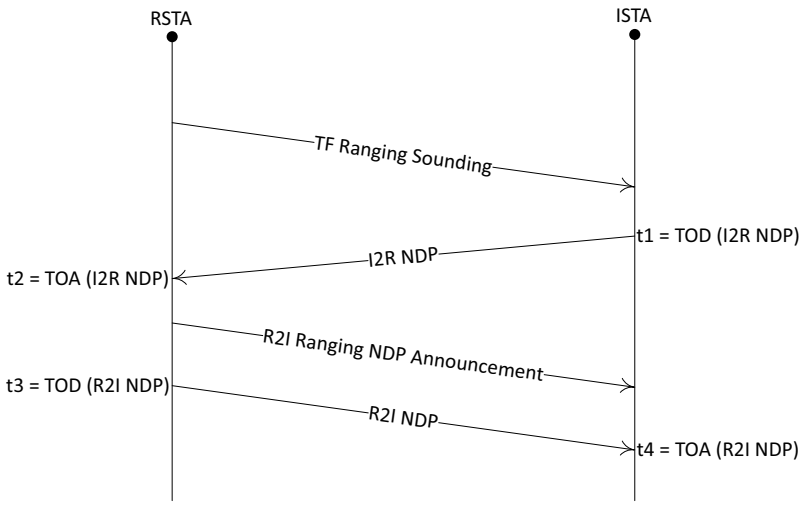

Figure 11-53—Timing diagram of a measurement sounding phase in TB ranging

The Round Trip Time (RTT_ISTA) observed by ISTA is defined as:

$$RTT_{ISTA} = [(t4 - t1) - (t3' - t2')]$$

where t3' and t2' are the time at which the R2I NDP was transmitted and the time at which the I2R NDP was received, respectively, as converted by the ISTA from the RSTA's time basis to its own time basis.

The mechanism by which the ISTA derives t3' and t2' from the TOD and TOA fields of the relevant R2I LMR (see 11.21.6.4.3.4) is implementation dependent.

When the I2R LMR Feedback is negotiated, the RSTA can compute the RTT as:

$$RTT_{RSTA} = [(t4' - t1') - (t3 - t2)]$$

where t1' and t4' are the time at which the I2R NDP was transmitted and the time at which the R2I NDP was received, respectively, as converted by the RSTA from the ISTA's time basis to its own time basis. The mechanism by which the RSTA derives t4' and t1' from the TOD and TOA fields of the relevant I2R LMR is implementation dependent; see 11.21.6.4.3.4.

NOTE 1—When using CFO in the conversion from the ISTA's time basis to the RSTA's, the RSTA uses the CFO reported in the CFO Parameter field of the I2R LMR.

NOTE 2—Refer to 27.3.15.3 for carrier frequency offset (CFO) correction requirements for HE TB PPDU transmission.

In an LMR, the TOA field contains a timestamp that represents the time, with respect to a time base, at which the start of the preamble of the corresponding NDP arrived at the receive antenna connector. The TOD field contains a timestamp that represents the time, with respect to the same time base, at which the start of the preamble of the corresponding NDP appeared at the transmit antenna connector.

If the measurement sounding phase includes more than a single TF Ranging Sounding frame (see Figure 11-54) each ISTA and RSTA pair shall refer to the t1 and t2 of the I2R NDP transmitted by that ISTA, while t3 and t4 shall be based on the single R2I NDP received by all ISTAs; see Figure 11-55 .

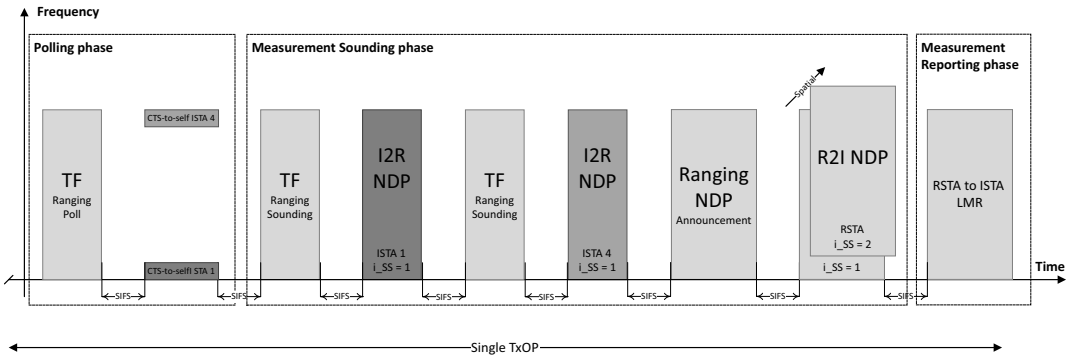

Figure 11-54—TB ranging availability window with multiple TF Ranging Sounding frames

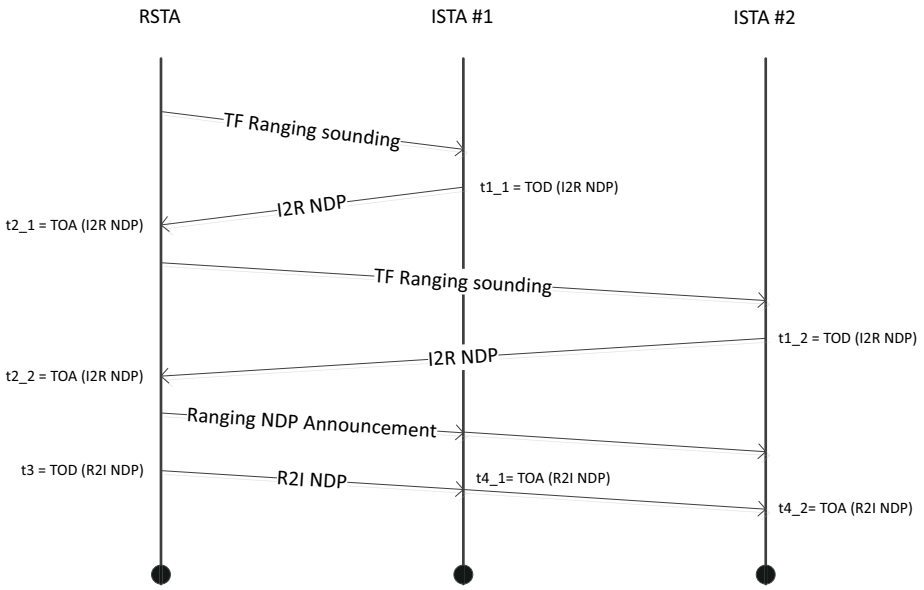

Figure 11-55—Measurement sounding phase with I2R time division multiplexing

If due to retransmission an ISTA receives multiple TF Ranging Sounding frames and transmits multiple I2R NDPs, the ISTA and RSTA shall refer to the t1 and t2 of the I2R NDP last transmitted.

The uplink power control, timing, and frequency synchronization requirements of unassociated STAs performing TB ranging shall follow the same rules as those of associated HE STAs.

To aid in synchronizing the TSF time at the ISTAs, the RSTA maintains a trigger poll counter. Before transmitting a TF Ranging Poll frame, the RSTA shall increase the trigger poll counter by one (modulo 8) and set the Token subfield of the Trigger Dependent Common Info subfield to the value of the trigger poll counter.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When transmitting a Ranging NDP Announcement frame as part of the TB ranging measurement exchange, an RSTA shall include a value in the Partial TSF subfield in the STA Info field with the AID11 subfield equal to 2044, that is equal to the RSTA's TSF[21:6] at the time of transmission of the preceding TF Ranging Poll frame. Specifically, the time that the first data symbol of the PSDU of said frame was transmitted to the PHY plus the RSTA's delays through its local PHY from the MAC-PHY interface to its interface with the WM.

Additionally, the RSTA shall set the Token subfield in the STA Info field with the AID11 subfield equal to 2044 to the same trigger poll counter value as the Token subfield in the TF Ranging Poll frame whose partial TSF time is carried in the Ranging NDP Announcement frame.

NOTE 3—An ISTA that tries to synchronize to the RSTA's TSF time will need to keep track of the difference between its local TSF[63:22] and the RSTA's TSF[63:22] when updating the TSF[21:6]. When receiving a partial TSF value in a received Ranging NDP Announcement frame from the RSTA, to synchronize its TSF time with the RSTA's TSF time in order to determine the start of a subsequent TB ranging availability window:

— The ISTA should check if its TSF[21:6] at the reception of a TF Ranging Poll frame was larger than the received Partial TSF and the absolute difference is more than 2^{15}, then the ISTA should increase the RSTA's tracked TSF [63:22] value by 1.

— If the ISTA's TSF [21:6] at the reception of the TF Ranging Poll frame is less than the Partial TSF and the absolute difference is more than 2^{15}, the ISTA should decrease the RSTA's tracked TSF [63:22] value by 1.

11.21.6.4.3.4 Reporting phase of TB ranging measurement

The last phase of each polling/sounding/reporting triplet is the measurement reporting phase, which is transmitted a SIFS time after the measurement sounding phase; see Figure 11-50 . The measurement results shall be carried in LMR frames; see 9.6.7.49. LMR frames shall carry measurement results from the RSTA to the ISTA, and if negotiated also from the ISTA to the RSTA; see Figure 11-56 . If the Range Reporting is performed in the context of a Secure FTM Session, see 11.21.6.3, the corresponding LMR and FTM (see 11.21.6.5.1) frames shall be transmitted using Protected Fine Timing Action frames, and see 9.6.34.

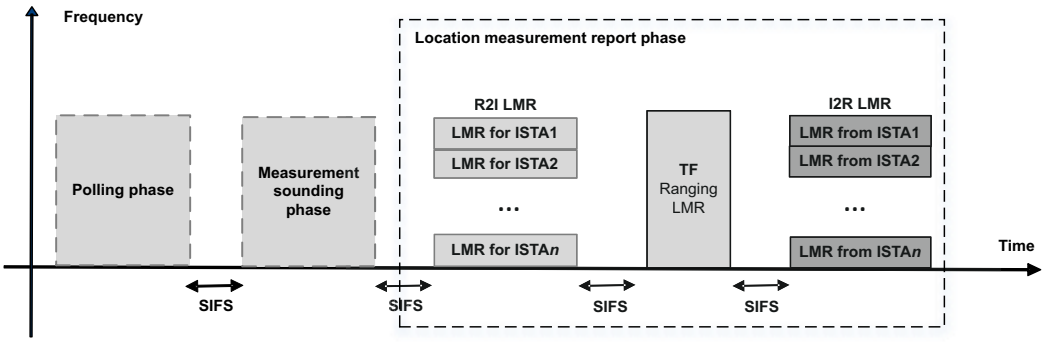

Figure 11-56—TB ranging measurement reporting phase with bidirectional LMR feedback for *n* ISTAs

The feedback type of the I2R and R2I LMRs may be either immediate (i.e., from the current availability window) or delayed (i.e., from the last availability window in which the ISTA responded to the TF Ranging Poll frame and the RSTA allocated resources to that ISTA during the measurement sounding phase). The LMR feedback (immediate/delayed) is indicated by the RSTA during the negotiation (see 11.21.6.3.3).

The Dialog Token field in the LMR frame shall be identical to the Sounding Dialog Token field in the corresponding Ranging NDP Announcement frame in the Measurement Sounding phase from which the reported TOA and TOD values were measured; see 11.21.6.4.3.3.

NOTE 1—LMR feedback is carried in Action No-Ack frames and is therefore neither acknowledged nor retransmitted; see 9.6.7.49.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The RSTA shall transmit an R2I LMR to all ISTAs that were allocated resources in the preceding measurement sounding phase. All the R2I LMR frames shall be carried in one HE MU PPDU, where each RU contains only one user; if there is only one R2I LMR it may be carried in an HE SU PPDU.

If I2R LMR was negotiated, the RSTA shall assign uplink resources to the ISTAs using a Report Ranging Trigger frame; see 9.3.1.22.10. The Ranging variant Trigger frame of report subvariant is called the TF Ranging LMR.

A TB ranging measurement reporting phase including the optional I2R LMR is illustrated in Figure 11-56 . If the I2R LMR was negotiated by one or more ISTAs, then SIFS time after transmitting out the R2I LMR, the RSTA transmits a TF Ranging LMR to solicit the I2R LMR frame(s). This TF shall allocate uplink resources to ISTAs that negotiated I2R LMR and were allocated resources in the preceding measurement sounding phase. The RSTA shall allocate each RU in the TF Ranging LMR to only one ISTA. In response to the TF Ranging LMR, each addressed ISTA shall respond by transmitting an I2R LMR frame.

If an ISTA negotiated delayed I2R LMR reporting, and if the TOA measurement for the previous availability window is not ready, then the ISTA shall not respond to the TF Ranging Poll frame in the Polling phase of any availability window until the I2R LMR is ready.

For delayed reporting, the first instance of the R2I LMR and the optional I2R LMR do not have valid TOA/ TOD timestamps to include, in this case the RSTA and the ISTA shall set the Invalid Measurement subfield in the TOA Error field of the respective LMR to 1.

In TB ranging, the PHY shall issue the PHY-RXEND.indication primitive with error condition IntegrityCheckError if the PHY detects the integrity check error in the reception of the corresponding HE Ranging NDP or HE TB Ranging NDP. If the PHY of an RSTA issues a PHY-RXEND.indication primitive with error condition IntegrityCheckError, the RSTA shall set the Invalid Measurement field in the R2I LMR frame carrying the TOA measured from the I2R NDP to 1. Correspondingly, if I2R LMR was negotiated between the ISTA and RSTA and the PHY of the ISTA issues a PHY-RXEND.indication primitive with error condition IntegrityCheckError, the ISTA shall set the Invalid Measurement field in the I2R LMR carrying the TOA measured from the R2I NDP to 1.

NOTE 2—When a STA detects that the transmit center frequency offset (CFO) between the ISTA and the RSTA exceeds the allowed tolerance from the values specified in 27.3.21.3 and 27.3.15.3, this can be an indication of a security attack.

If I2R LMR reporting was negotiated, then the ISTA shall include a CFO parameter in the I2R LMR; see 9.6.7.49. The ISTA shall estimate the CFO parameter based on the PPDU carrying the TF Ranging Sounding frame that solicits the I2R NDP from the ISTA. The RSTA may account for clock rate differences between ISTA and RSTA based on the CFO parameter included in the received I2R LMR. The mechanism by which t4 and t1 are adjusted by the RSTA is implementation specific. The CFO parameter refers to the t1 and t4 indicated in the same I2R LMR.

If the Invalid Measurement field in an R2I LMR or I2R LMR is equal to 1, the RSTA or ISTA receiving the LMR should discard the TOA carried in the LMR.

In TB ranging measurement reporting phase, if R2I LMR reporting or I2R LMR reporting carries phase shift feedback, then the R2I LMR reporting or the I2R LMR reporting shall be immediate feedback.

In TB ranging measurement reporting phase, if R2I AOA feedback was negotiated, the RSTA shall include the optional AOA feedback subfield in the R2I LMR frame and if I2R LMR reporting was negotiated in addition to I2R AOA Feedback reporting then the ISTA shall include the optional AOA feedback subfield in the I2R LMR frame. The AOA field contains the Direction Measurement Results element described in 9.4.2.302.

11.21.6.4.4 Non-TB ranging measurement exchange

11.21.6.4.4.1 General

In Non-TB ranging, the protocol operates in an ISTA centric scheduling FTM mode; whenever the medium is available, an ISTA may initiate the measurement. The RSTA can only limit the frequency with which the ISTA can initiate measurements, by setting a minimum time interval between subsequent range measurements.

The FTM protocol for a non-TB ranging measurement exchange and its relationship with the SME and MLME interface is shown in Figure 11-57 .

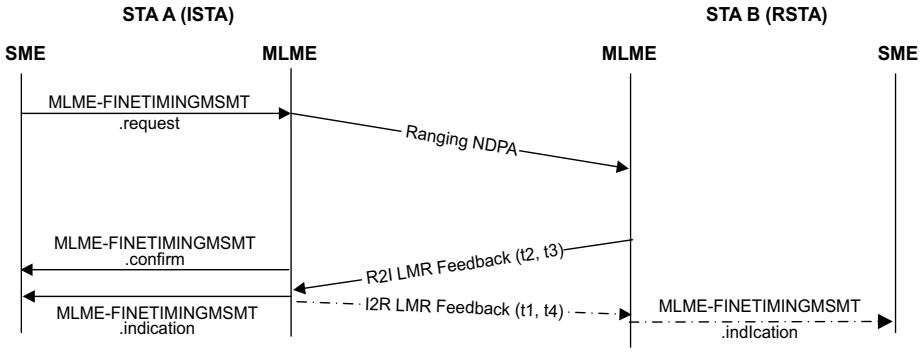

Figure 11-57—FTM primitives and timestamps reporting capture for non-TB ranging measurement exchange

11.21.6.4.4.2 Measurement sounding phase of non-TB ranging

An ISTA shall initiate a non-TB ranging measurement instance by transmitting a Ranging NDP Announcement frame addressed to the RSTA, followed by an I2R NDP SIFS after. In response to the correctly received Ranging NDP Announcement frame addressed to itself, the RSTA shall transmit an R2I NDP; see Figure 11-58 . I2R NDP and R2I NDP refer to NGV Ranging NDPs when dot11NGVOptionImplemented is true and HE ranging NDPs otherwise. The measurement-reporting phase consists of an LMR frame, which is a Location Measurement Report as defined in 9.6.7.49.

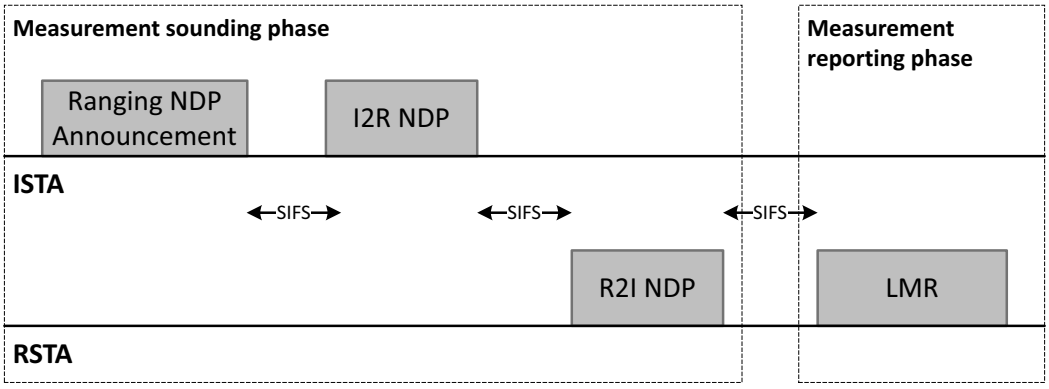

Figure 11-58—Non-TB ranging measurement exchange sequence

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

For immediate feedback the LMR carries measurement results of the current measurement exchange, while for delayed feedback the LMR carries measurement results of the previous measurement exchange; see 11.21.6.4.4.3.

An ISTA shall set the Min Time Between Measurements field and the Max Time Between Measurements field in the Non-TB Specific subelement in the Ranging Parameters element in the IFTMR frame, where Max Time Between Measurements shall be larger than Min Time Between Measurements and takes into account the measurement exchange duration. An RSTA shall assign the value of the Min Time Between Measurements and Max Time Between Measurements in the Non-TB Specific subelement in the Ranging Parameters element in the initial FTM frame, where Max Time Between Measurements shall be larger than Min Time Between Measurements and takes into account of the measurement exchange duration.

An ISTA shall not initiate a new measurement exchange sequence until the assigned minimum time interval between subsequent range measurements has elapsed; see Figure 11-60 . An ISTA should complete the measurement sequence before the assigned maximum time interval between subsequent range measurements has elapsed.

An ISTA may use any AC to transmit the Ranging NDP Announcement frame.

The ISTA maintains a sounding dialog token counter modulo 64 for each FTM session. When transmitting a Ranging NDP announcement frame to an RSTA, the Sounding Dialog Token Number subfield in the Sounding Dialog field shall be set to the value of the corresponding counter; after which the counter shall be incremented by 1.

After transmitting the Ranging NDP Announcement frame and I2R NDP, the ISTA shall wait for a time interval of aSIFSTime + aSlotTime + aRxPHYStartDelay. This interval begins when the MAC receives a PHY-TXEND.confirm primitive for I2R NDP. If a PHY-RXSTART.indication primitive does not occur during the time interval, the ISTA shall conclude that the transmission of the Ranging NDP Announcement frame + I2R NDP has failed and abort the current measurement exchange. If a PHY-RXSTART.indication primitive occurred during the time interval, the ISTA tries to receive the R2I NDP and the LMR frame from the RSTA addressed by the Ranging NDP Announcement frame. If the LMR is received from the RSTA, the frame exchange initiated by the Ranging NDP Announcement frame is complete, otherwise the ISTA shall conclude that the current measurement exchange has failed.

The ISTA may invoke the backoff procedure by an EDCAF when the last frame of the measurement exchange initiated by the Ranging NDP Announcement frame has completed and the TXNAV timer has expired.

In the Non-TB ranging measurement exchange sequence, the ISTA shall transmit the Ranging NDP Announcement frame with the same bandwidth as the I2R NDP to reserve the medium. The Ranging NDP Announcement frame shall be individually addressed with the RA field set to the address of the RSTA, and contain one STA Info field with the AID11 subfield set to 0. If negotiated, the NDP Announcement frame shall contain another STA Info field with AID11 subfield set to 2045, and the I2R Tx Power subfield shall be set to indicate the TX power of the following I2R NDP. If the STA Info field with AID11 subfield set to 2045 is included, the ISTA shall set the R2I NDP Target RSSI subfield to either its preferred receive signal power or a reserved value.

The RSTA shall transmit the R2I NDP with the same bandwidth as the Ranging NDP Announcement frame, while the LMR may be transmitted at a different bandwidth, according to the rules of multiple frame transmission in an EDCA TXOP, see 10.23.2.8. The allowed bandwidths for the Ranging NDP Announcements, I2R NDP, and R2I NDP, shall be less than or equal to the RSTA Assigned Max Bandwidth.

Accordingly:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— An ISTA transmitting an I2R NDP shall set the TXVECTOR parameter CH_BANDWIDTH to the same value as the TXVECTOR parameter CH_BANDWIDTH in the preceding Ranging NDP Announcement frame.
— An RSTA transmitting an R2I NDP shall set the TXVECTOR parameter CH_BANDWIDTH to the bandwidth of the Ranging NDP Announcement frame and/or the I2R NDP; which are obtained from the RXVECTOR parameter CH_BANDWIDTH of the Ranging NDP Announcement frame or I2R NDP, respectively. For the Ranging NDP Announcement frame, when not received in an HE/VHT/HT/NGV PPDU: from the RXVECTOR parameter CH_BANDWIDTH_IN_NON_HT when the Ranging NDP Announcement frame is received in a non-HT duplicate PPDU and is 20 MHz when the Ranging NDP Announcement frame is received in a non-HT PPDU.

If the bandwidth is less than or equal to 80 MHz, the ISTA shall set the I2R NSTS subfield and the R2I NSTS subfield in the STA Info field of the Ranging NDP Announcement frame each to a value not to exceed the *RSTA Assigned I2R STS ≤ 80 MHz* and *RSTA Assigned R2I STS ≤ 80 MHz*, respectively. If the bandwidth is greater than 80 MHz, the ISTA shall set these same subfields to values not to exceed the *RSTA Assigned I2R STS > 80 MHz* and *RSTA Assigned R2I STS > 80 MHz*, respectively.

The ISTA shall set the I2R Rep subfield and R2I Rep subfield in the STA Info field of the Ranging NDP Announcement frame each to a value not to exceed the *RSTA Assigned I2R rep* and *RSTA Assigned R2I rep*, respectively. Furthermore, the total number of LTF in the I2R NDP and R2I NDP, based on the number of spatial streams and repetitions, shall not exceed the *RSTA Assigned I2R LTF Total* and *RSTA Assigned R2I LTF Total*, respectively.

After transmission of the Ranging NDP Announcement frame, the ISTA's MAC sublayer shall issue a PHY-RXLTFSEQUENCE.request primitive with a LTFVECTOR containing the following parameters:

— The SECURE_LTF_FLAG parameter set to 0.
— The LTF_NSTS and LTF_REP parameters set to the same values as indicated, respectively, by the R2I NSTS and R2I Rep subfields in the STA Info field with the AID11 subfield less than or equal to 2007.

After reception of the Ranging NDP Announcement frame, the RSTA's MAC sublayer shall issue a PHY-RXLTFSEQUENCE.request primitive with a LTFVECTOR containing the following parameters:

— The SECURE_LTF_FLAG parameter set to 0.
— The LTF_NSTS and LTF_REP parameters set to the same values as indicated, respectively, by the I2R NSTS and I2R Rep subfields in the STA Info field with the AID11 subfield less than or equal to 2007.

Both RSTA and ISTA perform RTT measurements by capturing the timestamps of the NDP. The ISTA shall record the time at which the I2R NDP is transmitted (t1). The RSTA shall then capture the time at which the I2R NDP arrives (t2) and shall record the time at which the R2I NDP is transmitted (t3). The ISTA shall finally capture the time at which the R2I NDP arrives (t4); see Figure 11-59 . The timestamp values t2 and t3 shall be

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

measured according to the RSTA's clock (i.e., without applying any frequency offset correction to the time basis).

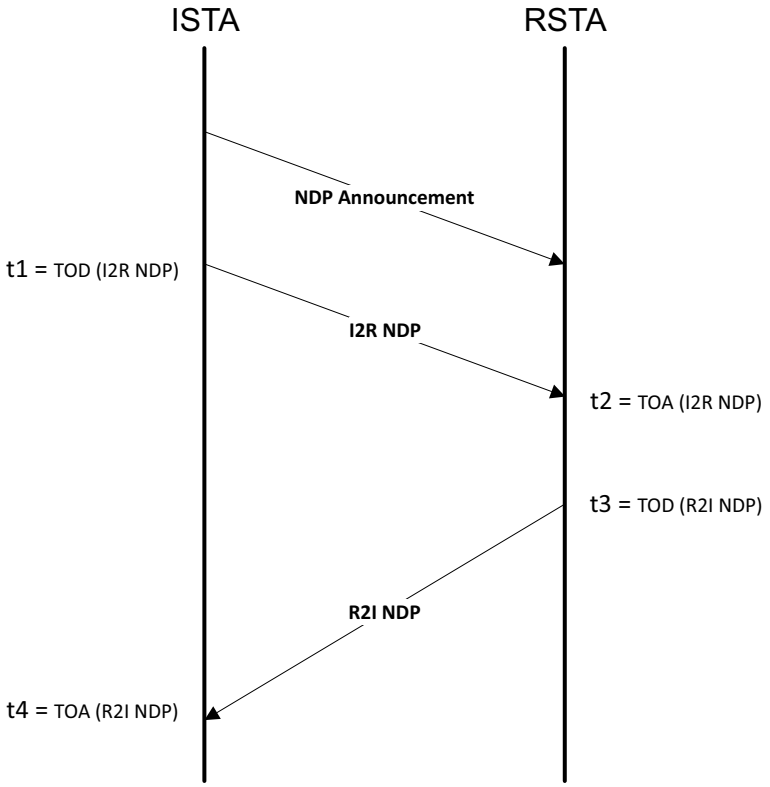

Figure 11-59—Timing diagram of a measurement sounding phase in non-TB ranging

The Round Trip Time (RTT_{ISTA}) based on first path reporting is defined as:

$$RTT_{ISTA} = [(t4 - t1) - (t3' - t2')]$$

where t3' and t2' are the time at which the R2I NDP was transmitted and the time at which the I2R NDP was received, respectively, as converted by the ISTA from the RSTA's time basis to its own time basis.

The mechanism by which the ISTA derives t3' and t2' from the TOD and TOA fields of the relevant LMR is implementation dependent.

The Round Trip Time (RTT_{RSTA}) based on first path reporting is defined as:

$$RTT_{RSTA} = [(t4' - t1') - (t3 - t2)]$$

where t1' and t4' are the time at which the I2R NDP was transmitted and the time at which the R2I NDP was received, respectively, as converted by the RSTA from the ISTA's time basis to its own time basis.

The mechanism by which the RSTA derives t1' and t4' from the TOD and TOA fields of the relevant LMR is implementation dependent.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In an LMR, the TOA field contains a timestamp that represents the time, with respect to a time base, at which the start of the preamble of the corresponding NDP arrived at the receive antenna connector. The TOD field contains a timestamp that represents the time, with respect to the same time base, at which the start of the preamble of the corresponding NDP appeared at the transmit antenna connector.

11.21.6.4.4.3 Non-TB ranging measurement reporting phase

In non-TB ranging, the ranging protocol supports both immediate and delayed reporting.

An RSTA or ISTA indicates immediate reporting by setting the immediate R2I Or I2R Feedback subfield in the Ranging Parameters field of the FTM session frames that enable the measurement exchange, to 1. In immediate reporting, the TOA feedback corresponding to the current measurement exchange sequence shall be reported in the current measurement exchange; see Figure 11-60 .

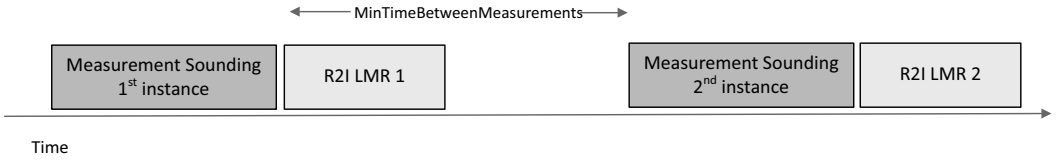

Figure 11-60—Non-TB ranging with immediate reporting

An RSTA or ISTA indicates delayed reporting by setting the Immediate R2I Or I2R Feedback subfield in the Ranging Parameters field to 0. In delayed reporting, the TOA and TOD values in the current LMR shall carry the measurement results of the previous round. In this case, the first instance of the R2I LMR and the optional I2R LMR do not have valid TOA/TOD timestamps to include, and the RSTA and the ISTA shall set the Invalid Measurement subfield in the TOA Error field of the corresponding LMR to 1; see Figure 11-61 .

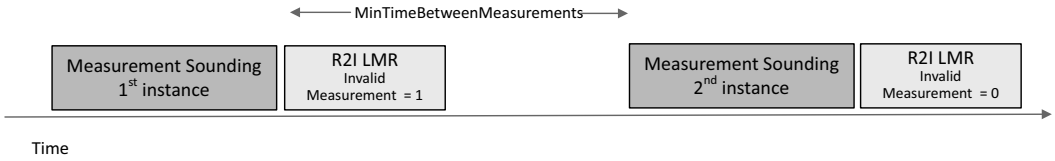

Figure 11-61—Non-TB ranging with delayed reporting

An RSTA that indicated delayed reporting shall provide TOA feedback to the ISTA when the ISTA initiates another measurement sequence after Min Time Between Measurements, but before Max Time Between Measurements; see Figure 11-62 . This TOA feedback is carried in the LMR frame of this new measurement sequence and can be either valid or invalid as indicated by the Invalid Measurement field in the LMR frame.

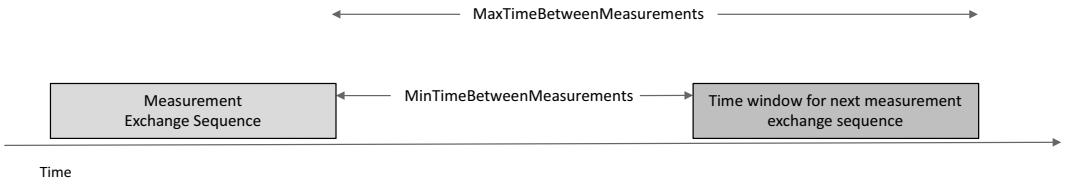

Figure 11-62—Illustration of min time between measurements and max time between measurements with delayed reporting

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The Dialog Token field of the LMR frame shall be copied from the Sounding Dialog Token Number subfield in the Ranging NDP Announcement frame that preceded the NDP which is used for the reported measurement.

If negotiated, the RSTA shall set the R2I TX Power field in the R2I LMR to report the TX power of the preceding R2I NDP; otherwise the R2I Tx Power field shall be set to a reserved value. The RSTA shall set the I2R NDP Target RSSI field to its preferred receive signal power or a reserved value.

If I2R LMR feedback is negotiated, the non-TB ranging measurement exchange (11.21.6.4.4) sequence shall follow the sequence shown in Figure 11-63 . After a SIFS time of receiving the R2I LMR frame, the ISTA shall transmit the I2R LMR frame to the RSTA. The feedback type of I2R LMR could be either immediate or delayed.

NOTE 1—LMR feedback is carried in an Action No-Ack frame and is therefore neither acknowledged nor retransmitted; see 9.6.7.49.

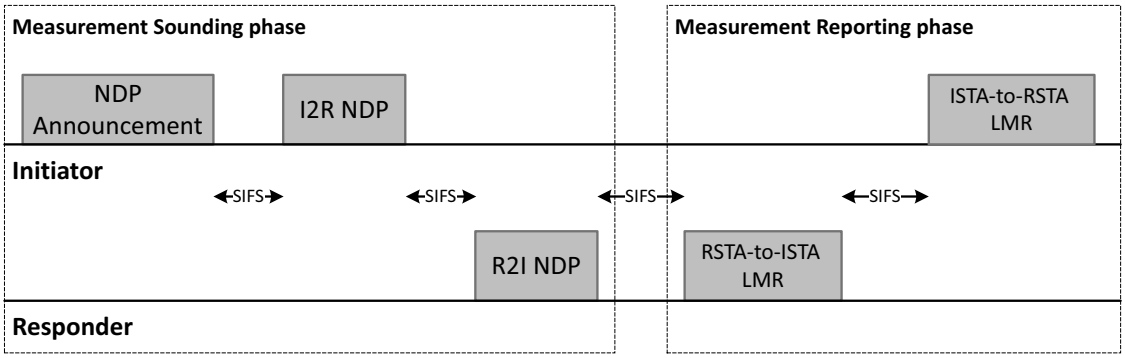

Figure 11-63—Non-TB ranging measurement exchange sequence with bidirectional LMR feedback

The data rate or MCS used for transmitting the R2I and I2R LMR frames is solely decided by the transmitter of each of the frames. The bandwidth used to transmit the R2I LMR frame shall be no greater than that of the soliciting NDP Announcement frame, and the transmit bandwidth of the I2R LMR frame shall be no greater than the bandwidth of the preceding R2I LMR frame.

In non-TB ranging, the PHY shall issue the PHY-RXEND.indication primitive with error condition IntegrityCheckError if the PHY detects the integrity check error in the reception of the corresponding HE Ranging NDP. If the PHY of an RSTA issues a PHY-RXEND.indication primitive with error condition IntegrityCheckError, the RSTA shall set the Invalid Measurement field in the R2I LMR frame carrying the TOA measured from the I2R NDP to 1. Similarly, if I2R LMR was negotiated between the ISTA and RSTA and the PHY of an ISTA issues a PHY-RXEND. Indication primitive with error condition IntegrityCheckError, the ISTA shall set the Invalid Measurement field in the I2R LMR carrying the TOA measured from the R2I NDP to 1.

NOTE 2—When a STA detects that the transmit center frequency offset (CFO) between the ISTA and the RSTA exceeds the allowed tolerance from the values specified in 27.3.21.3 and 27.3.15.3, this can be an indication of a security attack.

In non-TB ranging, both RSTA and ISTA should measure the CFO value based on reception of I2R NDP and R2I NDP, respectively. Therefore, the CFO parameter field in the I2R LMR, if negotiated, and R2I LMR are reserved. The RSTA and ISTA may account for clock rate differences between ISTA and RSTA, respectively, based on their own measured CFO value. The mechanism by which t4 and t1 are adjusted by the RSTA, and t2 and t3 are adjusted by the ISTA is implementation specific.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the Invalid Measurement field in R2I LMR or I2R LMR is equal to 1, the RSTA or ISTA receiving the LMR should discard the TOA carried in the LMR.

In the non-TB ranging measurement reporting phase, if R2I LMR reporting or I2R LMR reporting carries phase shift feedback, then the R2I LMR reporting or the I2R LMR reporting shall be immediate feedback.

In the non-TB ranging measurement reporting phase, if R2I AOA feedback was negotiated the RSTA shall include the optional AOA feedback subfield in the R2I LMR frame and if R2I LMR reporting was negotiated in addition to I2R AOA Feedback reporting then the ISTA shall include the optional AOA feedback subfield (see 9.4.2.302) in the I2R LMR frame. The AOA field contains the Direction Measurement Results element described in 9.4.2.302.

11.21.6.4.5 Secure HE-LTF in the TB and non-TB ranging measurement exchange protocol

11.21.6.4.5.1 General

Both the TB and the non-TB ranging measurement exchanges allow for the use of secure HE-LTF for PHY security if the ISTA and RSTA have established a secure HE-LTF measurement setup as defined in 11.21.6.3.4. The frame exchange sequences stay nominally the same as described in 11.21.6.4.3 and 11.21.6.4.4, except that the HE Ranging NDP and HE TB Ranging NDP use secure HE-LTF as described in 27.3.19.1 and 27.3.19.2, respectively. To use the secure HE-LTF, the ISTA and RSTA need to share and communicate pseudorandom bit sequences that are used to generate and demodulate the secure HE-LTF, the details and management thereof is described in 11.21.6.4.5.2 to 11.21.6.4.5.6.

11.21.6.4.5.2 TB ranging measurement exchange with secure HE-LTF

An example of the negotiation and two TB Ranging Measurement Exchanges with secure HE-LTF is shown in Figure 11-64 , where the LTF_VALID_SAC and SEC_LTF_CTR refer to the values of the Validation SAC and Secure LTF Counter subfields, respectively. The first value of the Validation SAC and its associated Secure LTF Counter subfields shall be included in a protected IFTM frame, and thereafter any subsequent value of the Validation SAC and its corresponding Secure LTF Counter subfield shall be included in a protected R2I LMR frame. The value of the Validation SAC subfield shall also be the same value of the SAC subfield in the Trigger Dependent User Info field of the Secure Sounding Ranging Trigger frame. The description of how these fields are set in the TB ranging measurement exchange is given next.

In a TB ranging measurement exchange with secure HE-LTF where there are multiple ISTAs involved in the measurement sequence, the RSTA shall transmit a Secure Sounding Ranging Trigger frame that includes a single User Info field to trigger a single ISTA at a time.

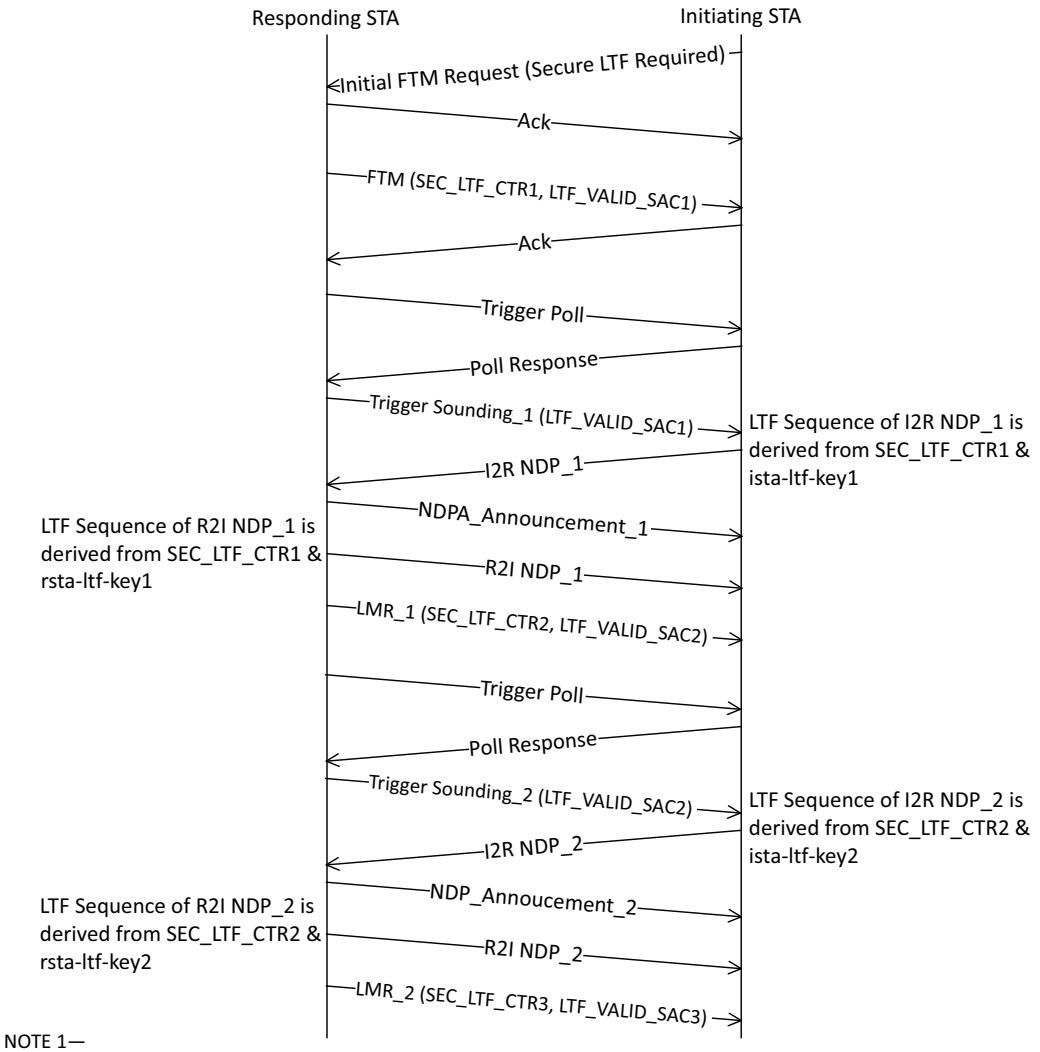
When an RSTA has established a secure HE-LTF measurement exchange with an ISTA as specified in 11.21.6.3.4, the RSTA that sends a Secure Sounding Ranging Trigger frame to the STA shall set:

— The SAC subfield in the Trigger Dependent User Info field corresponding to the ISTA in the Secure Sounding Ranging Trigger frame to the same value as in the Validation SAC field in the Secure HE-LTF Parameters element in the last transmitted protected IFTM, or last transmitted protected LMR frame, to the ISTA.

The RSTA shall set the I2R Rep subfield of the User Info field corresponding to the ISTA in the Secure Sounding Ranging Trigger frame equal to the value of the *RSTA Assigned I2R Rep* corresponding to the ISTA, where the value of the *RSTA Assigned I2R Rep* shall be greater than 0.

After transmission of the Secure Sounding Ranging Trigger frame to the ISTA, the RSTA's MAC sublayer shall issue a PHY-RXLTFSEQUENCE.request primitive with a LTFVECTOR containing the following parameters:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.



NOTE 1—
When LMR_2 is a delayed feedback type, Range Measurement SAC carried in LMR_2 is set to LTF_VALID_SAC1.
When LMR_2 is an immediate feedback type, Range Measurement SAC carried in LMR_2 is set to LTF_VALID_SAC2.

Figure 11-64—Overview of the TB ranging measurement exchange with secure HE-LTF

— The SECURE_LTF_FLAG parameter set to 1.
— The LTF_NSTS and LTF_REP parameters set to the same values, respectively, as indicated by the SS Allocation and I2R Rep subfields of the User Info field.
— The LTF_KEY and LTF_IV parameters that are set to *ista-ltf-key* and *ltf-iv*, respectively, for generating the secure HE-LTF based on the value of the Secure LTF Counter subfield in the Secure HE-LTF Parameters element in the last transmitted protected IFTM frame or last transmitted protected LMR frame to the ISTA; see 11.21.6.4.5.4.
— The TX_WINDOW_FLAG set to 1 if the RSTA and ISTA have negotiated to use the optional frequency domain Tx window for I2R NDP; it is set to 0 otherwise.
— The LTF_OFFSET set to 0.

When the RSTA receives the HE TB Ranging NDP from the ISTA, the RSTA shall:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

a) Send a Ranging NDP Announcement frame.
b) Send an HE Ranging NDP with the TXVECTOR parameters LTF_KEY and LTF_IV set to the *rsta-ltf-key* and *ltf-iv*, respectively, for generating secure HE-LTF based on the value of the Secure HE-LTF Counter subfield in the Secure HE-LTF Parameters element in the last transmitted protected IFTM frame or last transmitted protected LMR frame to the ISTA; see 11.21.6.4.5.4.
c) Send a protected LMR frame that includes the Secure HE-LTF Parameters element to the ISTA.

Otherwise, the RSTA shall follow the rules in 10.23.2.2 as the frame exchange is not successful.

When an RSTA sends a Ranging NDP Announcement frame, it shall set the LTF Offset subfield in the STA Info fields to values that satisfy Equation (11-7) and Equation (11-8).

$$\text{Offset}_i \leq \sum_{k \in \text{MaxOffset}_i} \text{N\_LTF}_k \times \text{Rep}_k \tag{11-7}$$

$$\text{Offset}_i \geq \text{Offset}_j + \text{N\_LTF}_j \times \text{Rep}_j, \quad \forall\, j \in \text{MinOffset}_i \tag{11-8}$$
$$\text{If Offset}_i = 0 \text{ then N\_STS}_i \geq \text{N\_STS}_j, \quad \forall\, j$$

where

Offset_n represents the LTF Offset subfield value of the *n*th STA Info field in the Ranging NDP Announcement frame.
N_STS_n represents the R2I NSTS subfield value plus 1 of the *n*th STA Info field in the Ranging NDP Announcement frame.
N_LTF_n represents the number of HE-LTF symbols based on N_STS_n, see Table 21-13, for the *n*th STA Info field in the Ranging NDP Announcement frame.
Rep_n represents the R2I Rep subfield value plus 1 of the *n*th STA Info field in the Ranging NDP Announcement frame.
MinOffset represents the set of indexes of the STA Info fields of which the LTF Offset subfield values are less than the LTF Offset subfield value of the *i*th STA Info field in the Ranging NDP Announcement frame.
MaxOffset represents the set of indexes of all STA Info fields excluding the *i*th STA Info field.

The RSTA shall set the R2I Rep subfield in each of the STA Info fields in the Ranging NDP Announcement frame equal to the *RSTA Assigned R2I Rep* for each of the corresponding ISTAs, where all of the *RSTA Assigned R2I Rep* shall be greater than 0.

When an ISTA receives a Secure Sounding Ranging Trigger frame from an RSTA in which the value of the SAC subfield in the Trigger Dependent User Info field is equal to the value of the Validation SAC subfield in the Secure HE-LTF Parameters element in the last protected IFTM frame, or last protected LMR frame, received from the RSTA, the ISTA shall send an HE TB Ranging NDP with the TXVECTOR parameters LTF_KEY and LTF_IV that are set to *ista-ltf-key* and *ltf-iv*, respectively, for generating the secure HE-LTF based on the value of the Secure LTF Counter subfield in the Secure HE-LTF Parameters element in the last protected IFTM frame, or last protected LMR frame, received from the RSTA; see 11.21.6.4.5.4.

When an ISTA receives a Secure Sounding Ranging Trigger frame from an RSTA in which the value of the SAC subfield in the Trigger Dependent User Info field is not equal to the value of the Validation SAC subfield in the Secure HE-LTF Parameters element in the last protected IFTM frame or last protected LMR frame received from the RSTA, the ISTA shall send an HE TB Ranging NDP with the TXVECTOR parameters LTF_KEY and LTF_IV that are set to the *ista-ltf-key* and *ltf-iv*, respectively, for generating any secure HE-LTF.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When an ISTA receives a Ranging NDP Announcement frame from an RSTA in which the AID11 subfield in the STA Info field contains the 11 least significant bits of the AID or RSID of the ISTA, the ISTA shall issue a PHY-RXLTFSEQUENCE.request primitive with the following LTFVECTOR parameters:

— The SECURE_LTF_FLAG parameter set to 1.
— The LTF_NSTS, LTF_REP, and LTF_OFFSET parameters set to the same values, respectively, as indicated by the R2I NSTS, R2I Rep, and LTF Offset subfields of the STA Info field addressed to it.
— The LTF_KEY and LTF_IV parameters that are set to the *rsta-ltf-key* and *ltf-iv* for generating the secure HE-LTF based on the value of the Secure LTF Counter subfield in the Secure LTF Parameters element in the last protected IFTM frame, or last protected LMR frame received from the RSTA; see 11.21.6.4.5.4.
— The TX_WINDOW_FLAG set to 1 if the ISTA and RSTA have negotiated to use the optional frequency domain Tx window for R2I NDP; it is set to 0 otherwise.

When an LMR frame contains range measurement results measured from an I2R NDP or an R2I NDP, an RSTA that transmits an R2I LMR frame, or when negotiated, an ISTA that transmits an I2R LMR frame, shall include the Secure HE-LTF Parameters element in the protected LMR frame:

— The Measurement SAC subfield in the Secure HE-LTF Parameters element in the protected LMR frame shall be set to the same value as in the SAC subfield in the Trigger Dependent User Info field in the Secure Sounding Ranging Trigger destined to the ISTA receiving or transmitting this protected LMR frame.
— The Measurement Result LTF Offset subfield in the Secure HE-LTF Parameters element in the protected LMR frame shall be set to the same value as in the LTF Offset subfield of the STA Info field in the Ranging NDP Announcement frame that preceded the R2I NDP destined to the ISTA for this measurement result.

When an ISTA or RSTA receives the R2I or I2R protected LMR frame, the ISTA or RSTA shall compare the value of the Measurement Result LTF Offset subfield with the value of the LTF Offset subfield in the corresponding STA Info field of the Ranging NDP Announcement frame, and if these two values don’t match, the ISTA or RSTA shall discard the measurement results carried in the protected LMR frame.

When a frame exchange that consists of receiving an HE TB Ranging NDP and transmitting HE Ranging NDP results into a Null-SAC-HE-LTF, the RSTA shall not use the TOA and TOD value of the HE TB Ranging NDP and HE Ranging NDP, respectively, and shall set the Invalid Measurement Indication subfield to 1 in the TOA error field in the protected LMR carrying the TOA value of the I2R HE TB Ranging NDP.

When an ISTA receives a Secure Sounding Ranging Trigger frame from an RSTA in which the value of the SAC subfield in the Trigger Dependent User Info field is not equal to the value of the Validation SAC subfield in the Secure HE-LTF Parameters element in the last protected IFTM frame or last protected LMR frame received from the RSTA, the ISTA shall:

— Not use the TOD value of the I2R HE TB Ranging NDP.
— Not use the TOA value of the R2I HE Ranging NDP, and shall set the Invalid Measurement Indication subfield to 1 in the TOA Error field in the protected LMR carrying the TOA value of the HE Ranging NDP if the I2R LMR transmission from the ISTA was negotiated.

The STA shall use a new SAC value and its corresponding ista-ltf-key and rsta-ltf-key in every ranging measurement exchange, even if the current ranging measurement exchange is unsuccessful.

NOTE—In TB ranging measurement exchange with secure HE-LTF, the RSTA never sends the SAC subfield with value 0 in the Trigger Dependent User Info field in the Secure Sounding Ranging Trigger frame.

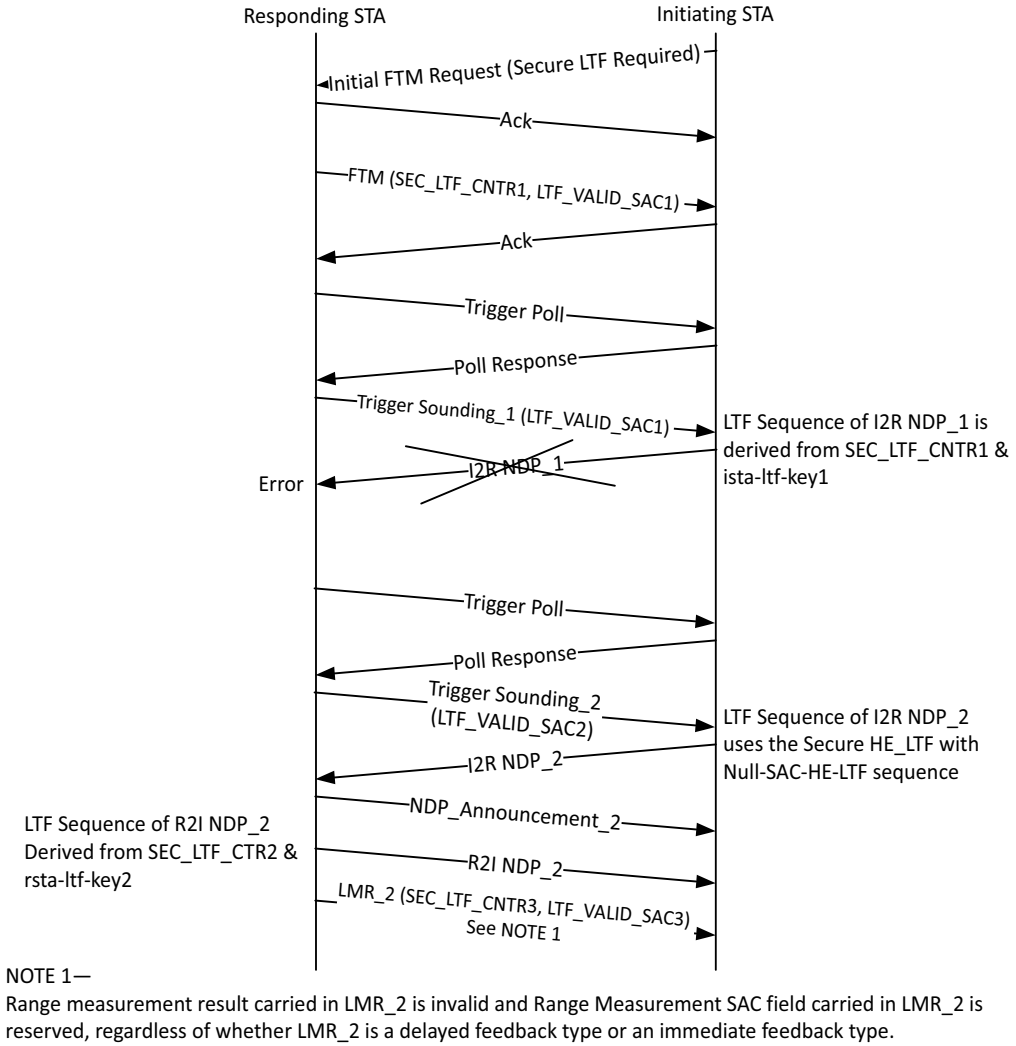
When there is a transmission failure within a secure measurement exchange sequence, the recovery procedure of the LTF_VALID_SAC and its associated SEC_LTF_CTR parameters is illustrated in Figure 11-65 .



NOTE 1—
Range measurement result carried in LMR_2 is invalid and Range Measurement SAC field carried in LMR_2 is reserved, regardless of whether LMR_2 is a delayed feedback type or an immediate feedback type.

Figure 11-65—Error recovery of TB ranging measurement exchange using secure HE-LTF

11.21.6.4.5.3 Non-TB ranging measurement exchange with secure HE-LTF

An overview of the negotiation and two non-TB ranging measurement exchanges are illustrated in Figure 11-66 . The LTF_VALID_SAC and its associated SEC_LTF_CTR parameter shall be included in a protected IFTM frame and a protected R2I LMR frame. The LTF_VALID_SAC shall also be included in the SAC subfield in the Ranging NDP Announcement frame. The detailed description of how the fields in these frames are set follows.

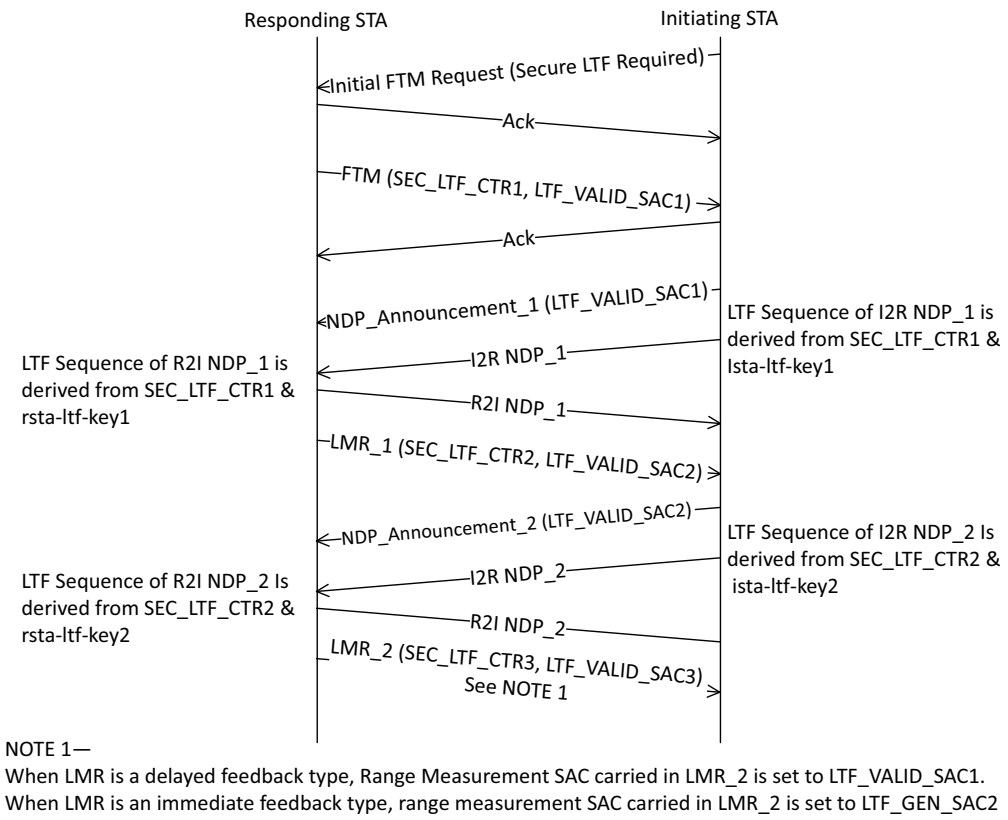
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.



NOTE 1—
When LMR is a delayed feedback type, Range Measurement SAC carried in LMR_2 is set to LTF_VALID_SAC1.
When LMR is an immediate feedback type, range measurement SAC carried in LMR_2 is set to LTF_GEN_SAC2

Figure 11-66—Overview of the non-TB ranging measurement exchange with secure HE-LTF

When an ISTA has established a secure HE-LTF measurement exchange with an RSTA as specified in 11.21.6.3.4, this ISTA shall set the following subfields in any Ranging NDP Announcement frame addressed to that RSTA as follows:

— The SAC subfield in the STA Info field with AID11 equal to 2043 in the Ranging NDP Announcement frame is set to the same value contained in the Validation SAC subfield in the Secure HE-LTF Parameters element in the last protected IFTM frame, or last protected R2I LMR frame, received from the RSTA.

— Otherwise the SAC subfield in the STA Info field with AID11 equal to 2043 in the Ranging NDP Announcement frame is set to a value of 0 to indicate that a new SEC_LTF_CTR and the corresponding LTF_VALID_SAC parameter are needed.

The ISTA shall set the I2R Rep subfield and R2I Rep subfield of the STA Info field in the Ranging NDP Announcement frame to the values of *RSTA Assigned I2R Rep* and the *RSTA Assigned R2I Rep*, respectively, corresponding to the RSTA. Both values of the *RSTA Assigned R2I Rep* and *RSTA Assigned I2R Rep* shall be greater than 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An ISTA that sends an I2R NDP a SIFS after transmission of the Ranging NDP Announcement frame shall set the TXVECTOR parameters LTF_KEY and LTF_IV as follows:

— Either to the value of Null-SAC-HE-LTF if the SAC subfield in the STA Info field with AID11 equal to 2043 in the Ranging NDP Announcement frame, is equal to 0.

— Or the *ista-ltf-key* and *ltf-iv* for generating secure HE-LTF based on the value of the Secure LTF Counter subfield in the Secure HE-LTF Parameters element in the last protected IFTM frame or last protected LMR frame, received from the RSTA; see 11.21.6.4.5.4.

After transmission of the Ranging NDP Announcement frame to the RSTA, the ISTA's MAC sublayer shall issue a PHY-RXLTFSEQUENCE.request primitive with an LTFVECTOR containing the following parameters:

— The SECURE_LTF_FLAG parameter set to 1.

— The LTF_NSTS and LTF_REP parameters set to the same values as indicated, respectively, by the R2I NSTS and R2I Rep subfields in the STA Info field with the AID11 subfield less than or equal to 2007.

— The LTF_KEY and LTF_IV parameters that are set to either the value of Null-SAC-HE-LTF, if the SAC subfield in the STA Info field with AID11 equal to 2043 in the Ranging NDP Announcement frame is equal to 0; or the *rsta-ltf-key* and *ltf-iv* for generating a secure HE-LTF based on the values of the Secure LTF Counter subfield in the Secure HE-LTF Parameters element in the last protected IFTM frame, or last protected LMR frame received, from the RSTA; see 11.21.6.4.5.4.

— The TX_WINDOW_FLAG set to 1 if the ISTA and RSTA have negotiated to use the optional frequency domain Tx window for R2I NDP; it is set to 0 otherwise.

— The LTF_OFFSET set to 0.

When an RSTA receives a Ranging NDP Announcement frame from an ISTA in which the SAC subfield in the STA Info field with AID11 equal to 2043 is not equal to the value of the Validation SAC subfield in the Secure HE-LTF Parameters element in the last transmitted protected IFTM frame or last transmitted protected LMR frame to the ISTA, the RSTA shall:

— Send an HE Ranging NDP to the ISTA with the TXVECTOR parameters *rsta-ltf-key* and *ltf-iv* for generating any secure HE-LTF to the ISTA, only if the RSTA receives an HE Ranging NDP from the ISTA a SIFS after the ranging NDP Announcement frame.

— Send a protected LMR frame with a Secure HE-LTF Parameters element containing the SEC_LTF_CTR and the corresponding LTF_VALID_SAC parameters to the ISTA, only if the RSTA receives an HE Ranging NDP from the ISTA a SIFS after the ranging NDP Announcement frame.

When an RSTA receives a Ranging NDP Announcement frame from an ISTA in which the value of the SAC subfield in the STA Info field with AID11 equal to 2043 is equal to the value of the Validation SAC subfield in the Secure HE-LTF Parameters element in the last transmitted protected IFTM frame or last transmitted protected LMR frame to the ISTA, the RSTA shall:

— Send an HE Ranging NDP with the TXVECTOR parameters *rsta-ltf-key* and *ltf-iv* for generating a secure HE-LTF based on the values of the Secure LTF Counter in the Secure HE-LTF Parameters element in the last transmitted protected IFTM frame, or last transmitted protected LMR frame to the ISTA, only if the RSTA receives an HE Ranging NDP from the ISTA a SIFS after the ranging NDP Announcement frame; see 11.21.6.4.5.4.

— Send a protected LMR frame that includes the Secure HE-LTF Parameters element to the ISTA, only if the RSTA receives an HE Ranging NDP from the ISTA a SIFS after the ranging NDP Announcement frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When an RSTA receives a Ranging NDP Announcement frame from an ISTA, the RSTA shall also issue a PHY-RXLTFSEQUENCE.request primitive with an LTFVECTOR with the following parameters:

— The SECURE_LTF_FLAG parameter set to 1.
— The LTF_NSTS and LTF_REP parameters set to the same values as indicated, respectively, by the I2R NSTS and I2R Rep subfields in the STA Info field with the AID11 subfield less than or equal to 2007.
— The LTF_KEY and LTF_IV parameters that are set to the *ista-ltf-key* and *ltf-iv* for receiving a secure HE-LTF based on the values of the Secure LTF Counter and corresponding Validation SAC subfields in the Secure LTF Parameters element in the last transmitted protected IFTM frame, or last transmitted protected LMR frame to the ISTA; see 11.21.6.4.5.4.
— The TX_WINDOW_FLAG set to 1 if the ISTA and RSTA have negotiated to use the optional frequency domain Tx window for I2R NDP; it is set to 0 otherwise.
— The LTF_OFFSET set to 0.

An RSTA transmitting an R2I LMR frame, or an ISTA when negotiated to transmit LMR frame, containing range measurement results measured from an I2R NDP and an R2I NDP, shall include the Secure HE-LTF Parameters element in the protected LMR frame and set the Measurement SAC subfield in the Secure HE-LTF Parameters element in the protected LMR frame to the same value as in the SAC subfield in the STA Info field with AID11 equal to 2043 in the Ranging NDP Announcement frame that solicited the I2R NDP and the R2I NDP.

When a STA sends a Null-SAC-HE-LTF in a HE Ranging NDP, the STA shall not use the TOD value of the HE Ranging NDP for the secure range measurement exchange.

When a STA receives a Null-SAC-HE-LTF in a HE Ranging NDP, the STA shall not use the TOA value of the HE Ranging NDP, and shall set the Invalid Measurement Indication subfield to 1 in the TOA Error field in the protected LMR carrying the TOA value of the HE Ranging NDP.

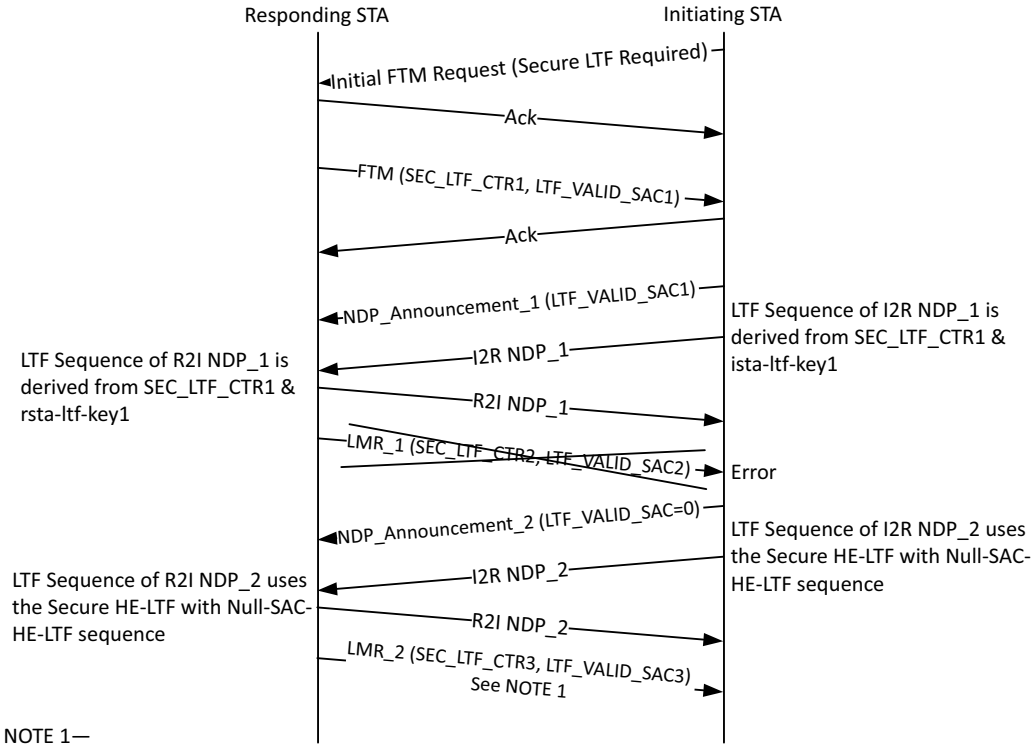
When there is a transmission failure within a secure measurement exchange, the recovery procedure of the LTF_VALID_SAC is illustrated in Figure 11-67 .



NOTE 1—
When LMR is a delayed feedback type, Range Measurement SAC carried in LMR_2 is set to LTF_VALID_SAC1. When LMR is an immediate feedback type, range measurement result carried in LMR_2 is invalid and Range Measurement SAC field carried in LMR_2 is reserved.

Figure 11-67—Error recovery of non-TB ranging measurement exchange using secure HE-LTF

A STA shall discard the LTF_VALID_SAC parameter used in the frame exchange and shall not use the same LTF_VALID_SAC parameter in the current measurement exchange.

11.21.6.4.5.4 Overview of secure HE-LTF octet stream generation

This subclause describes mechanisms for generating the SAC, LTF protection keys, counters, and the pseudorandom octet stream used to randomize the input to the modulation and per stream phase rotation for constructing secure HE-LTFs. The mechanism is illustrated in Figure 11-68 and Figure 11-69 .

For each secure measurement (e.g., NDP exchanges), a SAC and two secret keys *ista-ltf-key* and *rsta-ltf-key* shall be derived by the ISTA and the RSTA independently as follows:

SAC-and-LTF-Keys = KDF-Hash-Length(Secure-LTF-Key-Seed, “Secure LTF Expansion”, Secure-LTF-Counter)

where

KDF and Hash	are the key derivation function and hash function determined by the AKM used to derive the PTKSA from which the Secure-LTF-Key-Seed was derived
Length	is equal to 272 (bits)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

SAC	is equal to ExtractBits(SAC-and-LTF-Keys, 0, 16)
ista-ltf-key	is equal to ExtractBits(SAC-and-LTF-Keys, 16, 128)
rsta-ltf-key	is equal to ExtractBits(SAC-and-LTF-Keys, 144, 128)

The *ista-ltf-key* shall be used to generate the pseudorandom octet stream to protect all of the LTFs in PPDUs transmitted by the ISTA. The *rsta-ltf-key* shall be used to generate the pseudorandom octet stream to protect all of the LTFs in PPDUs transmitted by the RSTA. The ISTA and RSTA shall use the same derivation and derive identical keys.

With the SAC constructed as above, an attacker not knowing the Secure-LTF-Key-Seed would not be able to predict the SAC that would be used for a given measurement.

Integer to octet string conversion (MSB first) specified in 12.4.7.2.2 shall be used to encode the value of the Secure LTF Counter subfield in the KDF as well as in the transmitted LTF sequence information. The counter shall be padded with leading (MSB) 0s to be exactly 6 octets.

The 16-octet IV input *ltf-iv* to the secure HE-LTF bit generator shall be constructed as follows:

— First 6 octets shall be the transmitter MAC address (A2).
— Next 6 octets shall encode the value of the Secure LTF Counter subfield with the encoding convention described above.
— Final 4 octets shall be used as a 32-bit block counter. The block counter shall be initialized to 0 before the NDP with secure HE-LTFs is transmitted or received. The counter shall be incremented by 1 each time an AES block is output by the generator.

Each time pseudorandom bits are required to protect the LTFs in an NDP, the secure HE-LTF bit generator generates the required number of AES blocks using the AES algorithm (see FIPS 197) with the corresponding 128-bit key and 128-bit IV inputs. The output of the AES-128 counter encryption is a 128-bit integer. It shall be converted using the conventions specified in 12.4.7.2.2 to obtain the octet stream used for secure HE-LTF generation.

NOTE 1—A 6-octet parameter representing the value of the Secure LTF Counter subfield is sufficient because a protected individually addressed Management frame that uses a 6-octet PN is used to convey the LTF sequence information that carries the counter.

NOTE 2—The pseudorandom bit generator is based on AES-128 Counter mode approved by NIST (see NIST SP 800-90A R1 [B66]).

The number of pseudorandom bits that can be generated without violating security guarantees of the scheme is 2^{39} without updating the key or reseeding the generator with additional entropy.

Secure HE-LTF measurement requires a variable number of octets from the pseudorandom octet stream depending on the TXVECTOR or RXVECTOR parameters for the LTFs as described in 27.3.20.2. The initial block counter value used to construct the *ltf-iv* for setting the TXVECTOR and RXVECTOR parameters shall be 0.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.21.6.4.5.5 Secure HE-LTF octet stream generation on an ISTA

Figure 11-68 illustrates the scheme for generating the SAC, LTF protection keys, and counter values used to generate a pseudorandom octet stream on an ISTA.

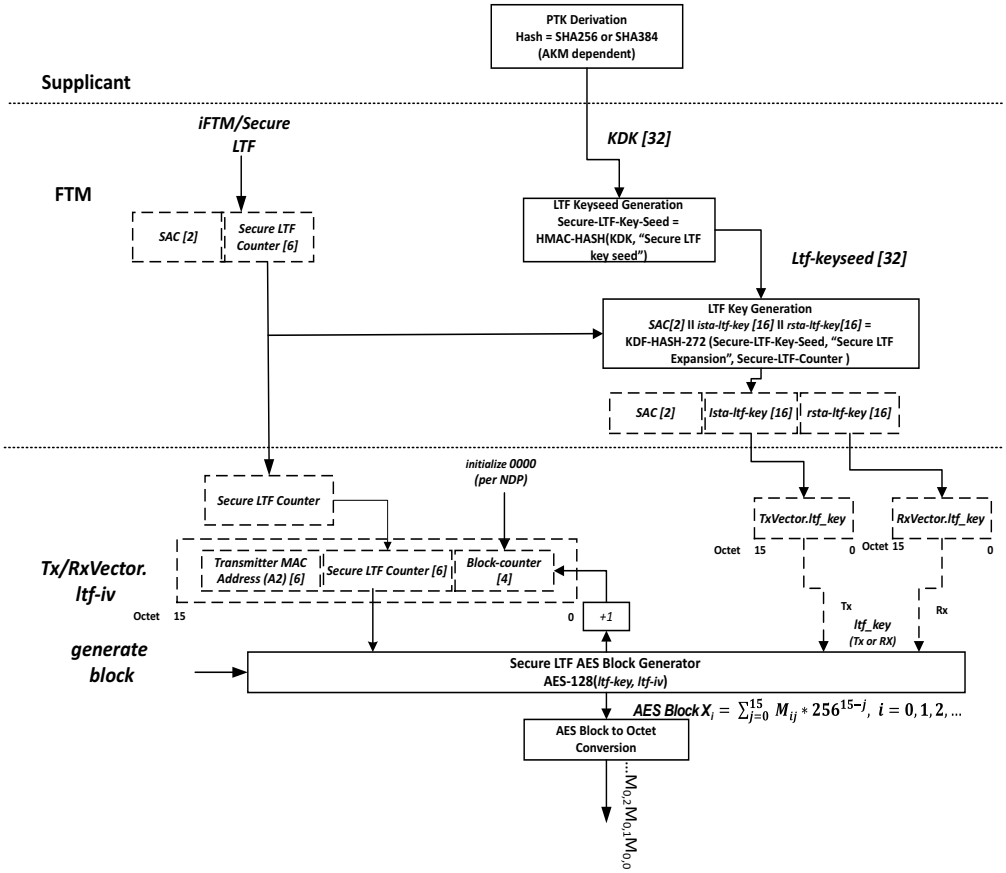

Figure 11-68—ISTA secure HE-LTF octet stream generation

For each secure measurement on an ISTA, the following parameters shall be used for generating the pseudorandom octet stream used to construct the LTFs for NDPs:

— The *ista-ltf-key* and *rsta-ltf-key* for transmitted NDP (TXVECTOR parameter LTF_KEY) and received NDP (RXVECTOR parameter LTF_KEY), respectively.

— The *ltf_iv* for transmitted NDP (TXVECTOR parameter LTF-IV) and received NDP (RXVECTOR parameter LTF-IV) with corresponding ISTA MAC address and RSTA MAC address, respectively, together with the value of the Secure LTF Counter subfield and the block counter.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.21.6.4.5.6 Secure HE-LTF input octet stream generation on an RSTA

Figure 11-69 illustrates the scheme for generating the SAC, LTF protection keys, and counter values used to generate a pseudorandom octet stream on an RSTA.

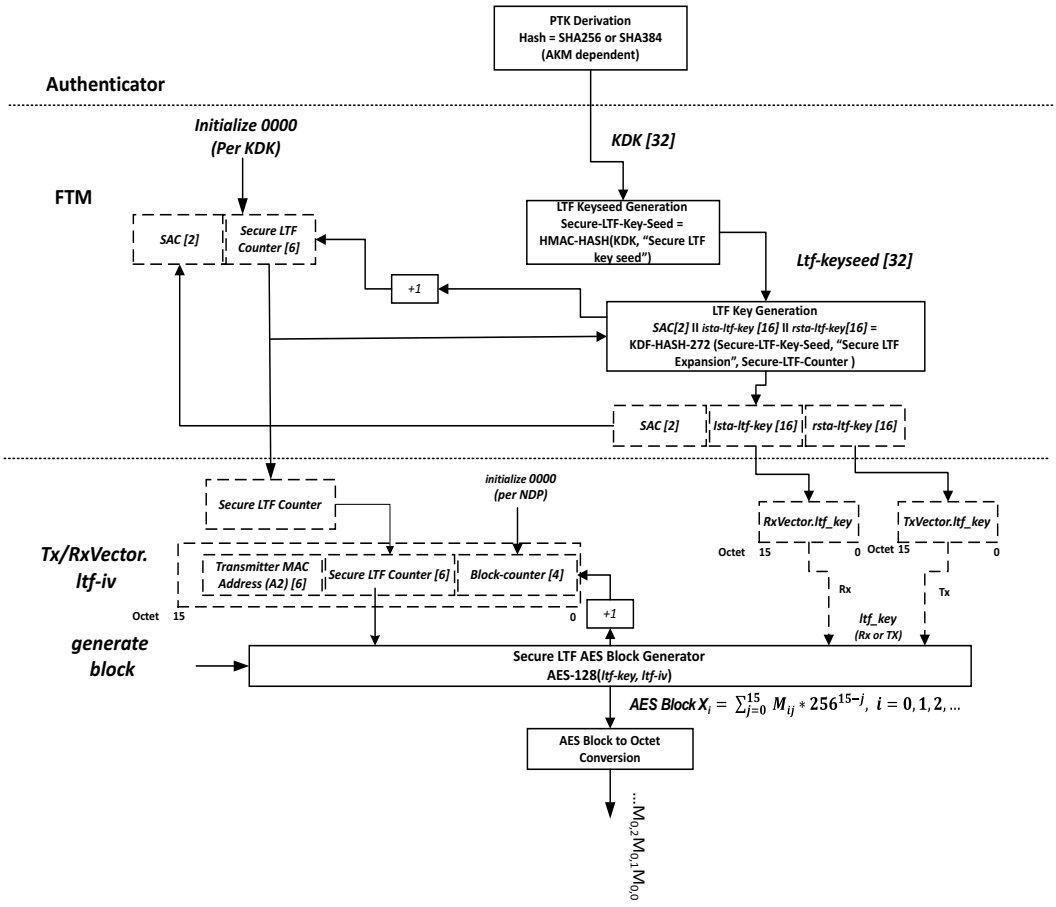

Figure 11-69—RSTA secure HE-LTF octet stream generation

For each secure measurement on an RSTA, the following parameters are provided for generating the pseudorandom octet stream to construct the LTFs for NDPs:

— The *ista-ltf-key* and *rsta-ltf-key* for received NDP (RXVECTOR parameter LTF_KEY) and transmitted NDP (TXVECTOR parameter LTF_KEY), respectively.

— The *ltf_iv* for received NDP (RXVECTOR parameter LTF-IV) and for transmitted NDP (TXVECTOR parameter LTF-IV) with corresponding ISTA MAC address and RSTA MAC address, respectively, together with the values of the Secure LTF Counter subfield and the block counter.

NOTE—In an R2I NDP used for range measurement, LTFs assigned to each of the recipient STAs would use their corresponding pseudorandom octet stream derived from the key material from the corresponding PTKSA for the recipient.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The values of the Secure LTF Counter subfield shall be maintained for the lifetime of a PTKSA used for secure HE-LTF measurements. It shall not be reset between measurements and shall not be reset for multiple FTM negotiations using the same PTKSA.

The values of the Secure LTF Counter subfield used for each measurement protected bits is derived from a given Secure-LTF-Key-Seed (and its KDK and the PTKSA) and shall be unique. When the derived SAC is equal to 0, the RSTA shall increment the secure LTF counter parameter by 1 and derive the SAC until a nonzero SAC value is obtained. An RSTA shall also increment the secure LTF counter parameter by 1 each time an *ista-ltf-key* and *rsta-ltf-key* are derived.

11.21.6.4.6 Transmission of a ranging NDP

An RSTA transmitting an HE Ranging NDP to one or more peer ISTAs shall set the TXVECTOR parameters as follows:

- The FORMAT parameter is set to HE_SU.
- The RANGING_FLAG is present.
- The UPLINK_FLAG parameter is set to 0.
- The APEP_LENGTH parameter is set to 0.
- The SECURE_LTF_FLAG is set as follows:
  - Is set to 0 in the TB ranging measurement exchange (11.21.6.4.3) and non-TB ranging measurement exchange (11.21.6.4.4).
  - Is set to 1 in the TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.2) and the non-TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.3).
- The TX_WINDOW_FLAG is set to 1 if the SECURE_LTF_FLAG is set to 1 and the RSTA and ISTA have negotiated to use the optional frequency domain Tx window for R2I NDPs; it is set to 0 otherwise.
- In the TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.2), the NUM_USERS parameter is set to the number of ISTAs to which the HE Ranging NDP is transmitted.
- In the Non-TB ranging measurement exchange (11.21.6.4.4), the TXPWR_LEVEL_INDEX parameter is set to a value that matches the Tx Power value indicated in the R2I NDP Tx Power field in the following LMR frame, except if the value in the R2I NDP Tx Power field was set to a reserved value.
- The DOPPLER parameter is set to 0.
- The NUM_STS parameter is set as follows:
  - In the TB ranging measurement exchange (11.21.6.4.3), set to the same value as the R2I NSTS subfield in the STA Info field in the preceding Ranging NDP Announcement frame plus 1.
  - In the TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.2):
    - When the HE Ranging NDP is transmitted to more than one ISTA, the NUM_STS[p] parameter is set to the same value as the R2I NSTS subfield in the STA Info field addressed to the corresponding STA p in the preceding Ranging NDP Announcement frame plus 1.
    - When the HE Ranging NDP is transmitted to one ISTA, the NUM_STS parameter is set to the same value as the R2I NSTS subfield in the STA Info field with AID11 subfield equal or less than 2007 in the preceding Ranging NDP Announcement frame plus 1.
  - In the Non-TB ranging measurement exchange (11.21.6.4.4) and the non-TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.3), set to the same value as the R2I NSTS subfield in the STA Info field with AID11 subfield equal or less than 2007 in the preceding Ranging NDP Announcement frame plus 1.
- The LTF_REP parameter is set as follows:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

- In the TB ranging measurement exchange (11.21.6.4.3), set to the same value as the R2I Rep subfield in the STA Info field in the preceding Ranging NDP Announcement frame plus 1.
- In the TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.2):
  - When the HE Ranging NDP is transmitted to more than one ISTA, the LTF_REP[*p*] parameter is set to the same value as the R2I Rep subfield in the STA Info field addressed to the corresponding STA *p* in the preceding Ranging NDP Announcement frame plus 1.
  - When the HE Ranging NDP is transmitted to one ISTA, the LTF_REP parameter is set to the same value as the R2I Rep subfield in the STA Info field with AID11 subfield equal or less than 2007 in the preceding Ranging NDP Announcement frame plus 1.
- In the non-TB ranging measurement exchange (11.21.6.4.4) and the non-TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.3), set to the same value as the R2I Rep subfield in the STA Info field with AID11 subfield less than or equal to 2007 in the preceding Ranging NDP Announcement frame plus 1.

— The CH_BANDWIDTH parameter is set as follows:
  - In the TB ranging measurement exchange (11.21.6.4.3), and TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.2), set to the same value as the TXVECTOR parameter CH_BANDWIDTH in the preceding Ranging Sounding Trigger frame.
  - In the non-TB ranging measurement exchange (11.21.6.4.4) and non-TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.3), set to the same value as the TXVECTOR parameter CH_BANDWIDTH in the preceding Ranging NDP Announcement frame.
— In the TB and non-TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5), the LTF_KEY parameter is set as defined in 11.21.6.4.5.2 and 11.21.6.4.5.3. Otherwise, the LTF_KEY parameter is not present.
— In the TB ranging measurement exchange with secure HE-LTF, the LTF_OFFSET parameter is set as defined in 11.21.6.4.5.2. Otherwise, the LTF_OFFSET parameter is not present.
— The HE_LTF_TYPE parameter is set to 2xHE-LTF.
— The GI_TYPE parameter is set to 1u6s_GI.
— The SPATIAL_REUSE parameter is set to PRS_AND_NON-SRG_OBSS-PD_PROHIBITED.
— The BSS_COLOR parameter is set to the value indicated in the BSS Color subfield of the HE Operation element transmitted by the RSTA.
— The TXOP_DURATION parameter is set to either 127 or a value defined in Equation (26-3), replacing $D_{\text{HE\_NDPA}}$ by $D_{\text{Ranging\_NDPA}}$, which is the value of the Duration/ID field in the MAC header of the preceding Ranging NDP Announcement frame.

An ISTA transmitting an HE Ranging NDP shall set the TXVECTOR parameters as follows:

— The FORMAT parameter is set to HE_SU.
— The RANGING_FLAG is present.
— The UPLINK_FLAG parameter is set to 1.
— The APEP_LENGTH parameter is set to 0.
— The SECURE_LTF_FLAG is set as follows:
  - Is set to 0 in the non-TB ranging measurement exchange (11.21.6.4.4).
  - Is set to 1 in the non-TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.3).
— The TX_WINDOW_FLAG is set to 1 if the SECURE_LTF_FLAG is set to 1 and the RSTA and ISTA have negotiated to use the optional frequency domain Tx window for I2R NDPs; it is set to 0 otherwise.
— The DOPPLER parameter is set to 0.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The NUM_STS parameter is set to the same value as the I2R NSTS subfield in the STA Info field with AID11 subfield equal or less than 2007 in the preceding Ranging NDP Announcement frame plus 1.
— The LTF_REP parameter is set to the same value as the I2R Rep subfield with AID11 subfield equal or less than 2007 in the STA Info field in the preceding Ranging NDP Announcement frame plus 1.
— The TXPWR_LEVEL_INDEX parameter is set to a value that matches the Tx Power value indicated in the I2R NDP Tx Power subfield in the STA Info field with the AID11 subfield set to 2045 in the preceding Ranging NDP Announcement frame, except if the value in the I2R NDP Tx Power subfield was set to a reserved value.
— The CH_BANDWIDTH is set to the same value as the TXVECTOR parameter CH_BANDWIDTH in the preceding Ranging NDP Announcement frame.
— In the non-TB ranging measurement exchange with secure HE-LTF, the LTF_KEY parameter is set as defined in 11.21.6.4.5.3. Otherwise, the LTF_KEY parameter is not present.
— The HE_LTF_TYPE parameter is set to 2xHE-LTF.
— The GI_TYPE parameter is set to 1u6s_GI .
— The SPATIAL_REUSE parameter is set to PRS_AND_NON-SRG_OBSS-PD_PROHIBITED.
— The BSS_COLOR parameter is set to the value indicated in the BSS Color subfield of the HE Operation element received from the RSTA.
— The TXOP_DURATION parameter is set to either 127 or a value defined in Equation (26-3), replacing $D_{\text{HE\_NDPA}}$ by $D_{\text{Ranging\_NDPA}}$, which is the value of the Duration/ID field in the MAC header of the preceding Ranging NDP Announcement frame.

An ISTA transmitting an HE TB Ranging NDP to an RSTA shall set the TXVECTOR parameters as follows:

— The FORMAT parameter is set to HE_TB.
— The RANGING_FLAG is present.
— The APEP_LENGTH parameter is set to 0.
— The SECURE_LTF_FLAG is set as follows:
  — Is set to 0 in the TB ranging measurement exchange (11.21.6.4.3).
  — Is set to 1 in the TB ranging measurement exchange with secure HE-LTF (11.21.6.4.5.2).
— The TX_WINDOW_FLAG is set to 1 if the SECURE_LTF_FLAG is set to 1 and the RSTA and ISTA have negotiated to use the optional frequency domain Tx window for I2R NDPs; it is set to 0 otherwise.
— The DOPPLER parameter is set to 0.
— The NUM_STS parameter is set to the same value as the Number Of Spatial Streams subfield in the SS Allocation field in the User Info field in the preceding Ranging Sounding Trigger frame.
— The LTF_REP parameter is set to the same value as the I2R Rep subfield in the User Info field in the preceding Ranging Sounding Trigger frame plus 1.
— The CH_BANDWIDTH parameter is set to the same value as the TXVECTOR parameter CH_BANDWIDTH in the preceding Ranging Sounding Trigger frame.
— In the TB ranging measurement exchange with secure HE-LTF, the LTF_KEY parameter is set as defined in 11.21.6.4.5.2. Otherwise, the LTF_KEY parameter is not present.
— The HE_LTF_TYPE parameter is set to 2xHE-LTF.
— The GI_TYPE parameter is set to 1u6s_GI.
— The SPATIAL_REUSE parameter is set to SRP_AND_NON-SRG_OBSS_PD_PROHIBITED.
— The BSS_COLOR parameter is set to the value indicated in the BSS Color subfield of the HE Operation element received from the RSTA.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The TXOP_DURATION parameter is set as defined in 26.11.5.

An RSTA transmitting an NGV ranging NDP to an ISTA shall set the TXVECTOR parameters as follows:

— The FORMAT parameter is set to NGV.
— The CH_BANDWIDTH parameter is set to the same value as the RXVECTOR parameter CH_BANDWIDTH in the preceding I2R NDP.
— The NGV-LTF-TYPE parameter is set to 1 to indicate NGV_LTF_2X is used in the NGV ranging NDP.
— The NUM_SS parameter is set to the same value as the R2I N_STS in the STA Info field in the preceding Ranging NDP Announcement frame.
— The APEP_LENGTH parameter is set to 0.
— The LTF_REP parameter is set to the same value as the R2I LTF_REP in the STA Info field in the preceding Ranging NDP Announcement frame.

An ISTA transmitting an NGV ranging NDP to an RSTA shall set the TXVECTOR parameters as follows:

— The FORMAT parameter is set to NGV.
— The CH_BANDWIDTH parameter is set to the same value as the TXVECTOR parameter CH_BANDWIDTH in the preceding Ranging NDP Announcement frame.
— The NGV-LTF-TYPE parameter is set to 1 to indicate NGV_LTF_2X is used in the NGV ranging NDP.
— The NUM_SS parameter is set to the same value as the I2R N_STS in the STA Info field in the preceding Ranging NDP Announcement frame.
— The APEP_LENGTH parameter is set to 0.
— The LTF_REP parameter is set to the same value as the I2R LTF_REP in the STA Info field in the preceding Ranging NDP Announcement frame.

11.21.6.4.7 Time of arrival estimation using phase shift feedback

Based on Figure 11-70 , and Equation (11-9), to enable the ISTA to derive the RTT, the RSTA needs to compute TOA t2 and feed t2 and t3 back to the ISTA using R2I LMR. Instead of utilizing TOA t2 for RTT computation, a phase shift feedback can be prepared by the RSTA and fed back to the ISTA for deriving RTT.

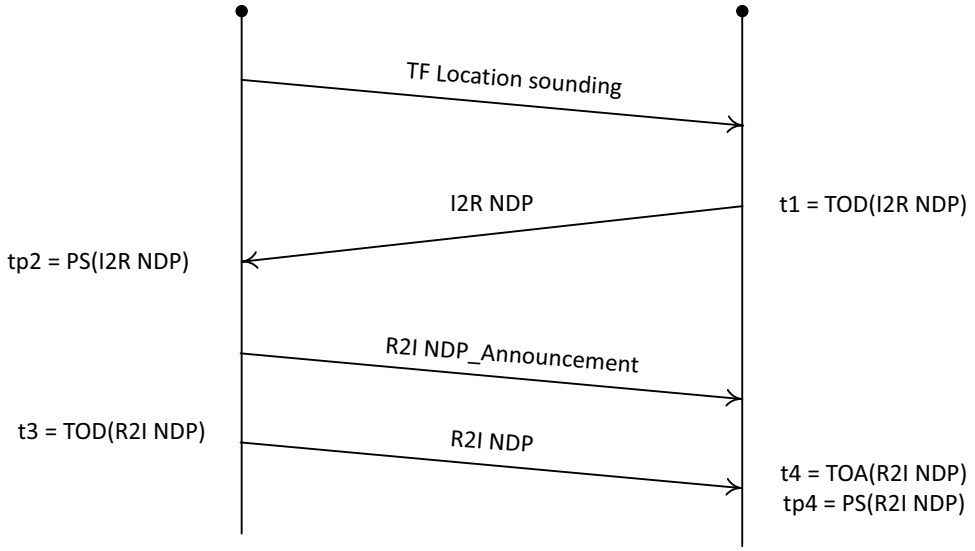

Figure 11-70—Timing diagram of a measurement sounding phase in TB ranging based on phase shift of I2R NDP and R2I NDP PPDUs

As shown in Figure 11-70 , in the phase shift feedback method, the ISTA transmits an I2R NDP at TOD t1, and the RSTA determines the phase shift tp2 of the I2R NDP. The RSTA transmits an R2I NDP at TOD t3, and the ISTA determines the phase shift tp4 and TOA t4 of the R2I NDP. tp2 and tp4 are determined from the phase slope of the frequency domain channel estimation of the corresponding NDP. An example of calculation of the phase shift is shown in Annex AD.

The RSTA sends the R2I NDP at TOD t3, and after receiving the R2I NDP, the ISTA calculates the phase shift tp4 and TOA t4 of R2I NDP. The value of tp2 and tp4 are calculated utilizing the frequency domain channel estimation of I2R NDP and R2I NDP.

The phase shift is defined as the average linear phase shift between two adjacent tones normalized by the tone spacing. To enable the ISTA to calculate the RTT, the RSTA should feed phase shift tp2 and TOD t3 back to the ISTA using R2I LMR, and the ISTA can calculate the RTT according to Equation (11-9).

$$RTT_{ISTA} = (t4 - t1) - (t3 - t2''), \text{ with } t2'' = tp2 - (tp4 - t4) \quad (11\text{-}9)$$

When the I2R LMR with phase shift feedback is negotiated between ISTA and RSTA, I2R LMR carries phase shift tp4 and TOD t1, and then the RSTA can calculate the RTT according to Equation (11-10).

$$RTT_{RSTA} = (t4'' - t1) - (t3 - t2), \text{ with } t4'' = tp4 - (tp2 - t2) \quad (11\text{-}10)$$

11.21.6.4.8 Measurement exchange in passive TB ranging mode

11.21.6.4.8.1 General

As stated in 11.21.6.1.3, the passive TB ranging mode is a variant of the TB ranging mode. In all aspects, except where explicitly stated differently, the passive TB ranging mode, its protocols, procedures, components, and definitions follow the rules for TB ranging mode.

In particular, the measurement exchanges for passive TB ranging follow the rules and procedures described in 11.21.6.4.3, with subclauses, unless explicitly stated otherwise.

In passive TB ranging, the RSTA shall transmit the Passive Sounding Ranging Trigger frame instead of the Sounding Ranging Trigger frame. Upon receiving of the Passive Sounding Ranging Trigger frame, the ISTA shall respond with an HE Ranging NDP instead of an HE TB Ranging NDP; see 11.21.6.4.8.3 for further details.

Furthermore, the RSTA shall broadcast two frames, the Primary and Secondary RSTA Broadcast Passive TB Ranging Measurement Report frames containing measurement data and related information; see 11.21.6.4.8.4 for further details.

The passive TB ranging exchanges shall only occur in an availability window assigned for Passive TB ranging.

For passive TB ranging, the timestamps reported within each availability window shall be derived from a clock that runs continuously during the availability window.

If there is a discontinuity in the clock for the FTM timestamping between two reported TOD timestamps, then the TOD Not Continuous subfield in the Timestamp Error subfield of the Timestamp Measurement Report subfield in the ISTA Passive TB Ranging Measurement Report element shall be set to 1. Otherwise it shall be set to 0.

The FTM protocol for a passive TB ranging measurement exchange and its relationship with the SME and MLME interface is shown in Figure 0-1 (FTM primitives and timestamps reporting capture for passive TB ranging measurement exchange).

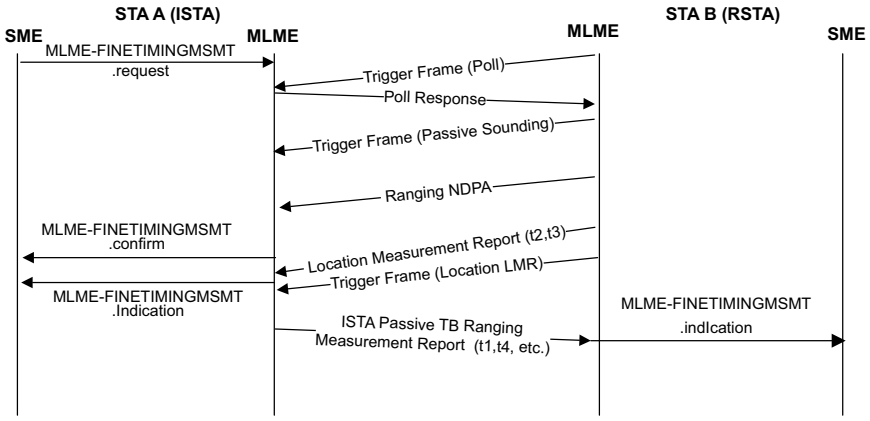

Figure 11-71—FTM primitives and timestamps reporting capture for passive TB ranging measurement exhange

11.21.6.4.8.2 Polling phase of passive TB ranging

The Polling phase of passive TB ranging follows the same rules and procedures for the Polling phase of TB ranging described in 11.21.6.4.3.2.

11.21.6.4.8.3 Passive TB ranging measurement sounding phase

The passive TB ranging measurement sounding follows the same rules and procedures for the measurement sounding for TB ranging described in 11.21.6.4.3.3, unless explicitly stated otherwise.

The second phase of the passive TB ranging measurement sequence, after the passive TB ranging polling phase, is called the passive TB ranging measurement sounding phase. The passive TB ranging measurement sounding phase may include one or more Passive Sounding Ranging Trigger frames and HE Ranging NDP exchanges, a Ranging NDP Announcement frame, and an HE Ranging NDP transmission; see Figure 11-72 .

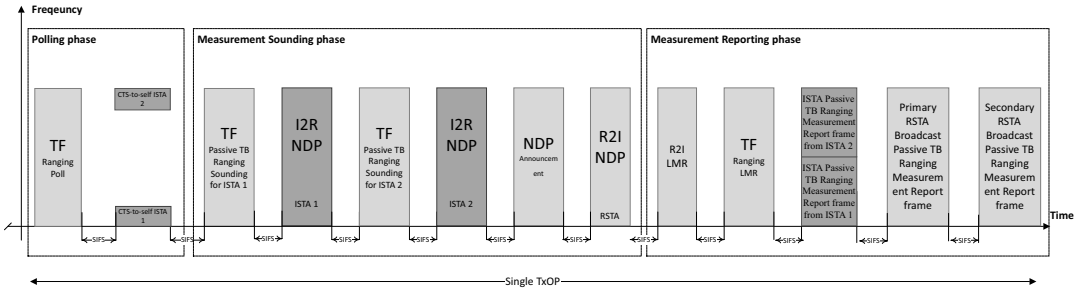

Figure 11-72—Passive TB ranging polling, measurement sounding, and measurement reporting phases

In passive TB ranging, for each ISTA, the RSTA shall transmit a Passive Sounding Ranging Trigger frame, which includes a single User Info field.

An RSTA shall transmit one or more Passive Sounding Ranging Trigger frames, each of which is addressed to a single ISTA, the first one coming a SIFS time after the TB Polling phase.

An ISTA addressed by the AID/RSID in the Passive Sounding Ranging Trigger frame shall transmit an HE Ranging NDP a SIFS time after the reception of the Passive TB Ranging Trigger frame.

An RSTA transmitting a Passive Sounding Ranging Trigger frame shall not use a bandwidth wider than that indicated in the IFTM frame sent to the ISTA, and the RSTA shall set the TXVECTOR parameter CH_BANDWIDTH to be the same value as the UL BW subfield of the Common Info field in the Passive Sounding Ranging Trigger frame.

NOTE—Generally a PSTA benefits from consistent ranging measurement performance when an RSTA initiates a passive TB ranging sequence with the nominal advertised bandwidth in every TXOP.

An RSTA transmitting a Ranging NDP Announcement frame and an HE Ranging NDP after receiving an HE Ranging NDP as a response to a Passive Sounding Ranging Trigger frame shall set the TXVECTOR parameter CH_BANDWIDTH to be the same value as the BW subfield of the Common Info field in the Passive Sounding Ranging Trigger frame.

An ISTA transmitting an HE Ranging NDP as a response to a Passive Sounding Ranging Trigger frame shall set the TXVECTOR parameter CH_BANDWIDTH to be the same value as the UL BW subfield of the Common Info field in the Passive Sounding Ranging Trigger frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

As in TB ranging, an ISTA participating in a passive TB ranging exchange shall measure the TOD of its own HE Ranging NDP and either the TOAs, or both the TOAs and the phase shift feedback TOAs (PSTOAs), when it receives the RSTA's HE Ranging NDP. In addition, optionally the ISTA may also measure and report either the TOAs, or both the TOAs and the PSTOAs, when it receives the HE Ranging NDPs transmitted by the other ISTAs participating in the passive TB ranging exchange. By reporting the timestamps for when it received the other ISTAs NDP transmissions, the quality of the location estimate for a PSTA listening in to the passive TB ranging exchanges can be improved.

The value of NSTS used in the passive TB ranging exchanges shall be less than or equal to 4.

When phase shift feedback is negotiated between an ISTA and an RSTA in passive TB ranging, the protocol for the Measurement Sounding phase differs from passive TB ranging with TOA feedback on the following points:

- The RSTA shall measure phase shift feedback TOA (PSTOA), in addition to measuring the TOA, on the I2R NDP it receives from the ISTA.
- The ISTA shall measure:
  - The phase shift TOA (PSTOA), in addition to measuring the TOA, for the R2I NDP it receives from the RSTA,
  - And may also measure phase shift TOA(s) (PSTOAs), in addition to measuring the TOA(s), for the I2R NDP(s) it receives from other ISTA(s).

See Figure 11-73 for an example of timestamps measured by the RSTA, ISTA, and a PSTA in a passive TB ranging measurement exchange. The timestamp values t1, t2, t3, and t4 are analogous to the corresponding labeled timestamps in 11.21.6.4.3.3. The timestamps t5 and t6 are the times at which the I2R NDP and R2I NDPs arrive at the PSTA, respectively.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

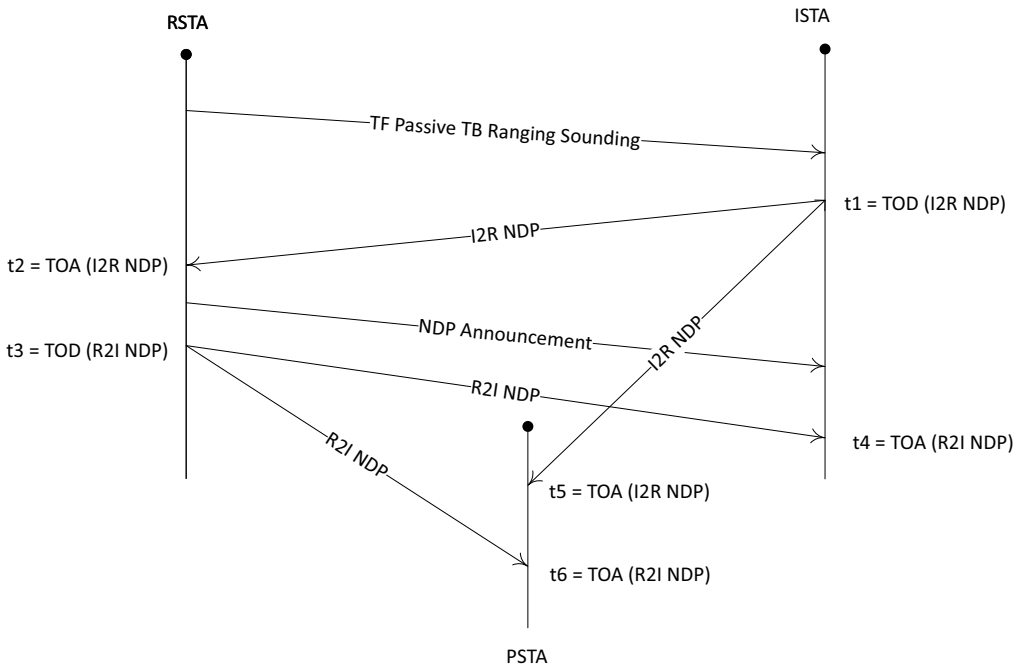

Figure 11-73—Example timing diagram of a Measurement Sounding phase in passive TB ranging

The PSTA may use the ISTA's and RSTA's timestamps, together with its own measured TOAs of the ranging NDPs, t5 and t6, to calculate its differential time of flight to the RSTA and the ISTA.

The differential time-of-flight (DToF) from PSTA to RSTA and ISTA (DToF_PRI) is defined by Equation (11-11).

$$\text{DToF\_PRI} = \text{ToF\_PR} - \text{ToF\_PI} \tag{11-11}$$

where

ToF_PR is the time of flight between the PSTA and the RSTA
ToF_PI is the time of flight between the PSTA and the ISTA

The differential time of flight DToF_PRI can be computed as per Equation (11-12):

$$\text{DToF\_PRI} = t6 - t5 - 0.5 \times t3' + 0.5 \times t2' - 0.5 \times t4' + 0.5 \times t1' \tag{11-12}$$

where

t1' and t4' are the time at which the I2R NDP was transmitted from the ISTA and the time at which the R2I NDP was received by the ISTA, respectively, converted by the PSTA from the ISTA's time basis to the PSTA's time basis.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

t2' and t3' are the time at which the I2R NDP was received by the RSTA and the time at which the R2I NDP was transmitted by the RSTA, respectively, converted by the PSTA from the RSTA's time basis to the PSTA's time basis.

At the PSTA, the mechanism by which t1' and t4' is derived from t1, t4, the ISTA's reported CFO, and the PSTA's CFO measured with respect to the RSTA, is implementation dependent.

At the PSTA, the mechanism by which t2' and t3' is derived from t2, t3, and the PSTA's CFO measured with respect to the RSTA, is implementation dependent.

By multiplying the differential time of flight, DToF_PRI, with the speed of light, the differential distance from PSTA to RSTA and ISTA can be computed.

See 11.21.6.4.9 for how the PSTA's differential distance to the RSTA and the ISTA can be computed using PSTOAs measured by the RSTA and the ISTA.

11.21.6.4.8.4 Passive TB ranging Measurement Reporting phase

The passive TB ranging measurement reporting follows the same rules and procedures for the measurement reporting for TB ranging described in 11.21.6.4.3.4, unless explicitly stated otherwise.

The last phase of the passive TB ranging measurement sequence is the passive TB ranging Measurement Reporting phase and occurs a SIFS time after the passive TB ranging Measurement Sounding phase; see Figure 11-74 for a depiction of the passive TB ranging Measurement Reporting phase.

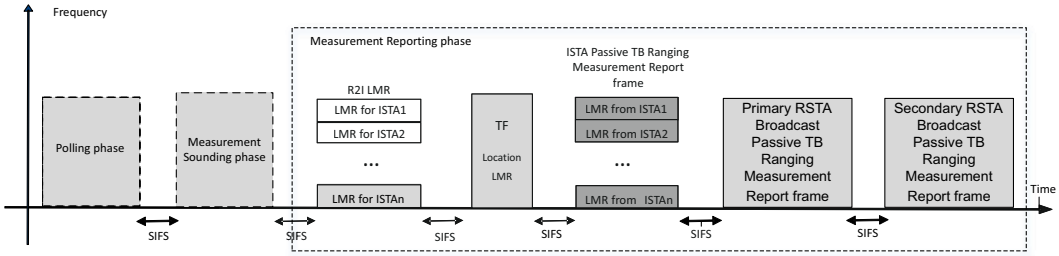

Figure 11-74—Passive TB ranging Measurement Reporting phase

In the passive TB ranging Measurement Reporting phase, an RSTA shall send a Passive TB Ranging Measurement Report frame and the Report Ranging Trigger frame to one or more ISTAs that sent an HE Ranging NDP in the preceding passive TB ranging Measurement Sounding phase. An ISTA addressed by the Report Ranging Trigger frame shall transmit an ISTA Passive TB Ranging Measurement Report frame a SIFS time after the Report Ranging Trigger frame transmission to report its I2R LMR.

In order to facilitate broadcasting of the ISTA's timestamps by the RSTA, the ISTA Passive TB Ranging Measurement Report frame shall be transmitted as a public Action frame.

The ISTA Passive TB Ranging Measurement Report element, see 9.4.2.306, in ISTA Passive TB Ranging Measurement Report frames shall contain:

— A Sounding Dialog Token Number identifying the measurement sounding phase in which the reported ISTA's timestamps were measured.
— The CFO of the ISTA with respect to the RSTA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The TOD timestamp for the I2R NDP that the ISTA transmitted—labeled with the AID12/RSID12 of the ISTA.
— The TOA timestamp for the R2I NDP that the ISTA received from the RSTA.
— Optionally, the TOA timestamps for the I2R NDPs received from other ISTAs participating in the passive TB ranging (i.e., polling, sounding, and reporting triplet) identified by the Sounding Dialog Token Number—labeled with their respective AID12/RSID12s.

If phase shift TOA reporting has been negotiated, the ISTA Passive TB Ranging Measurement Report element shall also include:

— The PS-TOA timestamp of the R2I NDP that the ISTA received from the RSTA.
— Optionally, the PS-TOAs for the I2R NDPs received from other ISTAs participating in the passive TB ranging (i.e., polling, sounding, and reporting triplet) identified by the Sounding Dialog Token Number—labeled with their respective AID12/RSID12s.

The ISTA Passive TB Ranging Measurement Report frame shall include an entry for the ISTA's I2R NDP TOD.

The ISTA shall set the More subfield in the More & N Timestamp Measurements Report field in the ISTA Passive TB Ranging Measurement Report element contained in the ISTA Passive TB Ranging Measurement Report frame to 1 if it has more timestamps ready to report but does not have space in its allocated resources by the RSTA for ISTA Passive TB Ranging Measurement Report frame. Else the ISTA shall set the More subfield to 0.

The RSTA shall send the Primary and Secondary RSTA Broadcast Passive TB Ranging Measurement Report frames, the Primary a SIFS time after receiving the ISTA Passive TB Ranging Measurement Report frames from the ISTA and the Secondary a SIFS following the Primary; see Figure 11-74 .

The Primary RSTA Broadcast Passive TB Ranging Measurement Report frame shall contain the following:

— Passive TB Ranging LCI Table Counter.
— Passive TB Ranging LCI Table Countdown Info.
— RSTA Passive TB Ranging Measurement Report.
— Passive TB Ranging LCI Table (optionally present).

Each time an RSTA transmits a Primary RSTA Broadcast Passive TB Ranging Measurement Report frame, it shall set the Passive TB Ranging LCI Table Counter value such as to refer to the latest version of the Passive TB Ranging LCI Table element transmitted by the RSTA.

If a Passive TB Ranging LCI Table element is included in the Primary RSTA Broadcast Passive TB Ranging Measurement Report frame, and this element has different content as compared to the last transmitted Passive TB Ranging LCI Table element, then the Passive TB Ranging LCI Table Counter shall be incremented by 1 (modulo 256) from the value associated with the previous Passive TB Ranging LCI Table element content. (The first time the RSTA transmits a Passive TB Ranging LCI Table element the value shall be set to 0). This new value of the Passive TB Ranging LCI Table Counter is now associated with this new version of the Passive TB Ranging LCI Table element.

If a Passive TB Ranging LCI Table element is included in the Primary RSTA Broadcast Passive TB Ranging Measurement Report frame, and this element has the same content as the last transmitted Passive TB Ranging LCI Table element, then the Passive TB Ranging LCI Table Counter value shall be the value associated with this last version of the Passive TB Ranging LCI Table element transmitted by the RSTA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If a Passive TB Ranging LCI Table element is not included in the Primary RSTA Broadcast Passive TB Ranging Measurement Report frame, then the Passive TB Ranging LCI Table Counter value shall be the value associated with the last version of the Passive TB Ranging LCI Table element transmitted by the RSTA.

When the Passive TB Ranging LCI Table is present in the Primary Broadcast Passive TB Ranging Measurement Report frame, the RSTA LCI Report field of the Passive TB Ranging LCI Table Report element shall contain the Antenna Placement And Calibration subelement if the RSTA has dot11PassiveTBRangingAODImplemented equal to true, and shall not contain the Antenna Placement And Calibration subelement if the RSTA has dot11PassiveTBRangingAODImplemented equal to false.

When the Passive TB Ranging LCI Table is present in the Primary Broadcast Passive TB Ranging Measurement Report frame, the corresponding entry of the ISTA LCI Reports Entries field of the Passive TB Ranging LCI Table Report element shall contain the Antenna Placement And Calibration subelement if the ISTA has dot11PassiveTBRangingAoDImplemented equal to true, and shall not contain the Antenna Placement And Calibration subelement if the ISTA has dot11PassiveTBRangingAODImplemented equal to false.

The Secondary RSTA Broadcast Passive TB Ranging Measurement Report frame shall contain the following:

— ISTA Passive TB Ranging Measurement Reports.

See 9.6.7.52.

When phase shift feedback is negotiated between an ISTA and an RSTA in Passive TB ranging, the protocol for the measurement reporting phase differs from Passive TB ranging with TOA feedback on the following points:

— The RSTA shall report its measured PSTOA in the R2I LMR frame.
— The ISTA shall report its measured PSTOA(s), in addition to its measured TOA(s), in the ISTA Passive TB Ranging Measurement Report frame.
    — The PSTOAs are indicated as phase shift TOA timestamps by setting the Measurement Report field of the ISTA Passive TB Ranging Measurement Report element, see 9.4.2.306, to the value 10 (PSTOA).
— In the Primary RSTA Broadcast Passive TB Ranging Measurement Report frame, the RSTA shall send a broadcast frame containing its measured PSTOA, in addition to its measured TOA, for the I2R NDPs it has received from the ISTA.
— In the Secondary RSTA Broadcast Passive TB Ranging Measurement Report frame the RSTA shall rebroadcast the timestamps the ISTA has reported to the RSTA. As the ISTA has negotiated phase shift feedback, these would contain PSTOAs in addition to TOAs.

When phase shift feedback is negotiated in Passive TB ranging, the reporting by both the RSTA and the ISTA of phase shift TOAs, the TOD, and CFO shall be immediate feedback. The reported TOAs may be immediate or delayed feedback. When the TOA feedback is delayed, the dialog token shall refer to the previous measurement instance for the RSTA–ISTA pair.

The TODs and PSTOAs measured by the RSTA shall be broadcast in the Primary RSTA Broadcast Passive TB Ranging Measurement Report frame in the reporting phase following the measurement exchange in which they were measured.

The CFO, TOD, and PSTOAs reported by the ISTA shall be rebroadcasted in the Secondary RSTA Broadcast Passive TB Ranging Measurement Report frame in the reporting phase following the measurement exchange in which they were measured.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.21.6.4.9 Passive TB ranging differential time-of-flight calculations using phase shift TOA timestamps

In Figure 11-75 , passive TB ranging measurement exchanges and their reception by a passive station, a PSTA, are depicted for the case when the RSTA and the ISTA are measuring and reporting phase shift TOAs, PSTOAs; see Annex AD for how the phase shift TOAs are calculated.

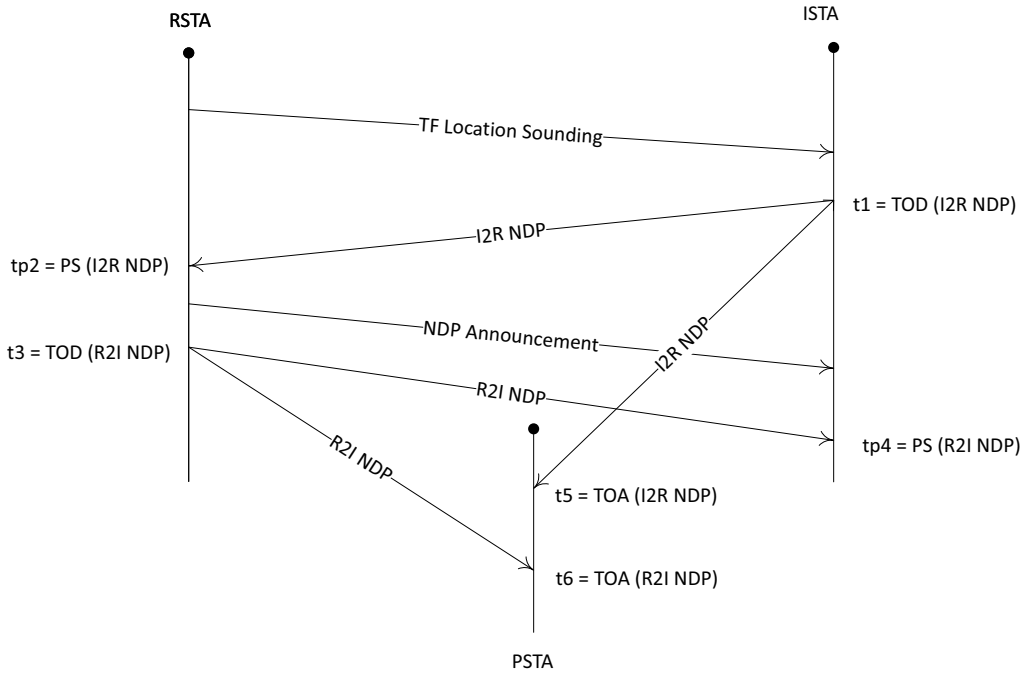

Figure 11-75—Example of passive TB ranging measurement exchanges with PSTOA measurements

The RSTA measures the PSTOA tp2 and the ISTA measures the PSTOA tp4, in addition to measuring their TODs t3 and t1. respectively. The ISTA also measures its CFO with respect to the RSTA. The ISTA reports its CFO and timestamps to the RSTA and the RSTA broadcasts these as well as its own timestamps to the PSTA.

The ISTA also measures and reports the TOA timestamps for the ranging NDPs it receives and the RSTA also measures and broadcasts the TOAs of the ranging NDPs it receives, as well as the ISTAs reported TOAs, though these timestamps are not used in the calculations described here.

The differential time of flight from the PSTA to the RSTA and the ISTA (DToF_PRI) is defined by Equation (11-13):

$$\text{DToF\_PRI} = \text{ToF\_PR} - \text{ToF\_PI} \tag{11-13}$$

where

ToF_PR	is the time of flight between the PSTA and the RSTA
ToF_PI	is the time of flight between the PSTA and the ISTA

The differential time of flight (DToF_PRI) can then be computed as per Equation (11-14):

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

$$DToF\_PRI = t6 - t5 - 0.5 \times t3' + 0.5 \times tp2' - 0.5 \times tp4' + 0.5 \times t1' \quad (11\text{-}14)$$

where

timestamp t1'	is the time at which the I2R NDP was transmitted from the ISTA.
timestamp tp4'	is the PSTOA measurement for the time at which the R2I NDP was received by the ISTA, converted from the ISTA's time basis to the PSTA's time basis.
timestamp tp2'	is the PSTOA measurement for the time at which the I2R NDP was received by the RSTA.
timestamp t3'	is the time at which the R2I NDP was transmitted from the RSTA, converted from the RSTA's time basis to the PSTA's time basis.

At the PSTA, the mechanism by which t1' and tp4' is derived from t1, tp4, the ISTA's reported CFO, and the PSTA's CFO measured with respect to the RSTA is implementation dependent.

At the PSTA, the mechanism by which t2' and tp3' is derived from t2, tp3, and the PSTA's CFO measured with respect to the RSTA is implementation dependent.

11.21.6.5 FTM parameter modification

During an FTM session, an ISTA may terminate the current session and request a new session with modified session parameters by transmitting an FTM Request frame with Trigger field set to 1.

This FTM Request shall include:

— A new FTM Parameters element if the corresponding FTM session is using an EDCA based measurement exchange; see 11.21.6.4.2 or,

— A Ranging Parameters element if the corresponding FTM session is of type non-TB ranging; see 11.21.6.4.4, or TB ranging; see 11.21.6.4.3.

NOTE—This allows up to one ranging session between a given ISTA and RSTA at any time.

The existing FTM session is terminated upon reception of such an FTM Request frame. This FTM Request frame is an initial FTM Request frame for the new FTM session, which follows the behavior described in 11.21.6.3.

11.21.6.5.1 Availability window parameter modification

In an FTM session based on TB ranging, the RSTA may modify the availability window parameters corresponding to the FTM session by transmitting an A-MPDU containing an FTM frame and an R2I LMR whenever the RSTA is permitted to transmit such an LMR to that ISTA. The FTM frame is of type Action No Ack and shall contain a Ranging Parameters field containing a TB-Specific subelement. The Availability Window field in the TB-Specific subelement indicates the parameters of the new availability window assigned to the corresponding FTM session. In the FTM frame the Follow Up Dialog Token field is set as 0. The existing ranging session continues based on current availability window parameters until the start of the new availability window signaled in the FTM frame.

11.21.6.6 FTM session termination

11.21.6.6.1 EDCA based ranging session termination

An FTM session terminates after the last burst instance, as indicated in the Number of Bursts Exponent, Burst Duration, FTMs Per Burst and Burst Period fields in the IFTM frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An FTM session may be terminated before then through one of the following:

- At any time during the FTM session when the RSTA is permitted to transmit an FTM frame (see 11.21.6.4), the RSTA sends an FTM frame with the Dialog Token field set to 0.
- At any time during the FTM session when the ISTA is permitted to transmit an FTM Request frame (see 11.21.6.4), the ISTA sends an FTM Request frame with the Trigger field set to 0. This frame shall not include the following:
  - A Measurement Request element
  - An FTM Parameters element
- At any time during the FTM session when the initiating STA is permitted to transmit an FTM Request frame (see 11.21.6.4), the ISTA terminates the current session and requests a new session with modified FTM parameters (see 11.21.6.5).
- After the number of burst instances indicated in the Number of Bursts Exponent field in the IFTM frame has been reached.

When the FTM session is a Secure FTM Session, the FTM frames transmitted shall be the Protected Fine Timing Action frames; see 9.6.34.

11.21.6.6.2 TB ranging and non-TB ranging session termination

A non-TB ranging FTM session may be terminated if an ISTA does not initiate a non-TB ranging measurement exchange (11.21.6.4.4) with an RSTA before the duration signaled in the Max Time Between Measurements field assigned to that ISTA by the RSTA has elapsed from either the end of the successful FTM session negotiation or the beginning of the last successful measurement exchange, whichever is later.

A TB ranging FTM session may be terminated if the ISTA fails to respond to a TF Ranging Poll frame and receive one TF Ranging Sounding frame or TF Ranging Secured Sounding frame containing its AID/RSID at least once within the Max Session Expiry interval. The Max Session Expiry interval starts from either the end of the successful FTM session negotiation or the beginning of the last successful TB ranging measurement exchange (11.21.6.4.3), whichever is later. The length of this interval is equal to the duration signaled in the Max Session Exp field, present in the TB Ranging Specific subelement in the Ranging Parameters field in the initial FTM frame.

A TB ranging or a non-TB ranging FTM session may be terminated through one of the following:

- At any time during the session when the RSTA is permitted to transmit an R2I LMR frame, the RSTA transmits an A-MPDU containing an LMR frame and an FTM frame with the Dialog Token field set to 0 and of type Action No ACK. In the FTM frame the Follow Up Dialog Token field is set as 0. The FTM frame shall not include any Ranging Parameters field.
- At any time during the session the ISTA sends an FTM Request frame with the Trigger field set to 0. This frame shall not include the following:
  - Ranging Parameters element.
  - Measurement Request element.
- At any time during the session the ISTA terminates the current session and requests a new session with modified ranging parameters; see 11.21.6.5.

When the ranging session is a Secure FTM Session, the corresponding FTM frames transmitted shall be Protected Fine Timing Action frames; see 9.6.34.

11.21.6.7 LCI and Location Civic retrieval using FTM procedure

Within the FTM procedure, a STA, to request the LCI of an RSTA that transmits an Extended Capabilities element with the Fine Time Measurement Responder field set to 1, shall include a Measurement Request element with Measurement Type field equal to LCI within the FTM Request frame.

Within the FTM procedure, a STA, to request the Location Civic of an RSTA that transmits an Extended Capabilities element with the FTM Responder field set to 1, shall include a Measurement Request element with Measurement Type field equal to Location Civic within the FTM Request frame.

A Measurement Request element with Measurement Type field equal to LCI shall not be included in an FTM Request frame unless the FTM Request frame also includes an FTM Parameters element or a Ranging Parameters element. A Measurement Request element with Measurement Type field equal to Location Civic shall not be included in an FTM Request frame unless the FTM Request frame also includes an FTM Parameters element or a Ranging Parameters element.

When an RSTA that has both dot11FineTimingMsmtRespActivated and dot11RMLCIConfigured equal to true receives a Measurement Request element with Measurement Type field equal to LCI within an IFTMR frame, the RSTA shall include a Measurement Report element with Measurement Type field equal to LCI in the IFTM frame. If the maximum horizontal or vertical location error of the RSTA relative to a reference STA is known and this relative error is smaller than the absolute error indicated in the LCI subelement, then the RSTA may include a Relative Location Error subfield in the Measurement Report field. The RSTA shall not include a Measurement Report element with Measurement Type field equal to LCI in the FTM frame in the current FTM session unless the RSTA's LCI has changed since the last time it was reported to the initiating STA.

When a responding STA that has at least one of dot11FineTimingMsmtRespActivated and dot11RMLCIConfigured equal to false receives a Measurement Request element with Measurement Type field equal to LCI within an FTMR frame, the responding STA shall include a Measurement Report element with the Incapable field set to 1 in the initial FTM frame.

When a responding STA that has both dot11FineTimingMsmtRespActivated and dot11RMCivicConfigured equal to true receives a Measurement Request element with Measurement Type field equal to Location Civic within an IFTMR frame, the responding STA shall include a Measurement Report element with Measurement Type field equal to Location Civic in the initial FTM frame. The responding STA shall not include a Measurement Report element with Measurement Type field equal to Location Civic in the FTM frame in the current FTM session unless the responding STA's civic location has changed since the last time it was reported to the initiating STA.

When a responding STA that has at least one of dot11FineTimingMsmtRespActivated and dot11RMCivicConfigured equal to false receives a Measurement Request element with Measurement Type equal to Location Civic within an FTMR frame, the responding STA shall include a Measurement Report element with the Incapable field set to 1 in the initial FTM frame.

Each Measurement Report element returned shall have the same Measurement Token value as in the Measurement Token field of the corresponding Measurement Request element. The FTM frame containing the Measurement Report element(s) should be returned without undue delay to the STA.

A STA that receives an LCI report that contains a Usage Rules/Policy subelement shall process the LCI information in compliance with the retransmission and retention permissions in the Usage Rules/Policy subelement.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.21.7 BSS transition management

11.21.7.1 BSS transition capability

The BSS transition capability enables improved throughput, effective data rate and/or QoS for the aggregate of STAs in a network by shifting (via transition) individual STA traffic loads to more appropriate points of association within the ESS. In addition, the BSS transition capability provides accounting session control information to a non-AP STA, which might be used to provide an alert to the non-AP STA's user that the STA's session is almost over and the STA will be disassociated from the ESS.

The BSS Transition Management Query, BSS Transition Management Request, BSS Transition Management Response frames provide a means and a protocol to exchange the information needed to enable an AP to inform associated STAs that the BSS will be terminated and to enable a network to manage BSS loads by influencing STA transition decisions. A STA may provide neighbor report information to its associated AP for BSSs that it considers to be transition targets. This information enables the AP to request that the STA transition to a BSS that the STA also prefers.

Implementation of BSS transition management is optional for a WNM STA that is not a non-AP HE STA. If dot11BSSTransitionActivated is true, dot11WirelessManagementImplemented shall be true. A STA with dot11BSSTransitionActivated equal to true shall support BSS transition management and shall set to 1 the BSS Transition field of the Extended Capabilities elements that it transmits. A non-AP HE STA shall have dot11BSSTransitionImplemented and dot11BSSTransitionActivated equal to true.

BSS transition management and network load balancing do not apply in an IBSS.

11.21.7.2 BSS transition management query

A non-AP STA supporting BSS transition management may request a BSS Transition Candidate list by sending a BSS Transition Management Query frame to its associated AP if the associated AP indicates that it supports the BSS Transition capability in the Extended Capabilities element. A non-AP STA should include the BSS Transition Candidate List Entries field in the BSS Transition Management Query frame to indicate the non-AP STA's transition preferences. If the non-AP STA transmits a BSS Transition Query frame only to provide transition preferences to the AP, then the BSS Transition Query Reason field of the BSS Transition Management Query frame shall be set to a value of 19, indicating "Preferred BSS Transition Candidate List Included."

The BSS Transition Candidate List Entries field of a BSS Transition Management Query frame contains zero or more Neighbor Report elements describing the non-AP STA's preferences for target BSS candidates. The Preference field value of a Neighbor Report element used in a BSS Transition Management Query frame shall be between 1 and 255. The value of 0 is reserved. The values between 1 and 255 provide the indication of order, with 255 indicating the most preferred BSS within the given candidate list, decreasing numbers representing decreasing preference relative only to entries with lower values of the Preference field, and equal numbers representing equal preference.

11.21.7.3 BSS transition management request

An AP that supports BSS transition management shall respond to a BSS Transition Management Query frame with a BSS Transition Management Request frame. The AP may send an unsolicited BSS Transition Management Request frame to a non-AP STA at any time if the non-AP STA indicates in the Extended Capabilities element that it supports BSS transition management; otherwise the AP shall not send an unsolicited BSS Transition Management Request frame to the STA. The AP may transmit a broadcast BSS Transition Management Request frame if at least one associated non-AP STA supports BSS transition management; otherwise the AP shall not transmit a broadcast BSS Transition Management Request frame. When the BSS Transition Management Request frame is transmitted as a broadcast frame, a receiving non-AP

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

STA shall not respond with a BSS Transition Management Response frame. A non-AP STA that supports BSS transition management shall respond to an individually addressed BSS Transition Management Request frame with a BSS Transition Management Response frame.

The AP shall include the BSS Transition Candidate List Entries field in the BSS Transition Management Request frame if the AP has information in response to the BSS Transition Management Query frame. The BSS Transition Candidate List Entries field contains zero or more Neighbor Report elements describing the preferences for target BSS candidates. A Preference field value of 0 indicates that the BSS listed is an excluded BSS. The STA should refrain from associating to an AP corresponding to an excluded BSS. The Preference field values are used to establish the relative order of entries within the given list at the given time, and for the given AP.

The values between 1 and 255 provide the indication of order, with 255 indicating the most preferred BSS within the given candidate list, decreasing numbers representing decreasing preference relative only to entries with lower values of the Preference field, and equal numbers representing equal preference. The Preference field value is valid only before the validity interval has expired. The AP may include zero or more subelements in the BSS Transition Candidate List Entries field.

Upon reception of a BSS Transition Management Query frame or BSS Transition Response frame from a non-AP STA that contains a nonempty BSS Transition Candidate List Entries field, the AP should include at least one BSS candidate from that list with a nonzero Preference field value in the BSS Transition Candidate List Entries field of any subsequent BSS Transition Management Request frame with the Preferred Candidate List Included field set to 1 transmitted to the non-AP STA. The AP shall evaluate the BSSs indicated in the BSS Transition Candidate List Entries field in the latest BSS Transition Management Query frame or BSS Transition Management Response frame received from the non-AP STA as BSS transition candidate(s) for the non-AP STA. The means by which the AP evaluates and determines BSS transition candidates is outside the scope of this standard.

A STA that receives a BSS Transition Management Request frame with the Preferred Candidate List Included subfield of the Request Mode field equal to 0 may ignore the BSS Transition Candidate List Entries field of the frame.

A non-AP STA that receives the Abridged bit with a value of 1 shall treat any BSSID in the ESS of which it is a member that does not appear in the BSS Transition Candidate List as if it were present in the BSS Transition Candidate List with a Preference value of 0.

The AP may include one BSS Termination Duration subelement for each BSS in the BSS Transition Candidate List Entry field, including the BSS Termination Duration value and a BSS Termination TSF value. The BSS Termination Duration value may be different for each BSS.

When the AP transmits a BSS Transition Management Request frame with the Disassociation Imminent field set to 1 to a non-AP STA, the Disassociation Timer field in the BSS Transition Management Request frame shall be set to 0 or set to the number of TBTTs that will occur prior to the AP disassociating the non-AP STA. The AP shall start a timer for the non-AP STA with the initial timer value set to the Disassociation Timer field value. The AP shall decrement the timer by one after transmitting each Beacon frame until the timer has value of 0. In subsequent BSS Transition Management Request frames that the AP transmits to the non-AP STA, the Disassociation Timer field shall be set to the value of the timer.

If the most recent BSS Transition Management Request frame that an AP has transmitted to a non-AP STA has the Disassociation Imminent field set to 1, then the AP shall not transmit a Disassociation frame to the non-AP STA unless the timer for the non-AP STA has value of 0.

An AP’s SME may have accounting session control information, such as a notice of session expiration. The means by which the AP’s SME obtains accounting session control information is out of scope of this standard.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Accounting session control information might include a duration after which the non-AP STA will be disassociated from the ESS and an optional session information URL at which information may be obtained to extend the accounting session. When an AP's SME has accounting session control information, it shall issue an MLME-BTM.request primitive to the AP's MLME and shall encode the time to session expiration in the Disassociation Timer parameter and shall encode the URL, if available, in the SessionInformationURL parameter. A non-AP STA's SME that receives an MLME-BTM.indication primitive shall forward the MLME-BTM.indication parameters to the appropriate entity within the device (e.g., web browser) to inform the end user; the means and protocol by which the SME accomplishes this is outside the scope of this standard.

A STA's SME receiving an MLME-BTM.indication primitive containing the BSS Transition Candidate List Entries field should use this list of candidates, with individual transition preference values, to make BSS transition decisions. Upon receiving an MLME-BTM.indication primitive, the STA's SME shall disregard any previous MLME-BTM.indication primitive received from the same AP. The STA shall not use the corresponding BSS Transition Candidate List Entries field information after the indicated validity interval. The STA may send a BSS Transition Management Query frame at any time to obtain an updated BSS Transition Candidate List Entries field or to indicate the STA's BSS transition candidates.

A STA's SME receiving an MLME-BTM.indication primitive containing a nonzero value of the Disassociation Timer field should attempt to find a suitable AP with which to reassociate before the indicated disassociation time.

11.21.7.4 BSS transition management response

When the STA's SME receives an MLME-BTM.indication primitive, it may issue an MLME-BTM.response primitive.

The STA's SME may include the result of its BSS transition decision in the Target BSSID field and BTM Status Code field in the MLME-BTM.response primitive. A BTM Status Code field set to a value of 0 (i.e., Accept) indicates the STA will transition from the current BSS. If a non-HE STA's SME receives an MLME-BTM.indication primitive indicating a BSS transition management request with which it is unable to comply, it may issue an MLME-BTM.response primitive with a status code indicating rejection.

When a non-AP STA's SME receives an MLME-BTM.indication primitive with the BSS Termination Included field in the Request Mode field equal to 1 it may issue an MLME-BTM.response primitive with the BTM Status Code field set to one of the following values:

— 0 – Accept. Accept the BSS Termination request.
— 4 – Reject, BSS Termination Undesired. Request for deferral of BSS Termination, interval not specified.
— 5 – Reject, BSS Termination Delay. Request for deferral of BSS Termination interval specified in the BSS Termination Delay field in the BSS Transition Management Response frame.

The AP's SME may abandon or delay its BSS termination decision based on policies that are out of the scope of this standard. The MLME-RESET.request primitive is invoked to terminate the BSS. The AP shall disassociate all STAs immediately prior to termination of the BSS.

When a non-AP STA's SME receives an MLME-BTM.indication primitive with both the Disassociation Imminent and Preferred Candidate List Included fields equal to 0, the non-AP STA's SME shall issue an MLME-BTM.response primitive with the BTM Status Code field set to one of the following values:

— 0 – Accept.
— 2 – Reject, Insufficient Beacon or Probe Response frames received from all candidates.
— 3 – Reject, Insufficient available capacity from all candidates.
— 6 – Reject, STA BSS Transition Candidate List provided.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— 7 – Reject, No suitable BSS transition candidates.
— 8 – Reject, Leaving ESS.

When an AP's SME receives an MLME-BTM.confirm primitive with the BTM Status Code field equal to a value of 2, indicating "Reject, Insufficient Beacon or Probe Response frames received from all candidates," the AP's SME should generate an MLME-BTM.request primitive with both the Disassociation Imminent and Preferred Candidate List Included fields set to 0 after providing sufficient time for the non-AP STA to perform its scanning procedures.

If the BTM Status Code field is a value of 6, indicating "Reject, STA BSS Transition Candidate List provided," the non-AP STA shall include a nonempty BSS Transition Candidate List Entries field in the BSS Transition Management Response frame to indicate the non-AP STA's transition preferences. The BTM Status Code field is a value of 8, indicating "Reject, Leaving ESS" if the non-AP STA intends to disassociate from the ESS.

The BSS Transition Candidate List Entries field of a BSS Transition Management Response frame contains zero or more Neighbor Report elements describing the non-AP STA's preferences for target BSS candidates. The Preference field value of a Neighbor Report element used in a BSS Transition Management Response frame shall be between 1 and 255. The value of 0 is reserved. The values between 1 and 255 provide the indication of order, with 255 indicating the most preferred BSS within the given candidate list, decreasing numbers representing decreasing preference relative only to entries with lower values of the Preference field, and equal numbers representing equal preference. The non-AP STA should not list any BSS that is not considered as a target BSS candidate.

When a non-AP STA receives a BSS Transition Management Request frame that has both the Disassociation Imminent and Preferred Candidate List Included fields equal to 1 and a nonempty BSS Transition Candidate List Entries field, if the non-AP STA transmits a BSS Transition Management Response frame to the AP with the BTM Status Code field set to 0 (Accept), then the non-AP STA shall either disassociate from the AP or attempt to (re)associate with an AP corresponding to one of the nonexcluded BSSs in the BSS Transition Candidate List Entries field of the received BSS Transition Management Request frame.

Prior to transitioning to an excluded BSS listed in the BSS Transition Candidate List Entries field of a received BSS Transition Management Request frame, the non-AP STA shall transmit a BSS Transition Management Response frame to the AP indicating the reject reason.

11.21.7.5 Planned ESS

The AP may transmit an ESS Report element (see 9.4.2.255) to indicate whether it is in a planned ESS, to assist associated STAs' BSS transition. If it indicates that it is in a planned ESS, it indicates whether it is at the physical edge of the ESS and can provide a recommendation on the RSSI level to consider for BSS transition.

If the AP transmits an ESS Report element, it shall set the Planned ESS subfield in the ESS Information field to 1 if it is part of an ESS that is planned with several BSSs in overlapping configuration, whereby an associated STA may adjust its BSS transition algorithms accordingly. Otherwise, it shall set the Planned ESS subfield to 0.

If the Planned ESS subfield is 1, then the AP shall set the Edge Of ESS subfield in the ESS Information field of the ESS Report element to 1 if the AP's BSS is at the edge of an ESS (e.g., exit of a building). Otherwise, it shall set the Edge Of ESS subfield to 0.

NOTE 1—A non-AP STA could then prepare for more aggressive BSS transition, or the device in which the non-AP STA is located could then prepare for switching to a different system. However, how the non-AP STA uses the edge of ESS information is implementation specific and beyond the scope of this standard.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the Planned ESS subfield is 1, then the AP shall set the Recommended BSS Transition RSSI Threshold Within ESS subfield in the ESS Information field of the ESS Report element to indicate the beacon RSSI below which an associated STA should initiate a BSS transition. Otherwise, it shall set the Recommended BSS Transition RSSI Threshold Within ESS subfield to 0.

NOTE 2—A non-AP STA could then use the Recommended BSS Transition RSSI Threshold Within ESS subfield to modify when it starts scanning for a new BSS. However, how the non-AP STA adjusts its BSS transition algorithms is implementation specific and beyond the scope of this standard.

The value of the Edge Of ESS subfield and the Recommended BSS Transition RSSI Threshold Within ESS subfield may be changed by the AP if conditions in the ESS change. An AP shall not change the value of the Planned ESS subfield over the lifetime of the BSS.

11.21.8 FMS multicast rate processing

An AP that supports FMS indicates its ability to deliver group addressed frames at alternate delivery intervals by its advertisement of the FMS capability. A STA that supports FMS includes the FMS Request element in FMS Request frames to indicate a request to use the FMS service, including use of a higher multicast rate. The AP selects the TXVECTOR parameters to use with the STA and indicates the rate that these parameters produce and the multicast address in the FMS Response element in the FMS Response frame.

The AP selects TXVECTOR parameters to be used for transmission to the currently associated STAs requesting FMS service from the AP for the same FMS stream identified by FMSID (the “existing STAs”), and to the requesting STA subject to the following constraints:

- The rate shall not be higher than the lowest rate value provided by the existing STAs and the requesting STA
- The selection of the following TXVECTOR parameters shall be compatible with capabilities declared by the existing STAs and the requesting STA:
  - FORMAT
  - NON_HT_MODULATION
  - PREAMBLE_TYPE
  - MCS
  - CH_BANDWIDTH
  - STBC
  - FEC_CODING
  - GI_TYPE

The STA’s SME may request membership in a multicast group or changes in multicast data rate by issuing an MLME-FMS.request primitive. Upon receipt of an FMS Request frame at the AP’s SME as indicated by reception of the MLME-FMS.indication primitive the AP’s SME shall issue an MLME-FMS.response primitive, indicating the FMS Request element, including the multicast address. The AP may send an FMS Response frame to the STA to change the STA’s multicast rate. When the AP sends an FMS Response frame to the STA with an Element Status field, indicating “Multicast rate changes not allowed,” the STA shall not send further FMS Request frames to request a change in the multicast rate while the STA is associated to the AP.

11.21.9 Colocated interference reporting

Colocated interference might cause degradation of IEEE 802.11 STA performance either periodically or continuously. Colocated interference reporting allows a requesting STA to receive information concerning the colocated interference being experienced by another STA that is operating on the same channel as the requesting STA. Such interference might be due to an interaction between radios where a reporting STA is

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

colocated with another radio device. Colocated interference information might be used by the requesting STA to manage communication to the reporting STA such that the effect of the interference might be limited.

Implementation of Colocated interference reporting is optional for a WNM STA. A STA that implements Colocated Interference reporting has dot11CoLocIntfReportingImplemented equal to true. When dot11CoLocIntfReportingImplemented is true, dot11WirelessManagementImplemented shall be true. A STA with dot11CoLocIntfReportingActivated equal to true shall support colocated interference reporting and shall set to 1 the Colocated Interference Reporting field of the Extended Capabilities elements that it transmits.

A requesting STA may request that colocated interference reporting is enabled at another STA that has indicated support for the interference reporting capability. To enable colocated interference reporting, the STA shall send a Colocated Interference Request frame with Automatic Response Enabled bit set to the value representing the requested reporting type; see 9.6.13.13. A STA accepting a request for colocated interference reporting shall send the first report when it has knowledge of colocated interference.

Subsequently, a STA accepting a request with the Automatic Response Enabled subfield equal to 1 shall send a colocated interference report when the temporal characteristics of the interference or the level of the interference caused by colocated interferer significantly change to provide updated information, subject to meeting the Report Timeout requirement. A STA accepting a request with the Automatic Response Enabled subfield equal to 2 or 3 shall send the colocated interference reports periodically using the period included in the Report Period field in the Colocated Interference Reporting element in the report frames. In addition to sending reports periodically, a STA accepting a request with the Automatic Response Enabled field equal to 3 shall send a colocated interference report when the temporal characteristics of the interference or the level of the interference caused by colocated interferer significantly change, subject to meeting the Report Timeout requirement.

The criteria a reporting STA uses for determining significant changes are internal to the reporting STA and outside the scope of this standard. When the reporting STA sends a colocated interference report, it shall restart the Report Period timer for periodic reporting. For either periodic reporting or reporting due to the changes in colocated interference, the reporting STA shall not generate colocated interference reports more frequently than indicated by the Report Timeout field in Interference Request field in the Colocated Interference Request frame.

The requesting STA may disable reporting by sending a Colocated Interference Request frame with the Automatic Response Enabled subfield set to 0. The colocated interference reporting shall be terminated on receipt of a Colocated Interference Request frame with the Automatic Response Enabled subfield equal to 0. All outstanding colocated interference requests are canceled upon a BSS transition and/or channel switch. A new colocated interference request included in the new colocated Interference Request frame supersedes any previously received requests sent by the same STA.

A STA that supports colocated interference reporting may send a Colocated Interference Request frame to another STA that supports colocated interference reporting immediately after they are associated, so that the reporting STA can send a colocated interference report as soon as it has knowledge of colocated interference. The Dialog Token field is the nonzero value received in the corresponding Colocated Interference Request frame which was used to enable reporting.

The reporting STA shall use the Interference Index field in the Colocated Interference Report frame to indicate different types of interference. The reporting STA shall select a unique interference index value for each colocated interference source. For example if the reporting STA has knowledge of colocated interference originating from two interference sources the reporting STA shall report both type of interference using separate Colocated Interference Report elements having separate Interference Index field. Both Colocated Interference Report elements can be sent in the same Colocated Interference Report frame and both can have the same report period. A report with the Interference Index field in the Colocated Interference Report element equal to 0 indicates that no colocated interference is present.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The characteristics of the interference are known a priori without requiring interference detection, measurement, and characterization by the IEEE 802.11 STA. The methods used by a reporting STA to know the periodicity, level of interference, accuracy of the reported interference level, interference center frequency and interference bandwidth are outside the scope of this standard.

11.21.10 QoS Traffic capability procedure

Implementation of the QoS Traffic capability is optional for a WNM STA. A STA that implements QoS Traffic capability has dot11QoSTrafficCapabilityImplemented equal to true. When dot11QoSTrafficCapabilityImplemented is true, dot11WirelessManagementImplemented shall be true. A STA with dot11QoSTrafficCapabilityActivated equal to true shall support QoS traffic capability and shall set to 1 the QoS Traffic Capability field of the Extended Capabilities elements that it transmits.

If dot11QoSTrafficCapabilityActivated is true, a QoS AP may use the QoS Traffic Capability field values received from a non-AP QoS STA as one of the factors when determining association, reassociation, and the BSS transition of the STA. A non-AP STA in which dot11QoSTrafficCapabilityActivated is true may send an Association Request, a Reassociation Request or QoS Traffic Capability Update frame to an AP whose last received Extended Capabilities element contained a value of 1 for the QoS Traffic Capability subfield in the Extended Capabilities field.

If dot11QoSTrafficCapabilityActivated is true, a non-AP QoS shall construct the QoS traffic capability flags as specified in 9.4.2.76 and 9.6.13.23. QoS traffic capability flags are constructed at the SME of the non-AP QoS STA, from application requirements supplied to the SME. The QoS traffic capability flags are constructed from two application requirements: whether generation of traffic is required for applications and whether a specific UP is required for the generated traffic. If such requirements are supplied to the SME, the SME shall set the flag corresponding to the specific UP to 1.

NOTE—The requirements might be known before the traffic is actually generated. For example, a phone application might configured to generate UP 6 traffic upon the initiation of a voice session.

Unless application requirements for a specific UP are supplied to the SME, the SME shall set the flag corresponding to the UP to 0.

If dot11QoSTrafficCapabilityActivated is true, a non-AP QoS STA shall include the QoS Traffic Capability element in an Association Request frame or in a Reassociation Request frame when it is sending such a frame to associate or reassociate with an AP. If there is any change in QoS traffic capability flags while associated with an AP, the non-AP STA shall send a QoS Traffic Capability Update frame (see 9.6.13.23) including the updated QoS traffic capability flags to the AP.

11.21.11 AC Station Count

Implementation of AC Station Count is optional for a WNM STA. A STA that implements AC station count has dot11ACStationCountImplemented equal to true. When dot11ACStationCountImplemented is true, dot11WirelessManagementImplemented and dot11QoSTrafficCapabilityImplemented shall be true. When dot11ACStationCountActivated is true, the STA shall set the AC Station Count field to 1 in the Extended Capabilities element to indicate that the STA supports the AC station count capability. When dot11ACStationCountActivated is false, the STA shall set the AC Station Count field in the Extended Capabilities element to 0 to indicate that the STA does not support this capability.

If dot11ACStationCountActivated is true, a QoS AP shall construct the QoS traffic capability bitmask and AC STA count list as specified in 9.4.2.76. The AP shall construct the STA Count List value based on the UP-to-AC mappings as defined in Table 10-1, the QoS traffic capability bitmask/flags of the non-AP STAs that are currently associated with it, and additional information. If dot11ACStationCountActivated is true, a QoS AP shall include the QoS Traffic Capability element in a Probe Response frame and in a Beacon frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If dot11ACStationCountActivated is true, a non-AP QoS STA may use the STA Count field values as one of the factors when determining association, reassociation, and the BSS transition. If dot11ACStationCountActivated is false, a non-AP QoS STA shall not use the STA Count field values as one of the factors when determining association, reassociation, and the BSS transition.

11.21.12 TFS procedures

11.21.12.1 TFS capability

Implementation of the TFS capability is optional for a WNM STA. A STA that implements TFS shall set dot11TFSImplemented to true. If dot11TFSImplemented value is true, then dot11WirelessManagementImplemented shall be true. A STA with dot11TFSActivated equal to true shall support TFS and shall set to 1 the TFS field in the Extended Capabilities elements that it transmits.

A STA in which dot11TFSActivated is true may send a TFS Request, TFS Response, TFS Notify frame, or TFS Notify Response frame to a STA within the same infrastructure BSS whose last received Extended Capabilities element contained a value of 1 for the TFS bit in the Extended Capabilities field. The traffic filtering service is not supported in an IBSS.

A traffic filtering agreement is established using a TFS Request frame transmitted from a non-AP STA to an AP and a TFS Response frame transmitted from the AP to the non-AP STA. At most one traffic filtering agreement can exist at any one time between a STA and its associated AP.

A traffic filtering agreement comprises one or more traffic filter sets, with a logical OR operation on the match conditions of each traffic filter set.

A traffic filter set contains one or more traffic filters, with a logical AND operation on the match conditions of each traffic filter, and also includes a traffic filter set action. The traffic filter set action defines the actions taken at the AP when a frame match occurs. A frame match occurs when a frame matches to the filtering parameters for a TFS traffic filter set.

NOTE—The frame match can occur when the matched frames are either individually addressed or group addressed.

A TFS Request frame contains one or more TFS Request elements. Each traffic filter set is conveyed by one TFS Request element, within a TFS Request frame.

One TFS Request element contains one or more TFS Request subelements. A TFS Request subelement might be a TFS subelement, in which case it contains the filtering parameters for one traffic filter.

A TFS subelement contains one or more TCLAS elements and an optional TCLAS Processing element that defines the relationship among multiple TCLAS elements within the TFS subelement. The TCLAS Processing element shall be present if more than one TCLAS element is included in the TFS subelement.

A TFS Response frame contains the status of the traffic filters requested in the corresponding TFS Request frame.

An AP may propose alternative filtering parameters by returning a TFS subelement in the corresponding TFS Response subelement. (See 11.21.12.2 and 11.21.12.3). When an AP proposes alternative filtering parameters it shall ensure that the TFS subelements related to the traffic filter set specified by a single TFS Request element all fit within a single TFS Response element.

When an AP transmits a TFS Response frame to a STA in which the Status for all traffic filter requests is “Accept”, it shall enable TFS for the STA. The previously established filter parameters, if any, remain in effect when the AP transmits a TFS Response frame with any other Status.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When a traffic filter for group addressed frames is enabled at the AP, the group addressed frames are still delivered, without regard to the frames matching the traffic filter, since other associated STAs may also receive these frames. Because a STA using TFS can be in power save mode for an extended period of time, group addressed frames that match the traffic filter might be delivered before the STA is aware that the traffic filter has been matched. It is likely (but not guaranteed) that the STA does not receive those group addressed frames matching the traffic filter at the scheduled group addressed delivery time. To detect when this might have happened, the STA can request a notification frame be sent when requesting the establishment of the traffic filter. If negotiated with the AP, a frame match is indicated to the non-AP STA via a notification frame.

11.21.12.2 TFS non-AP STA operation

To use the TFS, the non-AP STA's SME that supports TFS shall issue an MLME-TFS.request primitive to send a TFS Request frame. The MLME-TFS.request primitive shall include a valid TFSRequest parameter as defined in the TFS Request elements.

The receipt of an MLME-TSF.confirm primitive with a valid TFSResponse parameter indicates to the STA's SME that the AP has processed the corresponding TFS request. The content of the TFSResponse parameter provides the status of each of the TFS Request elements processed by the AP. A TFSResponse parameter optionally contains modified filtering parameters for the corresponding TFS request.

A TFS Response frame in which the Status for all traffic filter requests is "Accept" indicates to the non-AP STA that the filtering operation at the AP has started. Otherwise, the STA might use the information in the TFS Response frame to form a new TFS request.

In order to request the AP to delete a traffic filter set (identified by a unique TFS ID) when a frame matches to the traffic filter set, a non-AP STA shall set the Delete After Match subfield of the TFS Action Code field of the TFS Request element in the TFS Request frame to 1.

In order to request a TFS Notify frame to be sent by the AP upon a frame match, a non-AP STA shall set the Notify subfield of the TFS Action Code field of the TFS Request element in the TFS Request frame to 1.

After receiving a TFS Notify frame, in order to request the AP to resume generation of the TFS Notify frame upon a future frame match, a non-AP STA shall transmit to the AP a TFS Notify Response frame containing one or more TFS IDs.

The non-AP STA may indicate that it is no longer using a particular TFS Request element by transmitting a TFS Request frame without that TFS Request element. The AP shall send a TFS Response frame with the corresponding Status field value set to Accept, upon receipt of the TFS Request frame.

The non-AP STA may choose to terminate use of the TFS service by sending a TFS Request frame with no TFS Request elements in the request thereby canceling all traffic filters at the AP.

11.21.12.3 TFS AP operation

When an AP's SME receives an MLME-TFS.indication primitive with a valid TFSRequest parameter, it shall issue an MLME-TFS.response primitive with a TFSResponse parameter indicating the status of the associated request.

An AP establishes a traffic filtering agreement and starts the filtering operation defined by that traffic filtering agreement when it receives an MLME-TFS.response primitive in which the Status for all traffic filter requests is "Accept".

When the AP establishes a traffic filtering agreement for a requesting STA, the AP shall add to the traffic filtering agreement a traffic filter set that matches individually addressed EAPOL-Key frames addressed to the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

requesting STA, with bits 0 and 1 of the TFS Action Code field set to 0, without any status indication for this traffic filter set in the TFS Response frame.

When an AP's SME receives an MLME-TFS.indication primitive with a valid TFSRequest parameter having a requested TCLAS-based classifier which it is unable to provide, the SME shall issue an MLME-TFS.response primitive indicating the status of the corresponding request and may include a TFSResponse parameter having a suggested alternative TCLAS-based classifier.

When a traffic filtering agreement is established for a STA, the AP shall discard all individually addressed frames destined for the STA until a frame is found that matches one or more traffic filter sets within the traffic filtering agreement. When a frame is found that matches one or more of the traffic filter sets within the traffic filtering agreement (a matching frame), the AP shall perform the following actions:

— If the traffic filter set action specifies both Delete After Match and Notify, then the AP shall generate a single individually addressed TFS Notify frame for the frames matching to the traffic filter set identified by the corresponding TFS ID. Subsequently, the AP shall delete the traffic filtering agreement.

— If the traffic filter set action specifies Notify but not Delete After Match, then the AP shall generate a single individually address TFS Notify frame for all frames matching to the traffic filter set identified by the corresponding TFS ID. All traffic filter sets established at the AP for the non-AP STA remain to be effective upon a match. If the AP receives a TFS Notify Response frame from the corresponding non-AP STA, the AP resumes generation of a single individually addressed TFS Notify frame for the next frame matching to the traffic filter sets identified by the TFS IDs included in the TFS Notify Response frame. Otherwise, the AP shall not send additional TFS Notify frames upon frame matches.

NOTE—Due to the operation of group addressed frame delivery, a group addressed frame that matches a traffic filter might result in the STA receiving indication of the group addressed frame either before or after the group addressed frame is transmitted by the AP, if the TFS Notify frame is queued in the STA's power save queue. This might result in the STA receiving the group addressed frame in some cases and not receiving it in other cases.

Upon receiving an MLME-TFS.indication primitive, the AP's SME shall disregard any previous MLME-TFS.indication primitive received from the same STA.

The AP shall terminate any TFS operation for a STA when no traffic filters remain for a STA or if the AP's SME receives an MLME-TFS.indication primitive with a null TFSRequest.

11.21.13 BSS max idle period management

If dot11BssMaxIdlePeriod is nonzero, an AP shall include the BSS Max Idle Period element in the (Re)Association Response frame. Otherwise, an AP shall not include the BSS Max Idle Period element in the (Re)Association Response frame. A non-S1G STA may send protected or unprotected keepalive frames, as indicated in the Idle Options field.

Extended BSS max idle period values are those that had a nonzero unified scaling factor (Table 9-78) value signaled by an S1G STA. A non-AP S1G STA may include the BSS Max Idle Period element in transmitted (Re)Association Request frames to indicate a preferred BSS max idle period value. The S1G AP chooses a value for BSS max idle period based on the S1G STA's preferred BSS max idle period (if any) and the type of the S1G STA. The S1G AP indicates its chosen value to the S1G STA in the (Re)Association Response frame.

If dot11WirelessManagementImplemented is true, dot11BSSMaxIdlePeriod is nonzero and dot11BSSMaxIdlePeriodIndicationByNonAPSTA is true, then a non-AP non-S1G STA shall include a BSS Max Idle Period element in the (Re)Association Request frame. If the BSS Max Idle Period element is present in the (Re)Association Request frame received by a non-S1G AP that has dot11BSSMaxIdlePeriodIndicationByNonAPSTA equal to true, then the non-S1G AP may choose the non-

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

AP STA's preferred maximum idle period. The non-S1G AP indicates its chosen value to the non-S1G STA in the (Re)Association Response frame.

The value chosen by the AP is the value that the AP will use in making disassociate decisions based on the timeout value equal to BSS max idle period for the non-AP STA that is the recipient of the (Re)Association Response frame. An AP may provide different values for BSS max idle period to different STAs.

A STA may send at least one protected or unprotected keepalive frame per BSS max idle period, as indicated in the Idle Options field. When a STA transmits an unprotected keepalive frame, it shall use a frame that has 48-bit TA and RA fields.

The Max Idle Period field of the BSS Max Idle Period element indicates the time period during which a STA can refrain from transmitting frames to its associated AP without being disassociated due to inactivity. A non-AP STA is considered inactive if the AP has not received a Data frame, PS-Poll frame, or Management frame (protected or unprotected as specified in this paragraph) of a frame exchange sequence initiated by the STA for a time period greater than or equal to the time specified by the Max Idle Period field. If the Idle Options field requires protected keepalive frames, then the AP may disassociate the STA if no protected frames are received from the STA for a duration of BSS max idle period. If the Idle Options field allows unprotected or protected keepalive frames, then the AP may disassociate the STA if no protected or unprotected frames with 48-bit TA and RA fields are received from the STA for a duration of BSS max idle period.

NOTE 1—The AP can disassociate or deauthenticate the STA at any time for other reasons even if the STA satisfies the keep-alive frame transmission requirements. An example of such other reason is group key rekeying. WNM sleep mode (see 11.2.3.15) might be used to avoid disconnection due to not replying to group key handshake message 1.

NOTE 2—A non-AP STA might be in doze state during a group key handshake when the AP advertises a BSS max idld period. The Authenticator might allow such a STA to remain associated even if it missed a new group key. If beacon protection is enabled, such a STA might not have the current BIGTK available when waking up from doze state. This might result in discarding Beacon frames due to MME validation errors. A STA might wait for a new BIGTK to be received through a subsequent group key handshake before disconnecting from the BSS due to beacon loss in cases where it did not wake up to receive buffered frames during a long doze state.

11.21.14 Proxy ARP service

Implementation of the proxy ARP service is optional for a WNM STA. A STA that implements the proxy ARP service has dot11ProxyARPImplemented equal to true. When dot11ProxyARPImplemented is true, dot11WirelessManagementImplemented shall be true. When dot11ProxyARPActivated is true, the Proxy ARP Service bit in the Extended Capabilities field shall be set to 1 to indicate that the AP supports the proxy ARP service. When dot11ProxyARPActivated is false, the Proxy ARP Service bit shall be set to 0 to indicate that the AP does not support the proxy ARP service.

When the AP sets the Proxy ARP field to 1 in the Extended Capabilities element, the AP shall maintain a Hardware Address to Internet Address mapping for each associated STA and for each IPv4 and IPv6 address of the STA, and shall update the mapping when one of the addresses of the associated STA changes. A Proxy ARP service receives and processes three types of messages: IPv4 ARP requests, IPv6 ND address lookups, and IPv6 ND duplicate address detection (DAD) messages. These messages are all received as group addressed. If the target address is not known, the Proxy ARP service does not forward the request to the BSS. If the target address is known, the Proxy ARP service can either respond directly on behalf of a STA or forward the request as an individually addressed frame to the intended STA. For fixed devices in doze state, a direct response is preferable. Otherwise, forwarding as an individually addressed frame is recommended, to avoid responding with misleading information.

For IPv4, when the address being resolved in the ARP request (IETF RFC 826) is used by a non-AP STA currently associated to the BSS, the proxy ARP service shall either respond on behalf of the STA to an ARP

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

request or an ARP probe (IETF RFC 5227) or preferably turn the ARP request into an individually addressed frame sent to that STA.

When an AP receives an IPv4 ARP request from one associated STA or from the DS with a target IPv4 address that corresponds to a second associated STA, the AP that decides to form a proxy ARP response frame shall insert the second STA MAC address as the sender's MAC address in the ARP response.

In contrast to IPv4, Stateless Address Autoconfiguration (SLAAC), which is part of IPv6 Neighbor Discovery (ND), enables a node to form multiple addresses, some of them temporary and with a particular attention paid to privacy. SLAAC addresses may be formed and deprecated asynchronously to the association. Even if the knowledge of IPv6 addresses used by a STA can be obtained by snooping protocols such as IPv6 ND and DHCPv6, or by observing data traffic sourced at the STA, such methods provide only an imperfect knowledge of the state of the STA at the AP, in particular when SLAAC is enabled. Running a Proxy ARP service on an incomplete set of addresses may result in a loss of connectivity, in particular for addresses rarely used and in situations of mobility.

This nondeterministic representation of IPv6 address location and binding may also result in undesirable state persistence in the AP when a STA ceases to use an IPv6 address. It follows that protocol snooping is not a recommended technique and that snooping should only be used as last resort. IETF RFC 8505 defines an address registration mechanism that enables the AP to maintain a deterministic knowledge of all the IPv6 addresses of all the associated STAs. IETF RFC 8929 defines a proxy ND service that leverages the address registration to maintain an accurate proxy state that follows the movements of the STAs, while IETF RFC 8928 protects the address ownership against impersonation attacks and address spoofing.

The proxy ARP function for IPv4 and IPv6 shall support snooping of DHCPv4, DHCPv6, and IPv6 ND to discover the IPv4 and IPv6 addresses owned by the STA.

For IPv6, since the state obtained by snooping SLAAC is unreliable, the proxy ARP function shall support the backbone router function defined in IETF RFC 8929, which creates a binding state based on an IETF RFC 8505 registration by the STA. The proxy ARP function should support IETF RFC 8928 to protect the ownership of the addresses. The non-AP STA shall support the address registration mechanism defined in IETF RFC 8505 and should support the address protection mechanism defined in IETF RFC 8928.

IPv6 ND uses IP layer multicast Internet Control Message Protocol version 6 (ICMPv6) Neighbor Solicitation (NS) messages (section 4.3 of IETF RFC 4861) for address resolution (section 7.2 of IETF RFC 4861), which is the equivalent of ARP request, and for duplicate address detection (DAD). The proxy ARP function shall discard those messages if the target IP address does not correspond to an associated STA. NS messages are sent as IP layer unicast for neighbor unreachability detection (NUD) (section 7 of IETF RFC 4861). The proxy ARP function shall not operate on IP layer unicast NS messages.

With the IPv6 ND proxy operation defined in IETF RFC 8929, the backbone router function at the AP typically operates as a bridging proxy though operation as a routing proxy is also possible. As a bridging proxy, the NS lookups are replied with the MAC address of the STA, and the packets to the STA are bridged normally; as a routing proxy, the backbone router function replies to lookups from the wired backbone with its own MAC address and then routes to the STA at the IP layer. The routing proxy isolates the layer-2 domains and hides the MAC address of the STA in the wired backbone, for a better stability and scalability of the bridged domain. The Proxy ARP function shall support the bridging proxy and may support the routing proxy operation.

When the target IPv6 address of a IP layer multicast NS message corresponds to an associated STA, the Proxy ARP service may respond on behalf of an associated low-power STA with a neighbor advertisement (NA) message (section 4.4 of IETF RFC 4861) with the override flag set to zero, to conserve energy. Preferably, though, the Proxy ARP service should transmit the IP layer multicast NS message as an individually addressed frame to the STA and let the STA respond, as recommended in IETF RFC 8929. When MAC address

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

mappings change, the AP may send unsolicited Neighbor Advertisement messages on behalf of a STA if the IPv6 Neighbor Discovery function at the STA failed to do so.

The IPv6 ND function at the STA shall register all of the IPv6 addresses on the interface (see section 10 of IETF RFC 8929) to the proxy ARP service at the AP to ensure that the proxy ARP service is aware of all those addresses and will proxy for them. The proxy ND operation may support address mobility (section 6 of IETF RFC 8929) to transfer a role of ND proxy for this STA to the AP with which the STA is associated following a mobility event.

11.21.15 Channel usage procedures

The channel usage procedures may be used to

— assist the STA that operates a channel-usage-aidable BSS or an off-channel TDLS direct link to better coexist with a set of channel-usage-aiding BSSs by exchanging Channel Usage Request and Response frames with an AP of the channel-usage-aiding BSS set, or

— for a STA to request a channel switch by sending a Channel Usage Request frame to the AP of a channel-usage-aidable BSS, or

— for a STA to notify its associated AP of its capability by exchanging Channel Usage Request and Response frames with its associated AP.

Implementation of channel usage is optional for a WNM STA. A STA that implements channel usage has dot11ChannelUsageImplemented equal to true. When dot11ChannelUsageImplemented is true, dot11WirelessManagementImplemented shall be true, or the STA shall support acting as an S-AP within a CCSS. A STA with dot11ChannelUsageActivated equal to true shall support channel usage and shall set to 1 the Channel Usage field of the Extended Capabilities elements that it transmits.

A Channel Entry field, in a Channel Usage element with Usage Mode field equal to 0 or 2 shall be interpreted as a recommendation for the indicated channel, and also for all narrower channels fully encompassed by the bandwidth of the indicated channel.

NOTE 1—For example, if such a Channel Usage element indicates global operating class 128 and channel 42 (80 MHz at 5 GHz) is a recommendation for that 80 MHz channel, and also for the two 40 MHz channels (36+40, 44+48) and the four 20 MHz channels (36, 40, 44, 48) within that 80 MHz channel.

The operating class(es) included in a Channel Usage element should be selected such that they are expected to be understood by the intended recipient(s) of the element. Operating Class And Channel fields in the Channel Entry field in a Channel Usage element that indicate channels that span a single contiguous bandwidth where the Channel Usage element is sent in a group addressed frame shall be interpreted as a recommendation for each of the identified channels and also for any channel that fully encompasses one or more of the identified channels and is within the contiguous bandwidth.

A TWT agreement that is established between a STA and its associated AP, by exchanging Channel Usage Request and Response frames, is referred to as a peer-to-peer TWT agreement and the corresponding TWT schedules are referred to as peer-to-peer TWT schedules. In this case, the Channel Usage element carried in the Channel Usage Request and Response frames may:

— include a single Channel Entry field with Operating Class And Channel field(s) that are different from the associated AP's BSS channel, or

— include a single Channel Entry field with Operating Class And Channel field(s) that are the same as the associated AP's BSS channel, or

— include no Channel Entry field.

Unless explicitly indicated in this subclause, the rules defined in 10.46 and in 26.8 shall be ignored when establishing and operating with a peer-to-peer TWT agreement.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 2—The TWT element is used for a peer-to-peer TWT agreement only to determine the timing parameters of the peer-to-peer TWT schedule.

An HE AP that has dot11ChannelUsageActivated equal to true and supports negotiating a peer-to-peer TWT schedule that is requested by a non-AP STA to establish a channel-usage-aidable BSS or an off-channel TDLS direct link shall set to 1 the Peer-to-peer TWT Support field of the Extended Capabilities elements that it transmits.

NOTE 3—An HE AP has dot11TWTOptionImplemented equal to true and has the TWT Responder Support subfield set to 1 in the Extended Capabilities element and the HE Capabilities element.

A non-AP STA that supports channel usage and is not associated to an AP prior to using a channel-usage-aidable BSS or an off channel TDLS direct link may transmit a Probe Request frame including both Supported Operating Classes and Channel Usage elements. A non-AP STA supporting channel usage may send a Channel Usage Request frame at any time after association to the AP that supports the use of channel usage to request the channel usage information for supported operating classes. A non-AP STA that transmits a Channel Usage Request frame shall set the Usage Mode field of the Channel Usage element to 2 if it requests assistance to setup a channel-usage-aidable BSS on an off-channel that does not have any infrastructure BSSs operated by any AP that belongs to the ESS of its associated AP. Otherwise, the non-AP STA shall set the Usage Mode field of the Channel Usage element to 0, 1 or 3.

A non-AP STA that supports channel usage and has the TWT Requester Support subfield set to 1 in the HE Capabilities element that it transmits, may negotiate a peer-to-peer TWT schedule with its associated AP, to indicate the service period, and optionally the channel operation, of a channel-usage-aidable BSS or an off-channel TDLS direct link, by transmitting a Channel Usage Request frame that includes TWT Elements and Timeout Interval Element fields, if the AP has the Peer-to-peer TWT Support field set to 1 in the Extended Capabilities element. Each TWT element carried in the TWT Elements field includes a single Individual TWT Parameter Set field whose subfields shall be set as described in 26.8.2 and 9.4.2.198 except that the TWT Group Assignment subfield shall be set to zero and the Responder PM Mode subfield, the Trigger subfield, the Flow Type subfield, and the TWT Channel subfield shall be reserved. Each TWT element in the TWT Elements field applies to all the Channel Entry subfields of the Channel Usage Elements field. The non-AP STA may indicate the lifetime of the requested peer-to-peer TWT agreement in the Timeout Interval Value field of the TIE that it includes in the Channel Usage Request frame and shall set the Timeout Interval Type field to 5.

A non-AP STA may send a Channel Usage Request frame to its associated AP with a TWT element configured as a TWT request. In this case, if the non-AP STA receives a Channel Usage Response frame from the AP that includes a TWT element configured as a TWT response with the TWT Setup Command field indicating Accept TWT, then the non-AP STA has successfully completed the peer-to-peer TWT agreement with the AP for the TWT flow identifier indicated in the TWT element that is carried in the Channel Usage Response frame. Otherwise, that peer-to-peer TWT agreement has not been established. The TWT flow identifier, together with the MAC addresses of the requesting STA and the responding AP, identifies the peer-to-peer TWT agreement.

NOTE 4—The AP might choose a value for the TWT Flow Identifier field in a TWT element carried in the Channel Usage Response frame that is different from the value of the TWT Flow Identifier field in the received Channel Usage Request frame.

To indicate its unavailability, a non-AP STA may transmit a Channel Usage Request frame with the Usage Mode field of the Channel Usage element set to 3 and without a Channel Entry field to inform the AP about its unavailability during the peer-to-peer TWT agreement, also referred to as unavailability notification. Otherwise, the non-AP STA shall set the Usage Mode field to 0, 1 or 2.

A non-AP STA that has successfully set up a peer-to-peer TWT schedule with its associated AP should use the negotiated peer-to-peer TWT SPs for communication not via the AP.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A non-AP STA may teardown a peer-to-peer TWT agreement by sending a TWT Teardown frame with the Negotiation Type subfield set to 0 and the TWT Flow Identifier field set to the value of the corresponding TWT flow identifier.

An AP shall not send a TWT Teardown frame to a non-AP STA to teardown any peer-to-peer TWT schedule between them.

An AP shall not send a TWT Information frame to a non-AP STA to suspend or resume any peer-to-peer TWT schedule between them.

NOTE 5—A peer-to-peer TWT agreement is a form of individual TWT agreement, and therefore, the total number of individual TWT agreements including peer-to-peer TWT agreements established between a non-AP STA and its associated AP cannot exceed 8, since the TWT Flow Identifier field of the TWT element comprises 3 bits.

A non-AP STA may suspend a peer-to-peer TWT agreement by sending a TWT Information frame with the TWT Flow Identifier field set to the value of the TWT Flow Identifier field of the TWT element in the Channel Usage Response frame that concluded the setup of the corresponding peer-to-peer TWT agreement if the AP has set the TWT Information Frame Disabled field to 0 in the TWT element sent during the TWT setup; otherwise, the non-AP STA shall not transmit a TWT Information frame to the AP. If the Next TWT subfield is present in the TWT Information frame, the value of the Next TWT subfield shall be selected from the future target wake times of the corresponding peer-to-peer TWT agreement.

NOTE 6—If the Next TWT subfield is present in the TWT Information frame, the peer-to-peer TWT agreement will resume at the time indicated in the Next TWT subfield.

Upon receipt of a Channel Usage element in the Probe Request frame, the AP supporting channel usage shall send a Probe Response frame including one or more Channel Usage elements. Upon receiving a Channel Usage Request frame with the Usage Mode field in a Channel Usage element set to 0 or 1, the AP supporting channel usage shall send a Channel Usage Response frame including one or more Channel Usage elements. Channel Usage elements shall include channels that are valid for the regulatory domain in which the AP transmitting the element is operating and consistent with the Country element in the Beacon or Probe Response frame; the Channel Usage elements shall not include any other channels. Upon receiving a Channel Usage Request frame with the Usage Mode field set to 2 in a Channel Usage element, an AP that supports channel usage shall send a Channel Usage Response frame with the Usage Mode field in the Channel Usage element set to 2 if the AP can determine that none of the APs belonging to the same ESS operate BSSs on the channels indicated by the Channel Entry field in the Channel Usage element of the response. Otherwise, the AP shall set the Usage Mode field of the Channel Usage element to 0, 1 or 3.

NOTE 7—The determination of which APs belonging to the same ESS operate BSSs on a particular channel is implementation dependent and beyond the scope of this standard.

Upon receiving a Channel Usage Request frame with a TWT element, an AP that supports peer-to-peer TWT scheduling shall send a Channel Usage Response frame including zero or one Channel Usage element that includes a Channel Entry field with only one Operating Class And Channel field, a TWT Elements field and may include a Timeout Interval Element field. Each TWT element carried in the TWT Elements field includes a single Individual TWT Parameter Set field whose subfields shall be set as described in 26.8.2 except that the TWT Group Assignment subfield shall be set to zero and the Responder PM Mode subfield, the Trigger subfield, the Flow Type subfield, and the TWT Channel subfield shall be reserved. The TWT element(s) in the TWT Elements field apply to the Channel Entry subfield of the Channel Usage Elements field, if present. When the lifetime of the peer-to-peer TWT agreement expires, the AP shall send a TWT Teardown frame to terminate that peer-to-peer TWT agreement.

NOTE 8—If the Usage Mode field set to 3, it is possible that the Channel Usage Request frame does not include a Channel Entry field. In such case, the TWT element indicates the unavailability of the requesting non-AP STA for communication with the AP during the peer-to-peer TWT schedule.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The outcome of the TWT setup when negotiating a peer-to-peer TWT agreement initiated by the exchange of Channel Usage Request and Channel Usage Response frames that carry a TWT element as described in this clause is the same as that defined in Table 10-40.

The AP shall not send an unsolicited Channel Usage Response frame with a TWT element to a non-AP STA.

An AP that successfully sets up a peer-to-peer TWT agreement after receiving a Channel Usage Request frame with a TWT Elements field from a non-AP STA may indicate the lifetime of the peer-to-peer TWT agreement for the corresponding TWT element(s) in the Timeout Interval Value field of the TIE that it includes in the Channel Usage Response frame and shall set the corresponding Timeout Interval Type field to 5. An AP that successfully sets up a peer-to-peer TWT agreement shall consider the non-AP STA to be in power save mode and doze state at the start of the peer-to-peer TWT SP and back to its original power management mode (i.e., the power management mode it had before entering the peer-to-peer TWT SP) at the end of the peer-to-peer TWT SP unless the AP receives a frame addressed to it from the non-AP STA within the time that overlaps with the peer-to-peer TWT SP, in which case, for the remaining portion of that peer-to-peer TWT SP, the AP shall consider the power management mode and power state of the non-AP STA based on the information carried in the frame received from the non-AP STA.

Upon receiving a Channel Usage Request frame with a TWT element configured as a TWT request and a Channel Usage element with the Usage Mode field set to 3 (Unavailability indication) that does not carry a Channel Entry field, an AP that supports peer-to-peer TWT scheduling shall transmit a Channel Usage Response frame that includes a Channel Usage element without a Channel Entry field and a TWT element configured as a TWT response (i.e., TWT Request field set to 0) with a TWT Setup Command field indicating Accept TWT and all other fields of that TWT element set to the same value as the fields of the TWT element carried in the Channel Usage Request frame. In this case, the Timeout Interval Value field of the TIE, if any, in the Channel Usage Response frame includes the same value as that of the Channel Usage Request frame.

When the Channel Usage element in a received Probe Request or Channel Usage Request frame includes one or more Operating Class/Channel Pair fields, the Operating Class/Channel Pair field(s) indicate(s) the requested non-AP STA operating class/channels for the usage mode indicated in the frame. If the Usage Mode field in the Channel Usage element carries a value that is unknown to the AP, the AP should send in the Probe Response or Channel Usage Response frame a Channel Usage element without a Channel Entry field and with a Usage Mode field value indicating Unknown request, to inform the client that the AP does not support the usage mode indicated in the request. Usage mode Unknown request shall not be used in a Probe Request frame, in a Channel Usage Request frame, or in a Channel Usage Response frame that is sent in response to a Channel Usage Request frame that includes a Channel Usage element with usage modes 0 to 3.

The AP may send an unsolicited group addressed or individually addressed Channel Usage Response frame to the STAs that have requested channel usage information if the corresponding channel usage information needs to be updated. The Country element shall be included in the unsolicited and/or group addressed Channel Usage Response frame. The AP may include the Power Constraint information and EDCA Parameter in the Channel Usage Response frame. The values of the fields in the Power Constraint and EDCA Parameter Set elements included in the Channel Usage Response frame shall be the same values of the fields in the Power Constraint and EDCA Parameter Set elements that are transmitted by the AP. If a Transmit Power Envelope element is included in the Channel Usage Response frame, the AP sets the Maximum Transmit Power Interpretation field to a value indicating a local power constraint (i.e., 0 or 1) and chooses a single set of values for the Maximum Transmit Power fields for the channel(s) specified in the Channel Usage elements.

Upon receipt of a Channel Usage element with the Channel Usage field set to 0, 1, or 2 (see Table 9-268) in the Probe Response or Channel Usage Response frame, the receiving STA may use the following:

- The channel usage information as part of channel selection processing
  - when starting a channel-usage-aidable BSS or an off-channel TDLS direct link, or

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

  - when switching the channel of an existing channel-usage-aidable BSS or off-channel TDLS direct link
- The Power Constraint element or the Transmit Power Envelope element, if present, as part of determining its maximum transmit power for transmissions for the channel-usage-aidable BSS or an off-channel TDLS direct link
- The EDCA Parameter Set element, if present, as part of determining its EDCA parameters for transmissions for the channel-usage-aidable BSS or an off-channel TDLS direct link
- The QMF Policy element, if present and dot11QMFActivated is true, as part of determining its classification of Management frames for transmissions for the channel-usage-aidable BSS or an off-channel TDLS direct link

A non-AP STA that is operating in a channel-usage-aidable BSS may send a Channel Usage Request frame with a Channel Usage element that carries a Usage Mode field with a value equal to 4 to a peer STA to indicate that it prefers to switch the operating channel of the channel-usage-aidable BSS to another channel. A non-AP STA may indicate the preferred operating channels by including one or more Operating Class And Channel fields in the Channel Entry field of the Channel Usage element carried in the corresponding Channel Usage Request frame. To provide the parameters in the HT Capabilities element, VHT Capabilities element, HE Capabilities element and/or HE 6 GHz Band Capabilities element for the preferred operating channel, the non-AP STA shall include the corresponding capabilities element(s) in the Channel Usage Request frame; otherwise, capabilities element(s) shall not be included. When the Usage Mode field indicates Channel-usage-aidable BSS channel switch request and any capabilities elements are included in the Channel Usage Request frame, the Channel Entry field shall include an Operating Class And Channel field that indicates the operating class and channel that the capability notification applies to.

Upon receiving a Channel Usage Request frame with a Channel Usage element that carries a Usage Mode field with a value equal to 4, a STA that supports channel-usage-aidable BSS channel switch requests and is operating in a channel-usage-aidable BSS should consider switching the operating channel of the channel-usage-aidable BSS to a new channel that is one of the preferred channels indicated in the received Channel Entry field of the Channel Usage element, if present. The STA shall transmit a Channel Usage Response frame in response to the reception of a Channel Usage Request frame with the Usage Mode field equal to 4 that includes a Channel Usage element with the Usage Mode field set to 4. If the channel switch request is accepted, the STA shall include the target operating class and channel in the Channel Entry field of the Channel Usage element in the Channel Usage Response frame. Otherwise, no Channel Entry field shall be included.

A STA for which dot11ChannelUsageCapabilityNotificationImplemented is true shall set the Capability Notification Support field to 1 in the Extended Capabilities elements that it transmits. A STA for which dot11ChannelUsageCapabilityNotificationImplemented is not true shall set the Capability Notification Support field to 0 in the Extended Capabilities elements that it transmits.

If an AP has the Capability Notification Support field set to 1 in the Extended Capabilities element, an associated non-AP STA for which dot11ChannelUsageCapabilityNotificationImplemented is true may send a Channel Usage Request frame with the Usage Mode field indicating Capability notification in the Channel Usage element to the AP after the non-AP STA receives an Extended Channel Switch Announcement element or an Extended Channel Switch Announcement frame from the AP. When the Usage Mode field indicates Capability notification, the Channel Entry field shall include an Operating Class And Channel field that indicates the operating class and channel that the capability notification applies to.

If an AP has the Capability Notification Support field set to 1 in the Extended Capabilities element, an associated non-AP STA for which dot11ChannelUsageCapabilityNotificationImplemented is true shall send a Channel Usage Request frame with the Usage Mode field indicating Capability notification in the Channel Usage element to the AP after the non-AP STA has received an Extended Channel Switch Announcement element or an Extended Channel Switch Announcement frame from the AP if the HT, VHT and/or HE capabilities of the STA are different before and after the channel switch except for the following cases:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The STA is a STA 5G before the channel switch and a STA 6G after the channel switch, and the only difference in the capabilities before and after the channel switch is that HT and VHT are not supported after the channel switch.
— The STA is a non-HE STA that is a STA 5G before the channel switch and a STA 2G4 after the channel switch, and the only difference in the capabilities before and after the channel switch is that VHT is not supported after the channel switch.

When an associated non-AP STA chooses to send a Channel Usage Request frame with the Usage Mode field indicating Capability notification in the Channel Usage element to the AP, the STA shall wait a random delay uniformly distributed in the range between 0 and 5000 μs, and then transmit the Channel Usage Request frame once any applicable conditions for transmitting are met (e.g., channel access procedures, DFS or enablement procedures). The Channel Usage Request frame shall be sent no later than 5 beacon periods after the expected time of the first Beacon frame in the new channel.

NOTE 9—The Channel Usage Request frame indicating Capability notification might be transmitted before or after a channel switch. In either case, the Operating Class And Channel field unambiguously identifies the channel for which the notification applies.

NOTE 10—For example, if an AP included the Max Channel Switch Time element in the frame containing the Extended Channel Switch Announcement element, then the non-AP STA cannot send a Channel Usage Request frame with the Usage Mode field indicating Capability notification to the AP if the time elapsed since the last Beacon frame in the channel prior to the channel switch is greater than $T_{MCST} + 5 \times T_{BP}$, where T_{MCST} is the switch time indicated in the Switch Time field in the Max Channel Switch Time element and T_{BP} is the beacon period.

NOTE 11—An AP knows if there are associated non-AP STAs for which dot11ChannelUsageCapabilityNotificationImplemented is false from the Capability Notification Support field in the Extended Capabilities elements transmitted by the associated non-AP STAs. How the AP determines the capabilities of the non-AP STAs for which dot11ChannelUsageCapabilityNotificationImplemented is false after a channel switch is implementation specific. For example, an AP might choose not to perform a channel switch to a different band if there are many associated non-AP STAs for which the Capability Notification Support field is 0 in the Extended Capabilities elements.

A non-AP STA that is associated to an AP shall not send a Channel Usage Request frame with the Usage Mode field indicating Capability notification in the Channel Usage element to the AP if any of the following conditions are true:

— The non-AP STA has dot11ChannelUsageCapabilityNotificationImplemented equal to false.
— The Capability Notification Support field is equal to 0 in the Extended Capabilities element transmitted by the AP.
— The non-AP STA has received neither an Extended Channel Switch Announcement element nor an Extended Channel Switch Announcement frame from the AP.

NOTE 12—If the STA has not transmitted the Channel Usage Request frame with the Usage Mode field indicating Capability notification in the Channel Usage element within a reasonable time, the AP might ignore the frame or disassociate the STA.

If a non-AP STA sends a Channel Usage Request frame with the Usage Mode field indicating Capability notification in the Channel Usage element because of channel switch from channel A to channel B, then:

— The STA shall include the HT Capabilities element if the STA supports HT in channel B even if the HT capabilities have not changed between the channels A and B.
— The STA shall include the VHT Capabilities element if the STA supports VHT in channel B even if the VHT capabilities have not changed between channels A and B.
— If channel B is in the 2.4 or 5 GHz band, the STA shall include the HE Capabilities element if the STA supports HE in the channel B even if the HE capabilities have not changed between channels A and B.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— If channel B is in the 6 GHz band, the STA shall include the HE Capabilities element and the HE 6 GHz Band Capabilities element if the STA supports HE in channel B even if the HE capabilities have not changed between the channels A and B.

If a non-AP STA transmits a Channel Usage Request frame with the Usage Mode field indicating Capability notification in the Channel Usage element during channel switch from channel A to channel B, then:

— The STA is indicating that it does not support HT in the channel B if the Channel Usage Request frame does not include the HT Capabilities element.
— The STA is indicating that it does not support VHT in the channel B if the Channel Usage Request frame does not include the VHT Capabilities element.
— The STA is indicating that it does not support HE in the channel B if the Channel Usage Request frame does not include the HE Capabilities element.

NOTE 13—Consider the case, for example, an HE non-AP STA that is a STA 6G receives from its associated AP an Extended Channel Switch Announcement element indicating a channel switch to the 2.4 GHz band. The non-AP STA sends a Channel Usage Request frame with the Usage Mode field indicating Capability notification in the Channel Usage element including only the HT Capabilities element. This means that the non-AP STA is a non-HE HT STA after the channel switch.

When the Channel Usage element is carried in a Probe Request or Probe Response frame, the Usage Mode field shall not indicate channel-usage-aidable BSS channel switch request or Capability notification.

If either a recommended operating class, or a recommended channel, or both are not supported or understood by the recipient, or if the operating country of the sender is unknown, the recipient shall discard the corresponding channel usage recommendation. A STA that has not requested channel usage information shall discard an unsolicited group addressed Channel Usage Response frame.

11.21.16 Group addressed transmission service

11.21.16.1 General

The group addressed transmission service provides delivery of group addressed frames and comprises the two services, DMS and GCR. DMG STAs do not use GCR.

11.21.16.2 DMS procedures

In this subclause, the following terms are used:

— *DMS provider*: An AP, PCP, or DMG STA associated with a PCP that provides DMS.
— *DMS recipient*: A non-AP STA that uses DMS.

In an infrastructure BSS, directed multicast service (DMS) is a service that may be provided by an AP to associated STAs that support DMS, where the AP transmits group addressed MSDUs as A-MSDUs in individually addressed MPDUs.

In a PBSS, DMS is a service that may be provided by any STA to other STAs in the same PBSS that support DMS, where the STA transmits group addressed MSDUs as A-MSDUs in individually addressed MPDUs. If the PCP of the PBSS has the PCP Forwarding field within the PCP's DMG Capabilities element set to 0, a non-PCP STA in the PBSS shall not use the PCP as a DMS provider in the PBSS.

Implementation of DMS is optional for a WNM STA and mandatory for a robust AV streaming STA (as defined in 11.25.1). A STA that implements DMS has dot11DMSImplemented equal to true. When dot11DMSImplemented is true,

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— At least one of dot11WirelessManagementImplemented and dot11RobustAVStreamingImplemented shall be true.
— dot11HighThroughputOptionImplemented shall be true for a non-DMG STA that is not a DMG or an S1G STA.

A STA with dot11DMSActivated equal to true shall support the directed multicast service and shall set to 1 the DMS field of the Extended Capabilities element that it transmits.

A DMS recipient may request use of DMS of one or more flows by sending a DMS Request frame or Reassociation Request frame that includes a DMS Request element containing one or more DMS Descriptors with the Request Type field set to "Add" per flow. Each DMS Descriptor field in the DMS Request element identifies group addressed frames that shall be transmitted to the requesting DMS recipient as individually addressed frames in addition to the group address frame transmission. In the TCLAS element, the Classifier Type subfield shall be set to the value 0, 1, or 4, and the Destination Address or Destination IP Address subfield shall be set to the multicast address of the flow that the STA requests to receive as individually addressed frames. In the TSPEC element, the STA may define the characteristics and QoS expectations of the corresponding traffic flow.

Upon receipt of a DMS Request frame or Reassociation Request frame from a DMS recipient, a DMS provider shall respond with a corresponding DMS Response frame or Reassociation Response frame. The response frame shall contain a matching (i.e., as the same DMSID) DMS Status field for each received DMS Descriptor field preserving the order present in the request frame.

NOTE 1—There is no requirement that the number of DMS Request elements and the number of DMS Response elements match. There is no requirement that the number of DMS Descriptor fields within any DMS Request element matches the number of DMS Status fields within any DMS Response element.

If a DMS provider accepts a DMS request identified by a DMS Descriptor, the Response Type field of the corresponding DMS Status field in the DMS Response element shall be set to "Accept" and a nonzero DMSID shall be assigned. If a DMS provider denies a DMS request identified by a DMS Descriptor, the Response Type field of the corresponding DMS Status field in the DMS Response element shall be set to "Denied" and the DMSID shall be set to 0. If the Response Type field is "Accept" or "Denied," then the TCLAS Elements, TCLAS Processing Element, TSPEC Element and Optional Subelements fields of a DMS Status field in a DMS Response element shall be copied from the respective TCLAS Elements, TCLAS Processing Element, TSPEC Element and Optional Subelements fields of the corresponding DMS request. When one or more STAs send a DMS request to a DMS provider, containing a DMS descriptor with a set of TCLAS element and TCLAS Processing elements that are identical irrespective of ordering to another received DMS request that is not yet terminated, the DMS provider shall assign the same DMSID as was assigned to the previous DMS request.

If a DMS provider denies the DMS Request, it may suggest an alternative TCLAS-based classifier by including one or more TCLAS elements and an optional TCLAS Processing element. The DMS provider may include fewer TCLAS elements in the DMS Response element than were present in the request; when the DMS provider's response includes a single TCLAS element, it shall not include a TCLAS Processing element. If the DMS provider changes a TCLAS element's Classifier Type field in the DMS Response element but is unable to suggest a value for the Classifier Mask field, it shall set that field to 0. If the DMS provider changes a TCLAS element's Classifier Type field or Classifier Mask field in the DMS Response element but is unable to suggest values for one or more Classifier Parameter subfields, it shall set those subfields to 0.

A DMS recipient receiving a DMS Response frame containing a modified TCLAS element having a Classifier Mask field equal to 0 or having one or more Classifier Parameter subfields equal to 0 shall interpret the values of 0 to mean that no suggested value has been provided by the DMS provider.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the requested DMS is accepted by the DMS provider, the DMS provider shall send subsequent group addressed MSDUs that match the frame classifier specified in the DMS Descriptors to the DMS recipient as A-MSDU subframes within an individually addressed MPDU that contains an A-MSDU (see 9.3.2.2 and 10.11). The A-MSDU shall be formatted as specified in 9.3.2.2 which includes the A-MSDU subframe headers' DA set to the multicast address for the corresponding MSDUs. The DMS provider shall continue to transmit the matching frames as group addressed frames (see 10.3.6, and 11.2.3.13) if at least one associated STA has not requested DMS for these frames.

A DMS recipient may request modification of the traffic characteristics or attributes of one or more accepted DMS traffic flows by sending a DMS Request frame or Reassociation Request frame that includes a DMS Request element that contains one or more DMS Descriptors each with the Request Type field set to "Change" and the DMSID field set to the DMSID of the accepted DMS traffic flows to be modified. The values of at least one of the TSPEC Element and Optional Subelement fields shall be different from those of the accepted DMS traffic flow.

If a DMS provider accepts a DMS change request identified by a DMS Descriptor, the Response Type field of the corresponding DMS Status field in the DMS Response element shall be set to "Accept" and the DMSID field shall be set to the DMSID carried in the DMS Descriptor. If a DMS provider denies a DMS change request identified by a DMS Descriptor, the Response Type field of the corresponding DMS Status field in the DMS Response element shall be set to "Denied" and the DMSID field shall be set to the DMSID carried in the DMS Descriptor. If a DMS provider denies a DMS change request identified by a DMS Descriptor, the existing DMS traffic flow of the corresponding DMSID shall remain unchanged.

A DMS recipient may request removal of one or more accepted DMS traffic flows by sending a DMS Request frame or Reassociation Request frame that includes a DMS Request element containing one or more DMS Descriptors each with the Request Type field set to "Remove" and the DMSID field set to the DMSID of the accepted DMS traffic flow to be removed. The DMS Length field shall be set to 1. The TCLAS Elements, TCLAS Processing Element TSPEC Element and Optional Subelements fields shall not be included.

A DMS provider shall terminate one or more accepted DMS traffic flows upon receipt of a DMS Request frame or Reassociation Request frame that includes a DMS Request element containing one or more DMS Descriptors each with the Request Type field equal to "Remove" and the DMSID field set to the DMSID of an accepted DMS traffic flow. The DMS provider shall respond to the termination request by sending a DMS Response frame containing one or more DMS Status fields each including the corresponding DMSID and a value of "Terminate" in the Response Type field. The DMS Length field shall be set to 3. The TCLAS Elements, TCLAS Processing Element, TSPEC Element and Optional Subelement fields shall not be included.

A DMS provider may send an unsolicited DMS Response frame at any time to terminate an accepted DMS traffic flow by including the DMSID and a value of "Terminate" in the Response Type field in the DMS Status field in a DMS Response element. A DMS provider may reject a new DMS traffic flow or terminate a granted DMS traffic flow at any time based on network condition, for example the number of associated STAs and channel load.

A DMS recipient shall keep a list of group addresses for which it has requested DMS and that have been accepted by a DMS provider and shall discard group addressed frames that match a group address in this list until the DMS has been terminated. When the DMS is terminated, and if the sequence number value is provided in the Last Sequence Control field in the DMS Response frame, using the value of the Last Sequence Control field, the DMS recipient shall discard the group addressed frames that are the duplicates of the individually addressed frames.

NOTE 2—When the Last Sequence Control field in the DMS Response frame is not supported at a DMS provider (i.e., the sequence number value is not provided in the field), and a group addressed MSDU has been sent using both individually addressed and group addressed frame transmission, termination of the DMS stream by the DMS provider might result in a DMS recipient receiving undetectable duplicate MSDUs that are not filtered out by the MAC.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the length of the DMS Descriptors exceeds 255 octets, then multiple DMS Request elements shall be included, each containing only those DMS Descriptors that are completely contained within 255 octets. If the length of the DMS status fields exceeds 255 octets, then multiple DMS Response elements shall be included, each containing only those DMS Status fields that are completely contained within the first 255 octets.

If a DMS recipient supports both DMS and FMS, it shall not request both services for the same group addressed frames simultaneously, but may request them for different group addressed frames simultaneously.

If a DMS provider supports both DMS and TFS, it shall first apply TFS to the frame and then apply DMS.

11.21.16.3 GCR procedures

11.21.16.3.1 Overview

Groupcast with retries (GCR) is a flexible service to improve the delivery of group addressed frames while optimizing for a range of criteria. GCR service may be provided by the AP to associated STAs in an infrastructure BSS or by a mesh STA to its peer mesh STAs in a mesh BSS. GCR uses the setup, modification, and termination procedures defined 11.21.16.2. The differences between GCR procedures and DMS procedures are as follows:

a) A GCR agreement applies to a single group address and, if a TCLAS Processing element is present, it has the Processing field value set to 0, whereas a DMS flow is not restricted to a single group address.
b) DMS offers group-to-individually addressed conversion only, whereas GCR includes several retransmission policies and delivery methods.

A non-DMG STA with dot11RobustAVStreamingImplemented true shall implement the GCR procedures defined in 11.21.16.3.2 to 11.21.16.3.6. When dot11RobustAVStreamingImplemented is true, dot11DMSImplemented and dot11HighThroughputOptionImplemented shall be true. A STA that implements advanced GCR supports GCR block ack (11.21.16.3.7) and GCR-SP (11.21.16.3.8) and has dot11AdvancedGCRImplemented equal to true. When dot11AdvancedGCRImplemented is true, dot11RobustAVStreamingImplemented shall be true. In a mesh BSS, a STA that implements GCR has dot11MeshGCRImplemented equal to true. When dot11MeshGCRImplemented is true, dot11HighThroughputOptionImplemented shall be true.

DMS allows the transmission of group addressed MSDUs as A-MSDUs in individually addressed MPDUs and is particularly suited to small numbers of group members. It provides a high level of reliability but has low scalability as the efficiency decreases and delay increases proportionally to the number of group members.

GCR employs the DMS Request and DMS Response elements with the addition of GCR Request and Response subelements, respectively, for administering the announcement, setup, modification, and teardown of GCR services between an AP and non-AP STAs or between peer mesh STAs. The DMS procedures and state machine of 11.21.16.2 shall apply to GCR with the extensions and constraints specific to GCR described below in 11.21.16.3.3 to 11.21.16.3.8.

Along with the No-Ack/No-Retry or non-GCR (defined in 10.3.6) and the DMS (defined in 11.21.16.2) retransmission mechanisms, GCR defines two additional retransmission policies for group addressed frames:

— GCR unsolicited retry
— GCR block ack

When using the GCR unsolicited retry retransmission policy for a group address, the STA providing GCR service retransmits an MSDU one or more times (subject to applicable retry or lifetime limits) to increase the probability of correct reception at STAs that are listening to this group address. The decision to retransmit these

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

MSDUs is implementation dependent. GCR unsolicited retry is particularly suited to use with large numbers of group members as it has moderate delay, efficiency, and reliability, but high scalability.

The GCR block ack retransmission policy extends the block acknowledgment mechanism to group addressed frames. The STA providing the GCR service initiates block ack agreements with each STA receiving GCR frames that supports GCR block ack for a particular group address. Once this block ack agreement is in place, the STA providing GCR service regularly sends BlockAckReq frames to the STAs receiving the frames to ascertain the reception status of MSDUs related to this group address, as described in 10.25.8. This allows the STA providing GCR service to discover MSDUs that have not been received and to schedule their retransmission. GCR block ack is particularly suited to use with moderate numbers of group members as it has moderate delay, high efficiency, and moderate scalability and reliability.

The GCR service has two delivery methods for group addressed frames:

— Non-GCR-SP
— GCR-SP (see 11.21.16.3.8)

The non-GCR-SP delivery method may be provided using one or more of the following:

— FMS (see 11.2.3.13)
— Transmit frames in a GCR stream after the DTIM beacon if any STA in the GCR group is in PS mode
— Transmit frames at any time if all STAs in the GCR group are in active mode in an infrastructure BSS
— In accordance with 14.15 in a mesh BSS

GCR-SP transmits GCR group addressed frames at intervals, where the interval between transmissions might be smaller than the beacon interval. Compared to non-GCR-SP, GCR-SP might provide lower delay and jitter.

GLK-GCR is a variant of GCR where the setup is implicit and is accomplished using a (Re)Association Request and Response frame exchange between the peers and termination is implicit and is accomplished when the corresponding general link is torn down. Modification is explicit and is accomplished using a GLK Groupcast Mode Change Notification frame.

GLK-GCR defines two retransmission policies for group addressed frames:

— GLK-GCR unsolicited retry
— GLK-GCR block ack

When a GLK STA implements the GLK-GCR procedures defined in 11.21.16.4.2 or 11.21.16.4.3, it shall set dot11GLKGCRImplemented to true; otherwise dot11GLKGCRImplemented shall be set to false. When dot11GLKGCRImplemented is true the GLK-GCR subfield shall be set to 1 in the Extended Capabilities element, to indicate support for GLK-GCR, otherwise the field shall be set to 0.

See 10.25.8 for the mechanisms by which GCR block ack operates.

11.21.16.3.2 GCR group membership procedures

The GCR group membership procedures do not apply to GLK-GCR. GLK-GCR uses SYNRAs.

The procedures described in 11.21.16.3.3 to 11.21.16.3.8 depend upon the AP or mesh STA knowing the membership of the multicast groups of STAs that support GCR.

One method for an AP to discover the multicast groups that its associated STAs are receiving or for a mesh STA to discover the multicast groups that its peer mesh STAs are receiving is to use the Group Membership

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Request frame (as defined in 9.6.18.4) to request the contents of the dot11GroupAddressesTable of its associated STAs or peer mesh STAs.

Other methods of group membership detection are also possible, using information that is outside the scope of this standard. For example, group membership detection could be achieved by inspecting the protocol messages of IETF RFC 3376 [B37].

An AP may transmit a Group Membership Request frame as an individually addressed frame to an associated STA that has indicated that it supports robust AV streaming (as indicated by the Robust AV Streaming bit equal to 1 in the Extended Capabilities element) to request the associated STA's dot11GroupAddressesTable. An AP shall not send a Group Membership Request frame to an associated STA that has the Robust AV Streaming bit equal to 0 in its Extended Capabilities element.

A STA for which dot11GCRActivated or dot11MeshGCRActivated is true shall reply to a Group Membership Request frame by sending a Group Membership Response frame with the Dialog Token field set to the value from the Group Membership Request frame, the Address Count field set to the number of entries in the dot11GroupAddressesTable, and the Group Address List field set to the group addresses in the dot11GroupAddressesTable. A STA for which dot11GCRActivated or dot11MeshGCRActivated is true shall set dot11GCRGroupMembershipAnnouncementActivated to true upon reception of a Group Membership Request frame.

A STA for which dot11GCRGroupMembershipAnnouncementActivated and at least one of dot11MeshGCRActivated and dot11GCRActivated are true shall send an unsolicited Group Membership Response frame with the Dialog Token field set to 0, the Address Count field set to the number of entries in the dot11GroupAddressesTable, and the Group Address List field set to the group addresses in the dot11GroupAddressesTable, every time the contents of the dot11GroupAddressesTable is modified.

If an unsolicited Group Membership Response frame is sent by an associated STA, the frame shall be transmitted as an individually addressed frame to the AP with which it is associated. If an unsolicited Group Membership Response frame is sent by a mesh station in a mesh BSS, the frame shall be transmitted as a broadcast frame.

11.21.16.3.3 GCR setup procedures

The following setup procedures apply only if the underlying link is a non-general link.

An AP with dot11GCRActivated true may transmit to an associated non-AP STA an unsolicited individually addressed DMS Response frame that contains one DMS Status field with a GCR Response subelement per group address, if it detects that the associated non-AP STA meets all of the following conditions:

- Robust AV Streaming was equal to 1 in the Extended Capabilities element in the most recently received (Re)Association Request frame from the non-AP STA.
- The non-AP STA is receiving one or more group addresses for which there is an active GCR service.
- The non-AP STA does not have a GCR agreement for one or more of these group addresses.

A mesh STA with dot11MeshGCRActivated true may transmit to a peer mesh STA an unsolicited individually addressed DMS Response frame that contains one DMS Status field with a GCR Response subelement per group address, if it detects that the peer mesh STA meets all of the following conditions:

- Mesh GCR was equal to 1 in the Extended Capabilities element in the most recently received beacon from the peer mesh STA.
- The peer mesh STA is receiving one or more group addresses for which there is an active GCR service.
- The peer mesh STA does not have a GCR agreement for one or more of these group addresses.

Each DMS Status field includes a TCLAS element to identify the GCR group address, the DMSID corresponding to this GCR traffic flow, and other associated parameters. The Status subfield of this DMS Status field shall be set to "GCR Advertise." A STA that receives this DMS Response frame from its AP may initiate a GCR agreement for one or more of the group addresses contained in the frame.

A STA requests use of the GCR service for a group address by sending a DMS Descriptor (as described in 11.21.16.2) with the following modifications:

— The DMS Descriptor shall contain one TCLAS element with the frame classifier type equal to 0 (Ethernet parameters), one TSPEC element, and one GCR Request subelement.
— In addition, the DMS Descriptor may contain other TCLAS elements.
— When there are multiple TCLAS elements, a TCLAS Processing element shall be present, and the Processing field in the TCLAS Processing element shall be set to 0. Otherwise, no TCLAS Processing elements shall be present in the DMS Descriptor.
— The TSID subfield within the TS Info field of the TSPEC element shall be reserved. Since the AP might choose a delivery method of GCR-SP, the non-AP STA should set the Minimum Service Interval, Maximum Service Interval, and Service Start Time fields in the TSPEC element to indicate the STA's preferred wakeup schedule. In a mesh BSS, the Delivery Method field shall not be set to "GCR-SP."
— The GCR Request subelement specifies the retransmission policy and delivery method requested by the non-AP STA for the group addressed stream.

A STA shall not request transmission of a group address via the GCR service while it has an active DMS for this group address. A STA shall not request transmission of a group address via DMS while it has an active GCR service for this group address.

An AP or mesh STA accepts a GCR request by sending a DMS Response frame with a DMS Response element that contains a DMS Status field with the Response Type field set to "Accept" (as described in 11.21.16.2) with the following modifications:

— The DMS Status field shall include a GCR Response subelement indicating the retransmission policy, delivery method, and GCR concealment address for the group addressed stream. The Retransmission Policy field shall not be set to "No Preference." The Delivery Method field shall not be set to "No Preference." The GCR Concealment Address field of the GCR Response subelement shall be set to dot11GCRConcealmentAddress. In a mesh BSS, the Delivery Method field shall not be set to "GCR-SP."
— If the GCR group addressed stream is subject to the GCR-SP delivery method, then the AP shall also include a Schedule element in the DMS Status field indicating the wakeup schedule for the group addressed stream.
— If a TSPEC element is included, the TSID subfield shall be set to 0.

For each GCR Request subelement, the AP or mesh STA may

— Adopt the requested retransmission policy and delivery method, or
— Maintain its existing retransmission policy and delivery method, or
— Select an alternate retransmission policy and delivery method, or
— Deny GCR service for the group addressed stream.

In an infrastructure BSS, the retransmission policy shall not be GCR block ack for a GCR group address while the AP has a GCR agreement for the group address with a non-AP STA that had the Advanced GCR field equal to 0 in the Extended Capabilities element in the (Re)Association Request frame most recently received by the AP.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In a mesh BSS, the retransmission policy shall not be GCR block ack for a GCR group address while the mesh STA has a GCR agreement for the group address with a peer mesh STA that had the Mesh GCR field equal to 0 in the Extended Capabilities element.

An AP or mesh STA denies a GCR request by sending a DMS Response frame with a DMS Response element that contains a DMS Status field with

— The Response Type field set to "Denied" (as described in 11.21.16.2), and
— An empty GCR Response subelement.

If an AP or mesh STA denies a GCR request, it may suggest an alternative TCLAS-based classifier by including one or more TCLAS elements and an optional TCLAS Processing element (as described in 9.4.2.31). One TCLAS element shall be included in the DMS Descriptor with the frame classifier type equal to 0 (Ethernet parameters). Other TCLAS elements may be included in the DMS Descriptor, but, if present, a TCLAS Processing element with the Processing field equal to 0 shall also be included.

If a STA requesting GCR service determines that one or more GCR Response subelements are unacceptable, then the STA shall discard any received ADDBA Request frames for the unacceptable GCR streams and shall send a new DMS Request frame containing a DMS Request element with one DMS Descriptor for each unacceptable GCR stream. The DMSID fields shall be set to the DMSIDs of the unacceptable streams, and the Request Type field shall be set to "Remove."

In an infrastructure BSS, if the non-AP STA accepts the response to its GCR request, the non-AP STA shall set dot11GCRConcealmentAddress to the value contained in the GCR Concealment Address field of the GCR Response subelement.

In a mesh BSS, if a STA requesting GCR service accepts the response to its GCR request, it shall add to dot11GroupAddressesTable the value contained in the GCR Concealment Address field of the GCR Response subelement.

In a mesh BSS, a GCR agreement instance is identified by a GCR agreement instance identifier. The mesh GCR agreement instance consists of the DMSID, localMAC, peerMAC, and concealment address.

For each group addressed stream requested by the non-AP STA and accepted by the AP, the AP shall immediately initiate a block ack negotiation if both of the following conditions are true:

— The AP advertised an Advanced GCR field equal to 1 in its Extended Capabilities element.
— The non-AP STA advertised an Advanced GCR field equal to 1 in the Extended Capabilities element in the (Re)Association Request frame most recently received by the AP.

For each group addressed stream requested by a mesh STA's peer (STA1), the mesh STA (STA2) receiving the request shall immediately initiate a block ack negotiation if STA2 transmitted a Mesh GCR field equal to 1 in the Extended Capabilities element in its Beacon frame and STA2 received a Beacon frame from STA1 in which the Mesh GCR field in the Extended Capabilities element is equal to 1.

If all of the above conditions are true, the AP or mesh STA shall immediately initiate a block ack negotiation by sending an ADDBA Request frame to the STA that originated the GCR request. The Block Ack Policy subfield in the Block Ack Parameter Set field within the ADDBA Request frame shall not be set to 0. The TID subfield in the Block Ack Parameter Set field within the ADDBA Request frame shall be set to 0. The A-MSDU Supported subfield within the ADDBA Request frame shall be set to 1 (A-MSDU permitted). The Starting Sequence Number field within the ADDBA Request frame shall be greater than (modulo 4096) the last sequence number of the last group address frame transmitted before the ADDBA Request frame. A STA shall maintain this block ack agreement for the duration of its GCR agreement, irrespective of whether GCR block ack is the current retransmission policy. While the retransmission policy of the GCR group addressed stream is DMS, the STA receiving GCR frames shall suspend its block ack processing for the group addressed stream.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE—Having a block ack agreement with all members of a GCR group address allows the AP or mesh STA to change the GCR retransmission policy dynamically.

For each GCR agreement, there shall be only one retransmission policy and delivery method active at any time. A GCR agreement between a non-AP STA and an AP or between peer mesh STAs shall begin when the STA providing GCR service successfully transmits an individually addressed DMS Response frame with a DMS Response element containing a DMS Status field that has the Status field set to "Accept" (as described in 11.21.16.2) with the DMS Status field including a GCR Response subelement.

11.21.16.3.4 GCR operation

The GCR operation do not apply to GLK-GCR. See 11.21.16.4.2 for GLK-GCR frame exchange procedures.

In an infrastructure BSS, a GCR block ack agreement exists between a non-AP STA and an AP for a group addressed stream from when the non-AP STA successfully transmits an ADDBA Response frame until one of the following situations occurs:

— The AP or non-AP STA successfully transmits a DELBA frame to the other party.
— The GCR agreement no longer exists.

In a mesh BSS, a GCR block ack agreement exists between a mesh STA and its peer mesh STA for a group addressed stream from the time when the mesh STA successfully transmits an ADDBA Response frame to the peer mesh STA until one of the following situations occurs:

— The mesh STA or the peer mesh STA successfully transmits a DELBA frame to the other party.
— This GCR block ack agreement expires (see 10.25.4).
— The GCR agreement is terminated.

An AP or a mesh STA may transmit a group addressed stream via the No-Ack/No-Retry (non-GCR; see 10.3.6) service and GCR service simultaneously. Each frame shall be transmitted via the No-Ack/No-Retry retransmission policy before it is transmitted via the GCR service, except when using the GCR-SP delivery method. The AP may transmit each frame via the No-Ack/No-Retry retransmission policy before or after it transmits the frame via the GCR service when using the GCR-SP delivery method. A STA providing GCR service may switch between the DMS, GCR block ack, or GCR unsolicited retry retransmission policies, but only one delivery mode may be active at any given time for each GCR group address.

An AP or mesh STA shall transmit a frame belonging to a group address via the GCR service if any associated STA or peer mesh STA has a GCR agreement for the group address and, otherwise, does not transmit the frame via the GCR service.

In an infrastructure BSS, an AP shall transmit a frame belonging to a group address via the No-Ack/No-Retry service if one or more of the following situations occur:

— The group address is the broadcast address.
— The group address is not the broadcast address, and at least one associated STA has the Robust AV Streaming bit equal to 0 in the Extended Capabilities element of the STA's most recent (Re)Association Request frame and has been determined by the AP to be a member of the group address (how this determination is made is out of the scope of this standard).
— The group address is not the broadcast address, at least one non-AP STA has a block ack agreement for the group address, and the frame precedes the start of the block ack agreement (the sequence number of the frame is less than the starting sequence number of the block ack agreement, as described in 10.25.2).

In a mesh BSS, a mesh STA providing GCR service shall transmit a frame belonging to a group address via the No-Ack/No-Retry service if one or more of the following situations occur:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— The group address is the broadcast address.
— The group address is not the broadcast address, and at least one peer mesh STA has the Mesh GCR bit equal to 0 in the Extended Capabilities element of the STA's most recent Beacon frame and has been determined to be a member of the group address (how this determination is made is out of the scope of this standard).
— The group address is not the broadcast address, at least one peer mesh STA has a block ack agreement for the group address, and the frame precedes the start of the block ack agreement (the sequence number of the frame is less than the starting sequence number of the block ack agreement, as described in 10.25.2).

When the AP updates the retransmission policy, the AP shall set the Last Sequence Control field in the GCR Response subelement to the sequence number of the MPDU corresponding to the GCR traffic flow that is being updated that was delivered prior to the change in retransmission policy.

To avoid undetected retries being passed up at a receiver's MAC SAP, duplicate detection and removal for group addressed frames is required in STAs with dot11RobustAVStreamingImplemented true or dot11MeshGCRImplemented true (see 10.3.2.14).

GCR frames shall be QoS Data frames (with QoS subfield of the Subtype subfield set to 1).

If the block ack agreement is successfully established for the group addressed stream and the delivery method for the group addressed stream is GCR-SP, then the non-AP STA is awake for subsequent SPs (see 11.21.16.3.8).

A STA may request a change of GCR service for a group addressed stream by sending a DMS Descriptor with the DMSID identifying the group address and the Request Type field set to "Change" (as described in 11.21.16.2) with the following modifications:

— The DMS Descriptor shall contain zero TCLAS elements, zero TCLAS Processing elements, one TSPEC element, and one GCR Request subelement.
— The TSPEC element and GCR Request subelement of this DMS Descriptor shall together contain at least one field that is different from the original TSPEC element and GCR Request subelement identified by the DMSID.

An AP or mesh STA may update the retransmission policy, delivery method, and schedule for any reason, such as the size of the group changes, the capabilities of the members of the group change, GCR Request subelements for the group are received, or multicast diagnostics are needed. The AP or mesh STA advertises the current settings upon a change and periodically by either of the following methods:

— Transmitting an unsolicited DMS Response frame with the current settings addressed to the GCR concealment address. This DMS Response frame shall be scheduled for delivery at the appropriate DTIM interval or SP in which all STAs within the group are awake to receive the frame. One TCLAS element shall be included with the frame classifier type equal to 0 (Ethernet parameters). Other TCLAS elements may be present, but if present, a TCLAS Processing element with the Processing field equal to 0 shall also be included. One TSPEC element and one GCR subelement shall be included per DMS Descriptor in the DMS Response element of the DMS Response frame to identify each GCR stream. The DMSID that identifies the GCR stream shall be included in the DMS Descriptor. Each Status field in the DMS Status fields included in the frame shall be set to "GCR Advertise."
— Transmitting unsolicited DMS Response frames with the current settings individually addressed to each GCR group member. Each GCR stream is identified by the DMSID in a DMS Status field in the DMS Response element of the DMS Response frame. These DMS Status fields shall not include a TCLAS element, TSPEC element, or GCR subelement. Each Status field in the DMS Status fields included in the frame shall be set to "GCR Advertise."

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA receiving GCR frames shall recover from missing group addressed DMS Response frames containing GCR Response subelements that advertise a changed retransmission policy or delivery method according to Table 11-18 or Table 11-19, respectively.

Table 11-18—STA recovery procedures for a changed retransmission policy

Current retransmission policy state at STA receiving GCR frames	Actual retransmission policy being used by the AP or mesh STA providing GCR service	Recovery procedure
GCR unsolicited retry or GCR block ack	No-Ack/No-Retry	A STA receiving GCR frames shall cancel the GCR service for the group address by sending a DMS Response frame that contains a DMS Descriptor with the Request Type field set to "Remove" when no frames for the group address are received via the GCR service after a period of dot11GCRPolicyChangeTimeout.
DMS	GCR unsolicited retry or GCR block ack	A STA receiving GCR frames shall update its current retransmission policy of the GCR stream to GCR unsolicited retry upon receiving an A-MSDU for the DMS group address concealed via the GCR concealment address.
GCR unsolicited retry or GCR block ack	DMS	A STA receiving GCR frames shall update its current retransmission policy of the GCR stream to DMS upon receiving an A-MSDU with the RA field equal to the non-AP STA's individual address and the DA field of the A-MSDU subframe equal to the GCR group address.
GCR unsolicited retry	GCR block ack	A STA receiving GCR frames shall update its current retransmission policy of the GCR stream to GCR block ack upon receiving a BlockAckReq frame with a GCR Group Address subfield equal to the GCR group address.
GCR block ack	GCR unsolicited retry	A STA receiving GCR frames shall update its current retransmission policy of the GCR stream to GCR unsolicited retry if MSDUs for the GCR group address concealed via the GCR concealment address are being received yet no BlockAckReq frames for the GCR group address are received after a period of dot11GCRPolicyChangeTimeout.

A GCR agreement between a non-AP STA and an AP or between peer mesh STAs shall end (as described in 11.21.16.2) when one of the following situations occurs:

— In an infrastructure BSS, the AP deauthenticates or disassociates the non-AP STA, or

— In a mesh BSS, the mesh STA providing GCR service tears down the peer link to the mesh STA receiving GCR frames, or

— The non-AP STA or mesh STA receiving GCR frames successfully transmits a DMS Request frame to the AP or mesh STA providing GCR service containing a DMS Request element that has a DMS Descriptor with the DMSID identifying the group addressed stream and the Request Type field set to "Remove," or

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table 11-19—Non-AP STA recovery procedures for a changed delivery method

Current delivery method state at non-AP STA	Actual delivery method being used by the AP	Recovery procedure
Non-GCR-SP	GCR-SP	A non-AP STA shall update the current delivery method state of the GCR stream to GCR-SP if a) No frames with the More Data subfield in the Frame Control field equal to 1 for the GCR stream are received for a period of dot11GCRPolicyChangeTimeout, and b) At least one frame for the GCR stream with the More Data subfield in the Frame Control field equal to 0 is received. Note that upon detecting condition a), the STA should enter the awake state in order to assist with detecting condition b).
GCR-SP	Non-GCR-SP	A non-AP STA shall update the current delivery method of the GCR stream to Non-GCR-SP if no frames with the More Data subfield in the Frame Control field equal to 0 for the GCR stream are received for a period of dot11GCRPolicyChangeTimeout and at least one frame for the GCR stream with the More Data subfield in the Frame Control field equal to 1 is received.

— The AP or a mesh STA providing GCR service successfully transmits an individually addressed DMS Response frame with a DMS Response element containing a DMS Status field with the DMSID identifying the group addressed stream that has the Response Type field set to "Terminate."

A GCR agreement between a non-AP STA and an AP or between peer mesh STAs shall end (as described in 11.21.16.2) with the following modifications:

— The DMS Status field shall include a GCR Response subelement.

— The DMS Response frame may be transmitted by an AP to the GCR concealment address or as an individually addressed frame to each STA that has an active GCR agreement for this GCR group address. The DMS Response frame shall be transmitted by a non-AP STA or mesh STA as an individually addressed frame to the STA that it has an active GCR agreement for this GCR group address.

A cancellation of a GCR agreement shall also cause the block ack agreement to be canceled for the GCR stream.

11.21.16.3.5 Concealment of GCR transmissions

The concealment of GCR transmissions does not apply to GLK-GCR.

Concealment prevents group addressed frames transmitted via the GCR unsolicited retry or GCR block ack retransmission policies from being passed up through the MAC SAPs of GCR-incapable STAs.

GCR group addressed MSDUs shall be sent in an A-MSDU when

— Retransmitted via the GCR unsolicited retry or GCR block ack retransmission policies, or

— Transmitted via the GCR-SP delivery method.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The MPDU containing this A-MSDU shall have the Address 1 field set to dot11GCRConcealmentAddress and the Retry subfield of the Frame Control field set to 1. The DA field in the A-MSDU subframe shall contain the GCR group address that is being concealed (i.e., the same value as the DA field for non-GCR group addressed delivery). One A-MSDU subframe shall be contained within one frame that contains an A-MSDU. GCR group addressed MSDUs retransmitted via the GCR unsolicited retry or GCR block ack retransmission policies shall set the Sequence Control field of the MPDU containing this A-MSDU to the same value as the Sequence Control field of the frame that contained the corresponding MSDU that was transmitted with the Retry subfield equal to 0. The first transmission attempt of a GCR group addressed MSDU transmitted via the GCR-SP delivery method shall set the Sequence Control field of the MPDU containing this A-MSDU according to the procedures defined in 10.3.2.14.

A STA with dot11RobustAVStreamingImplemented true or dot11MeshGCRImplemented true shall not use its GCR concealment address for any purpose other than the transmission of GCR streams.

A STA with dot11RobustAVStreamingImplemented true or dot11MeshGCRImplemented true and with a GCR agreement shall add the GCR concealment address from the GCR Response subelement to the STA's dot11GroupAddressesTable.

An AP with dot11RobustAVStreamingImplemented true shall not send an MSDU to the DS that has the DA field set to the GCR concealment address.

The Individual/Group Address bit (bit 0) of dot11GCRConcealmentAddress shall be set to 1.

11.21.16.3.6 GCR unsolicited retry

The GCR unsolicited retry procedures do not apply to GLK-GCR. See 11.21.16.4.3 for GLK-GCR unsolicited retry.

A STA supports the GCR unsolicited retry retransmission policy if dot11RobustAVStreamingImplemented or dot11MeshGCRImplemented is true; otherwise, the STA does not support the GCR service with retransmission policy equal to GCR unsolicited retry.

An AP or a mesh STA adopting the GCR unsolicited retry retransmission policy for a GCR group address chooses a lifetime limit for the group address. The AP or a mesh STA may vary the lifetime limit for the group address at any time and may use different lifetime limits for different GCR group addresses. An AP adopting the GCR unsolicited retry retransmission policy for a GCR group address shall transmit each MSDU according to 11.21.16.3.5, subject to the lifetime and retry limits. Transmission uses the backoff procedure described in 10.23.2.12.2.

If a block ack agreement has successfully been established for a group addressed stream that is delivered using the GCR unsolicited retry retransmission policy, the STA shall follow the duplicate detection procedures defined in 10.3.2.14.

If a block ack agreement has successfully been established for all STAs receiving a GCR group address, for a group delivered using the GCR unsolicited retry retransmission policy, the AP may retransmit any of the last *m* A-MSDUs that have the DA field in the A-MSDU subfield set to the GCR group address, where *m* is GCR buffer size (as defined in 11.21.16.3.7), subject to the lifetime limits.

If there is a STA with an active GCR agreement for a group address that does not have an active block ack agreement, the AP shall not retransmit a preceding A-MSDU for that group address. A preceding A-MDSU is defined as an A-MSDU with a sequence number value that precedes, using the modulo 2^{12} rules defined in 10.25.1, the sequence number value of the last transmitted A-MSDU for the GCR group address.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.21.16.3.7 GCR block ack

The GCR block ack procedures do not apply to GLK-GCR. See 11.24.16.4.4 for GLK-GCR block ack.

A STA supports the GCR block ack retransmission policy if dot11AdvancedGCRImplemented is true or dot11MeshGCRImplemented is true; otherwise, the STA does not support the GCR service with retransmission policy equal to GCR Block Ack.

The AP shall maintain a set of the most recently received values of the Buffer Size subfield from the Block Ack Parameter Set field in the ADDBA Response frame received from each member of a specific group address. The minimum of that set of values is defined to be the *GCR buffer size* for that group address (see 10.25.8).

11.21.16.3.8 GCR-SP

The GCR-SP delivery method does not apply to GLK-GCR.

The GCR-SP delivery method transmits GCR group addressed frames at intervals that might be smaller than the beacon interval.

A STA supports the GCR-SP delivery method if dot11AdvancedGCRImplemented is true; otherwise, the STA does not support the GCR service with the delivery method equal to GCR-SP.

NOTE—Group addressed traffic transmitted at the end of a DTIM beacon might be an impediment to providing QoS for uplink transmissions and in OBSSs. Therefore, APs in an overlapped environment are advised to make use of GCR-SP for group addressed traffic that consumes appreciable medium time.

Group addressed MSDUs shall not be transmitted via the GCR-SP delivery method policy if a non-GCR-SP delivery method is active for that group address.

All MSDUs transmitted via the GCR-SP delivery method shall be concealed using the procedures described in 11.21.16.3.5. A STA receiving group addressed MSDUs transmitted via the GCR-SP delivery method shall discard all nonconcealed MSDUs for this group address.

An AP advertises that a group addressed stream is subject to GCR-SP within a GCR Response subelement. The subelement indicates the start of each SP. See 11.2.3.5. When the Service Interval field in the Schedule element of the DMS Response frame is greater than 0, at every scheduled SP, the AP schedules for transmission buffered GCR-SP group addressed frames assigned to that particular group address.

An AP shall not establish both a GCR-SP and an FMS agreement for a group addressed stream with a single non-AP STA.

An AP may use the GCR-SP delivery method for an accepted GCR service when all of the non-AP STAs that requested the GCR service for the group address have the Robust AV Streaming bit in the Extended Capabilities element equal to 1 and the Advanced GCR bit in the Extended Capabilities element equal to 1. Otherwise, the AP shall not use the GCR-SP delivery method for the accepted GCR service.

When the Service Interval field in the Schedule element of the DMS Response frame is 0, the AP may transmit group addressed frames that are subject to this GCR agreement at any time without regard to the power state of non-AP STAs in the group. This delivery method is called *GCR-A*, where all members of the group need to stay in the awake state to receive these group addressed frames.

11.21.16.4 GLK-GCR

11.21.16.4.1 Overview

GLK-GCR functions as GCR does except as described in the subclauses below. The RA field in the MAC header corresponding to the Data frames transmitted under the GLK-GCR agreement shall contain a SYNRA.

11.21.16.4.2 GLK-GCR operation

A GLK AP that supports GLK-GCR and has set up GLK-GCR for group transmissions shall transmit group addressed frames only via the GLK-GCR mechanism. The GLK AP shall not transmit group addressed frames via the No-Ack/No-Retry (non-GCR; see 10.3.6) service as long as GLK-GCR is active. Data frames using the GLK-GCR mechanism use the non-GCR-SP delivery mode. A GLK AP providing GLK-GCR service may switch between GCR block ack, or GCR unsolicited retry retransmission policies only after indicating such a switch using the GLK Groupcast Mode Change Notification frame.

When the GLK AP updates the GLK-GCR retransmission policy, the GLK AP shall set the Last Sequence Control field in the GLK-GCR Parameter Set element to the sequence number of the MPDU corresponding to the GCR traffic flow that is being updated that was delivered prior to the change in retransmission policy.

To avoid undetected retries being passed up at a receiver's MAC SAP, GLK non-AP STAs that support GLK-GCR should detect duplicates of received group addressed frames and discard them (see 10.3.2.14).

A GLK AP may update the retransmission policy for any reason, such as a change in the size of the group or the capabilities of the members of the group The GLK AP advertises the current settings using a GLK Groupcast Mode Change Notification frame.

11.21.16.4.3 GLK-GCR unsolicited retry

A STA supports the GLK-GCR unsolicited retry retransmission policy if dot11GLKGCRImplemented is true; otherwise, the STA does not support the GLK-GCR unsolicited retry retransmission policy.

A GLK AP adopting the GLK-GCR unsolicited retry retransmission policy uses the backoff procedure described in 10.23.2.12.2.

If a block ack agreement has successfully been established for a group addressed stream that is delivered using the GLK-GCR unsolicited retry retransmission policy, the GLK STA shall follow the duplicate detection procedures defined in 10.3.2.14 and 10.25.3.

11.21.16.4.4 GLK-GCR block ack

A STA supports the GLK-GCR block ack retransmission policy if dot11GLKGCRImplemented is true; otherwise, the STA does not support the GLK-GCR block ack retransmission policy.

The Buffer Size subfield in the GLK-GCR Parameters field in the GLK-GCR Parameter Set element sent in the (Re)Association Response frame by the GLK AP is the GCR buffer size (see 10.25.8).

11.21.17 WNM notification

Implementation of the WNM notification capability is optional for a WNM STA. A STA that implements the WNM notification capability has dot11WNMNotificationImplemented equal to true. When dot11WNMNotificationImplemented is true, dot11WirelessManagementImplemented shall be true. A STA in which dot11WNMNotificationActivated is true is defined as a STA that supports WNM notification. The STA shall set to 1 the WNM Notification field of the Extended Capabilities elements that it transmits.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA that supports WNM notification reporting may send a WNM Notification Request or Response frame to a STA within the same infrastructure BSS or the same IBSS whose most recently received Extended Capabilities element contained a value of 1 for the WNM Notification field in the Extended Capabilities field; it shall not send a WNM Notification Request or Response frame otherwise.

A STA shall transmit both the WNM Notification Request frame and the WNM Notification Response frame with a destination address that is an individual address.

The WNM notification capability enables a STA to indicate management information to a peer STA:

a) Information about its firmware
b) Beacon protection failure

Use of the information provided is outside the scope of this standard. A non-AP STA that supports WNM notification and receives a WNM Notification Request frame with the Type field indicating firmware upgrade notification shall respond with a WNM Notification Response frame with the Response Status field set to 0.

11.22 WLAN interworking with external networks procedures

11.22.1 General

This subclause describes the actions and the procedures that provide interworking capabilities between IEEE 802.11 infrastructure and external networks.

11.22.2 Interworking capabilities and information

STAs indicate their support for interworking service by setting dot11InterworkingServiceActivated to true. When dot11InterworkingServiceActivated is true, STAs include the Interworking element in Beacon and Probe Response frames, and non-AP STAs include the Interworking element in Probe Request frames.

When dot11InterworkingServiceActivated and dot11ExtendedChannelSwitchActivated are both true in an infrastructure BSS, the AP may provide its operating channel and operating class to an Interworked SSPN using the values from dot11OperatingClassesTable.

In an infrastructure BSS, the Interworking element contains signaling for HeSSs. The HESSID is a MAC address that identifies the HeSS. The HESSID value shall be the universal MAC address of one of the APs in the HeSS. All BSSs in the HeSS use the same value. Thus, it is a globally unique identifier that, in conjunction with the SSID, may be used to provide network identification for an SSPN.

NOTE 1—The HESSID field in the Interworking element needs to be administered to have the same value across all BSSs in an HeSS.

NOTE 2—The concept of an HeSS is orthogonal to an ESS, and any SSIDs can be used by the BSSs that provide access to the HeSS. For more information on HeSS, refer to Wi-Fi Alliance documents [B69] and [B70].

NOTE 3—If the APs in the HeSS are using locally administered MAC addresses for their BSSIDs, the HESSID might not be any of the BSSIDs in the HeSS.

The Interworking element also provides an access network type in Beacon and Probe Response frames to assist the non-AP STA with network discovery and selection.

11.22.3 Interworking procedures: generic advertisement service (GAS)

11.22.3.1 Introduction

This subclause describes the actions and procedures that are used to invoke GAS. GAS may be used to enable network selection or service discovery for STAs when dot11InterworkingServiceActivated is true. GAS provides transport mechanisms for advertisement services while STAs are in the unassociated state as well as the associated state. This is accomplished via the use of Public Action frames, which are Class 1 frames. GAS information shall be transmitted using Public Action frames. When management frame protection is negotiated, stations shall use individually addressed Protected Dual of Public Action frames instead of Public Action frames.

A GAS frame exchange may take place between two STAs; one STA transmits a GAS query request and the other STA transmits the GAS query response as described in 11.22.3.2. The advertisement protocol transported by the GAS is one of the query protocols in Table 9-277.

A STA may transmit a group addressed GAS query request. Multiple STAs that receive a group addressed GAS query request may send an individually addressed or group addressed GAS query response.

A STA that receives multiple, similar GAS query requests from multiple STAs that require the same GAS query response may aggregate the response and transmit a group addressed GAS query response.

A STA that receives a group addressed GAS query response may process the GAS query response information without transmitting a GAS query request.

GAS shall be supported by a STA when dot11InterworkingServiceActivated is true. ANQP shall be supported by a STA when dot11InterworkingServiceActivated is true. Other advertisement protocols shall be supported when the corresponding dot11GASAdvertisementID is present.

GAS query request fragmentation shall be supported by a STA when dot11GASQueryRequestFragmentationActivated is true.

A STA shall not transmit a GAS query request for any advertisement protocol unless that advertisement protocol ID is included in the Advertisement Protocol element in a Beacon or Probe Response frame. The Advertisement Protocol element specifies the advertisement protocols that a STA may use to communicate with advertisement servers, which may be colocated with a STA or in an external network. The advertisement protocol identifies the query language used by the advertisement server. The GAS protocol, which is used to transport GAS query requests and GAS query responses, is transparent to the advertisement protocol.

11.22.3.2 GAS Protocol

11.22.3.2.1 General

The presence of the Interworking element in Beacon or Probe Response frames indicates support for the GAS protocol. The additional presence of the GAS Extension element with the Group Addressed GAS subfield in the GAS Extension element set to true in a GAS Initial Request frame or group addressed GAS frames indicates support for the use of group addressed GAS frames. The presence of the Advertisement Protocol element in Beacon or Probe Response frames indicates the advertisement protocol IDs supported in the BSS or IBSS.

A STA transmits a GAS query request in either a GAS Initial Request, GAS Comeback Request, GAS Comeback Request Fragment or Group Addressed GAS Request frame and the responding STA provides a GAS query response or information on how to receive the GAS query response in a GAS Initial Response, GAS Comeback Response or Group Addressed GAS Response frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The GAS query request or GAS query response shall be delivered in a single GAS Initial Request or GAS Initial Response frame, in a Group Addressed GAS Request or Group Addressed GAS Response frame, or in one or more GAS Comeback Request, GAS Comeback Request Fragment or GAS Comeback Response frames. The GAS Initial Request or Response frame shall not include a fragment.

The GAS message sequence diagrams are shown in Figure 11-77 , Figure 11-78 , Figure 11-79 , Figure 11-81 , Figure 11-80 , Figure 11-82 , Figure 11-76 , and Figure 11-83 .

Figure 11-76 describes the GAS frame exchange when the GAS query request is too large to fit in one MMPDU and GAS fragmentation is used for delivery. The number of GAS Comeback Request Fragment and GAS Comeback Response frames depends on the number of GAS fragments required for delivery of the GAS query request.

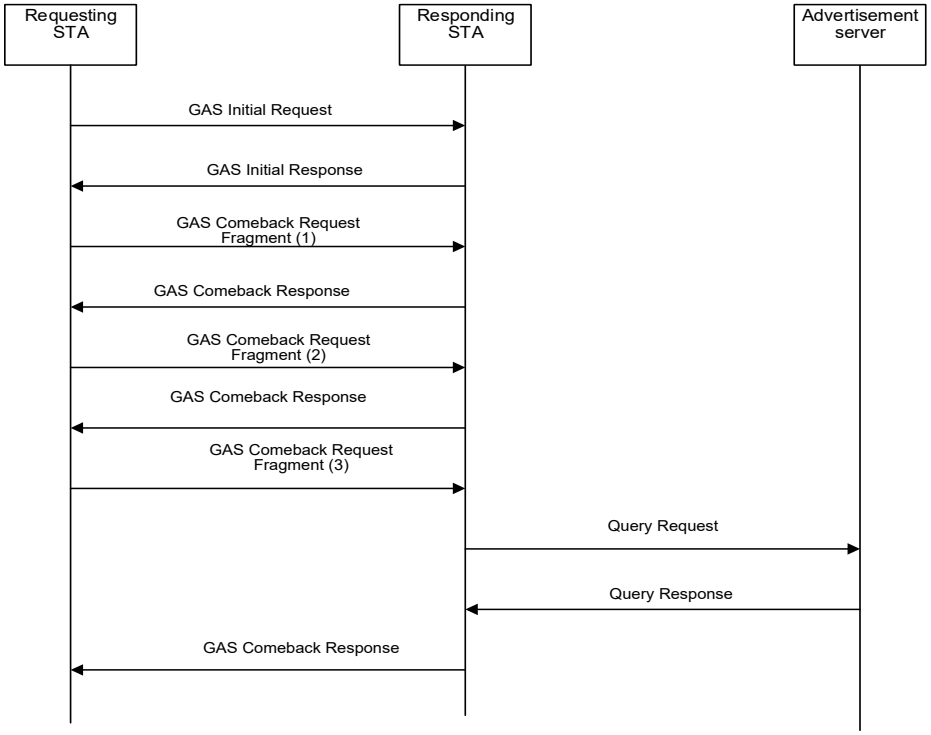

Figure 11-76—GAS frame exchange with query request fragmentation

If a GAS Initial Request frame or a Group Addressed GAS Request frame contains a Maximum Channel Time field in the GAS Extension Element and if the conditions for replying as described in 11.22.3.2.4 and 11.22.3.2.5 are met, the responding STA shall queue for transmission a GAS Initial Response frame or a Group Addressed GAS Response frame within the indicated Maximum Channel Time.

Figure 11-77 describes the GAS frame exchange when dot11GASPauseForServerResponse is true and the result of the GAS query request fits within one MMPDU.

Figure 11-78 describes the GAS frame exchange when a STA sends a Group Addressed GAS Request frame to a group of STAs. The receiving STA may respond to the GAS query request. If the receiving STA responds, it may respond with either a GAS Initial Response frame or a Group Addressed GAS Response frame.

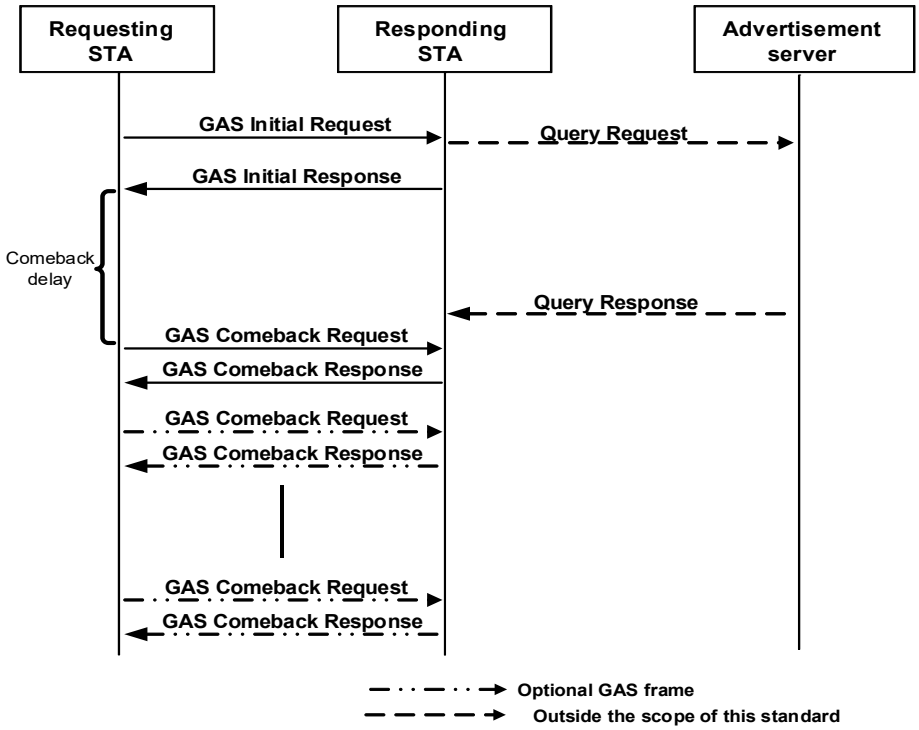

Figure 11-81—GAS frame exchange with GAS fragmentation and dot11GASPauseForServerResponse equal to false

Figure 11-82 describes the GAS frame exchange when a STA issues a GAS Initial Request frame and, during the course of receiving a fragmented GAS Comeback Response frame, requests a specific fragment for retransmission from the transmitting STA.

Figure 11-83 describes a GAS frame exchange using CAG Version when a requesting STA requests information that the requesting STA has a cached version of a previous query response and the associated Common Advertisement Group (CAG) Version. The requesting STA provides its cached CAG Version in a GAS Initial Request frame along with the query request. When the responding STA determines that the CAG Version cached by the requesting STA matches a valid CAG Version that the responding STA receives from a relevant advertisement server as indicated by the CAG Information Type, which is provided by the requesting STA in the same CAG Tuple field that contains the cached CAG Version, then the responding STA provides a GAS response indicating that the information cached by the requesting STA is still valid. When the responding STA determines that the CAG Version cached by the requesting STA does not match any valid CAG Version that the responding STA receives from a relevant advertisement server as indicated by the CAG Information Type, which is provided by the requesting STA in the same CAG Tuple field that contains the cached CAG Version, then the responding STA posts the query request to the relevant advertisement server as specified in 11.22.3.2.4, receives a query response from the advertisement server, and transmits the query response to the requesting STA as specified in 11.22.3.2.5.

11.22.3.2.2 STA procedures to transmit a GAS query request

Upon receipt of an MLME-GAS.request primitive, the requesting STA shall engage in the following procedure to transmit a query:

a) If GAMode in the primitive is null or set to false, the requesting STA sends a GAS query request by transmitting a GAS Initial Request frame containing a Dialog Token field, an Advertisement Protocol element containing an Advertisement Protocol ID field and GAS query request in the Query Request field. If the GAS Initial Request frame requests information relating to a frequency band different from the frequency band in which the frame is transmitted, the STA shall include a Multi-band element in the GAS Initial Request frame with the Band ID, Operating Class, and Channel Number fields set to indicate to which frequency band the GAS Initial Request frame applies, with other fields in the Multi-band element being reserved. If the frame requests information relating to the frequency band in which the frame is transmitted, a Multi-band element shall not be included in the frame. If the GAS Initial Request frame requests information that the requesting STA has a cached version of a previous query response and the associated CAG Version, the requesting STA may include the cached CAG Version and the associated CAG Information Type in a CAG Number element in the GAS Initial Request frame. If GAMode in the primitive is(M118) true, the requesting STA transmits a Group Addressed GAS Request frame including a GAS Extensions element with the Maximum Channel Time field set to the value of the dot11GASResponseTimeout divided by 10, rounded to the nearest integer, and limited to a value of 255. The GAS protocol supports query requests whose length is greater than the maximum MMPDU size by the STA's use of the GAS Query Fragment ID field in a GAS Comeback Request Fragment frame, subsequent to a GAS Initial Request frame. The GAS Query Fragment ID shall be set to 0 for the initial fragment and incremented by 1 for each subsequent fragment in a multi-fragment query request. The STA shall transmit all fragments that belong to the same query request until all fragments are exhausted. The STA shall set the More GAS Fragments field of the GAS Query Fragment ID to 0 when the transmitted fragment is the final fragment.

b) Upon transmission of the GAS Initial Request, Group Addressed GAS Request or GAS Comeback Request Fragment frame, the STA shall set a timer, referred to as the *dot11GASResponseTimer*, equal to dot11GASResponseTimeout or the QueryFailureTimeout parameter provided in the MLME-GAS.request primitive. If both values are present, the timer shall be set to the lesser of the two values.

c) If the requesting STA is not in the associated state, it shall remain in active mode until the receipt of a GAS Initial Response, Group Addressed GAS Response or GAS Comeback Response frame with the same value of the Dialog Token field as in the GAS Initial Request frame or until the expiration of the timer, whichever occurs first. If the requesting STA is in the associated state, it may go into power save state until the GAS Initial Response, Group Addressed GAS Response or GAS Comeback Response frame, is available for receipt or the timer expiration, whichever occurs first.

d) If the dot11GASResponseTimer expires before a GAS Initial Response, Group Addressed GAS Response or GAS Comeback Response frame is received, the GAS query request was not successful and the MLME shall issue an MLME-GAS.confirm primitive with the ResultCode field set to GAS_QUERY_TIMEOUT and shall set the Query Response Length field to 0.

11.22.3.2.3 STA procedures for GAS query request fragmentation

The Fragment ID field in the GAS Extension element, when present in a GAS Initial Request frame, indicates that the query request will be transmitted using GAS Comeback Request Fragment and GAS Comeback Response frames that support GAS fragmentation.

If a GAS Query Fragment ID field is present in a GAS Comeback Request Fragment frame the receiving STA shall buffer the query request for a minimum of dot11GASRequestBufferingTime or until the GAS query request is delivered. If the receiving STA does not receive a GAS Comeback Request Fragment frame whose source address and dialog token match the source address and value of the Dialog Token field respectively of

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the corresponding GAS Initial Response frame within this time, it may discard the query request. If the query request received from the requesting STA, is larger than dot11GASQueryRequestLengthLimit for the matching dot11GASAdvertisementID or is larger than the value of the Query Request Length Limit field received from the requesting STA, the responding STA shall discard the request and instead return a status code of GAS_QUERY_REQUEST_TOO_LARGE in the GAS Comeback Response frame. This behavior helps to prevent abuses of the medium that may be caused by an overly large GAS query request.

If the GAS query request received from the requesting STA is greater than the maximum MMPDU size, then the GAS Query Fragment ID shall be set to 0 if this is the first fragment of the query request transmitted; otherwise it shall be incremented by 1; the More GAS Fragments field in the GAS Query Fragment ID shall be set to 1 if there are more fragments of the query request to be transmitted; otherwise it shall be set to 0 (i.e., this fragment is the last fragment of the query request). If a requesting STA receives a GAS Comeback Response that includes the GAS Extension element with the Fragment ID field set to a valid Fragment ID the requesting STA shall transmit a GAS Comeback Request Fragment frame that includes the fragment corresponding to the received Fragment ID.

If the responding STA supports the GAS extension, and the responding STA is unable to receive a GAS query request fragment, then the following procedures apply:

a) If the Fragment Retransmission subfield in the GAS Extension element in the corresponding GAS Initial Request frame is equal to 1, the responding STA may transmit a GAS Comeback Response frame, including the GAS Extension element with the Fragment ID subfield of the GAS Flags field set to the fragment ID of the query request to be retransmitted. Upon receiving the GAS Comeback Response, the requesting STA shall transmit a GAS Comeback Request Fragment frame that includes the query request fragment corresponding to the value received in the Fragment ID field and with the GAS Query Fragment ID subfield in the GAS Comeback Request Fragment frame set to the value received in the Fragment ID field. If the Query Request fragment is not available, the requesting STA shall respond with a GAS Comeback Request Fragment frame with a status code set to GAS_FRAGMENT_NOT_AVAILABLE.

b) If the corresponding GAS Initial Request frame does not contain a GAS Extension element or the Fragment Retransmission subfield in the GAS Extension element is equal to 0, the responding STA shall not request the retransmission of a query request fragment using a GAS Comeback Response frame.

If a responding STA receives a GAS Comeback Request Fragment frame with status equal to SUCCESS and the More GAS Fragments field in the GAS Query Fragment ID equal to:

- 1, it shall transmit another GAS Comeback Response frame in order to retrieve the next GAS fragment of a multi-fragment query request.

- 0, the responding STA's MLME shall determine that all fragments have been received by confirming that all fragment IDs from 0 to the value in the GAS Query Fragment ID when the More GAS Fragments field was equal to 0 have been received. Upon receipt of the first GAS Comeback Request Fragment frame and every GAS Comeback Request Fragment frame thereafter, the dot11GASRequestTimer shall be reset.

If all of the query request fragments were received before the expiration of the dot11GASRequestTimer, then the MLME shall issue an MLME-GAS.confirm primitive with result code set to SUCCESS along with the query request.

If not all of the query request fragments were received before the expiration of the dot11GASRequestTimer, then the MLME shall issue an MLME-GAS.confirm primitive with the ResultCode field set to GAS_QUERY_TIMEOUT and shall set the Query Request Length field to 0.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If a requesting STA receives a GAS Comeback Request frame with a Status Code field equal to either: GAS_QUERY_REQUEST_TOO_ LARGE then the MLME shall issue an MLME-GAS.confirm primitive with the ResultCode field set to the value of the Status Code field and shall set the Query Request Length field to 0.

After a responding STA receives the first GAS fragment of a multi-fragment query request, it shall continue retrieving the query request until all GAS fragments are received or until a transmission failure is detected; the responding STA shall not commence the reception of another query request from the same STA until all GAS fragments are received or until a transmission failure is detected on the first quest request.

11.22.3.2.4 STA procedures to post a GAS query request to an advertisement server

Upon receipt of a GAS Initial Request, Group Addressed GAS Request or GAS Comeback Request Fragment frame, an MLME-GAS.indication primitive shall be issued to the STA's SME. Upon receipt of an MLME-GAS.indication primitive indicating the receipt of a GAS Initial Request, Group Addressed GAS Request or GAS Comeback Request Fragment frame, the STA shall transmit a GAS Initial Response, Group Addressed GAS Response or GAS Comeback Response frame to the requesting STA according to the following procedures. If the requesting STA is in the associated state and in the power save mode, the responding STA shall buffer the MMPDU for transmission according to the procedures in 11.2.3; otherwise the STA shall queue the MMPDU for transmission as follows:

a) If the Advertisement Protocol ID field in the Advertisement Protocol element does not equal the value contained in any dot11GASAdvertisementID, then the STA shall not post the query request to an advertisement server. The STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code field equal to GAS_ADVERTISEMENT_PROTOCOL_NOT_SUPPORTED (see Table 9-80), an Advertisement Protocol element containing the Advertisement Protocol ID field used in the GAS Initial Request frame and GAS Comeback Delay and Query Response Length fields both set to 0.

b) If the query request corresponds to an advertisement protocol whose server is currently unreachable, the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code equal to SERVER_UNREACHABLE, an Advertisement Protocol element containing an Advertisement Protocol ID field equal to the advertisement protocol ID contained in the GAS Initial Request frame and GAS Comeback Delay and Query Response Length fields both set to 0. The method used by the AP to determine the server is unreachable is out of scope of this standard. A STA receiving a status code indicating SERVER_UNREACHABLE should wait at least 1 minute before transmitting any further queries using the same advertisement protocol ID to the responding STA.

c) If the GAS Initial Request frame includes a CAG Number element and all the CAG Versions in the CAG Number element match a valid CAG Version that the STA receives from the associated advertisement server, which is identified by the CAG Information Type subfield within the same CAG Tuple field as the CAG Version subfield, then the STA may transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code equal to SUCCESS_CAG_VERSIONS_MATCH, an Advertisement Protocol element containing the Advertisement Protocol ID field used in the GAS Initial Request frame, and GAS Comeback Delay and Query Response Length fields both set to 0, without posting the query to an advertisement server. This completes the GAS query request and GAS query response exchange.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

d) If the Advertisement Protocol ID field in the Advertisement Protocol element equals the value contained in any dot11GASAdvertisementID, then the STA shall initialize a timer, referred to as the *PostReplyTimer*, to the value of the Maximum Channel Time field times 10, if received in the GAS Initial Request or Group Addressed GAS Request frame, or otherwise, to the value in dot11GASResponseTimeout. The STA posts the query to the advertisement server identified by the advertisement protocol ID.

e) If the GAMode associated with the Query Request is true, the STA includes the GAMode parameter, the GAS extension information, the MAC Address, and the Dialog token when it posts the query to the advertisement server for processing. The methods and protocols the STA uses to post the query are outside the scope of this standard.

   1) If the GAMode associated with the Query Request is true and the advertisement server has no response to the Query Request, the advertisement server may ignore the request.

   2) If the advertisement server receives multiple GAS query requests resulting in the same response, the advertisement server may aggregate these responses into a single GAS query response. The advertisement server responds to the STA including the aggregated responses as described in 11.22.3.2.6.

f) If dot11GASPauseForServerResponse is false, the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code field set to SUCCESS, an Advertisement Protocol element containing the Advertisement Protocol ID field used in the GAS Initial Request frame, a GAS Comeback Delay field set to the value in dot11GASComebackDelay for this advertisement protocol and a Query Response Length field set to 0.

g) If dot11GASPauseForServerResponse is true, the GAS query response is delivered as defined in 11.22.3.2.5.

11.22.3.2.5 STA procedures for transmitting the GAS query response

After receiving a query response from the advertisement server, the responding STA shall buffer the query response for a minimum of dot11GASResponseBufferingTime after the expiration of the GAS comeback delay timer or until the query response is delivered. If the responding STA does not receive a GAS Comeback Request frame whose source MAC address and dialog token match the source MAC address and value of the Dialog Token field respectively of the corresponding GAS Initial Response frame within this time, it may discard the query response. If the query response received from the advertisement server is larger than dot11GASQueryResponseLengthLimit for the matching dot11GASAdvertisementID or is larger than the value of the Query Response Length Limit field received from the requesting STA, the responding STA shall discard the response and instead return a status code of GAS_QUERY_RESPONSE_TOO_ LARGE in the GAS Comeback Response frame. This behavior helps to prevent abuses of the medium that may be caused by overly general queries, which evoke a very large query response.

The GAS protocol supports Query Responses whose length is greater than the IEEE 802.11 maximum MMPDU size by the responding STA's use of the GAS Query Fragment ID field in the GAS Comeback Response frame; the GAS Query Fragment ID shall be set to 0 for the initial fragment and incremented by 1 for each subsequent fragment in a multi-fragment query response. If the GAS query response is a multi-fragment response (i.e., contains more than 1 fragment), the STA shall transmit all fragments that belong to the same Query Response until all fragments are exhausted. The STA shall set the More GAS Fragments field of the GAS Query Fragment ID to 0 when the transmitted fragment is the final fragment.

If the GAS Initial Request frame that initiated the GAS transaction contains a Multi-band element, but the GAS Initial Response frame transmitted as a response does not contain a copy of the same Multi-band element, the status code in the GAS Initial Response frame shall be set to REQUEST_DECLINED. Otherwise, the requesting and responding STAs shall include a copy of the same Multi-band element in all subsequent GAS

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Initial Response, GAS Comeback Request, and GAS Comeback Response frames transmitted as part of the GAS transaction. Inclusion of the Multi-band element indicates to which frequency band the GAS transaction applies. If the GAS Initial Request frame that initiated the GAS transaction does not contain a Multi-band element, then none of the subsequent GAS Initial Response, GAS Comeback Request, and GAS Comeback Response frames transmitted as part of the GAS transaction shall include a Multi-band element.

The following procedures shall be used by the responding STA to deliver the query response to the requesting STA:

a) If dot11GASPauseForServerResponse is true:
   1) If the query response is received from the advertisement server before the PostReplyTimer expires, and if the query response's length is less than or equal to the maximum MMPDU size and the query response is not an aggregated response, the STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, the Status Code field set to SUCCESS, an Advertisement Protocol element containing the Advertisement Protocol ID field used in the GAS Initial Request frame or the Group Addressed Request frame, a GAS Comeback Delay field set to 0, a Query Response field and a Query Response Length field set to the query response length. This completes the GAS request and response exchange.
   2) If the query response is received from the advertisement server before the PostReplyTimer expires, and if the query response's length is less than or equal to the maximum MMPDU size and the query response is an aggregated response, the STA shall transmit a Group Addressed GAS Response frame containing a dialog token set to 0, the Status Code field set to SUCCESS, an Advertisement Protocol element containing the Advertisement Protocol ID field used in the GAS Initial Request frame or the Group Addressed Request frame, a GAS Comeback Delay field set to 0, a Query Response field and a Query Response Length field set to the query response length, and a GAS Extension element containing a list of MAC Address/Dialog Token pairs in the Response Map Duples subfield of the GAS Extension element, identifying the requesting STAs and their Query Requests to which the Group Addressed GAS Response frame responds. This completes the GAS query request and GAS query response frame exchange.
   3) If the PostReplyTimer expires before the query response is received from the advertisement server for responding to a GAS Initial Request frame, then the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code field set to GAS_QUERY_TIMEOUT (see Table 9-80), an Advertisement Protocol element containing the Advertisement Protocol ID field used in the GAS Initial Request frame, and GAS Comeback Delay and Query Response Length fields both set to 0. If the query response is subsequently received from the advertisement server, it shall be ignored by the responding STA.
   4) If the PostReplyTimer expires before the query response is received from the advertisement server for responding to a Group Addressed GAS Request frame, then the responding STA shall not transmit an individually addressed GAS Initial Response frame or a Group Addressed GAS Response frame to the requesting STA.

      NOTE—If there is no response to the Query Request, the advertisement server may ignore the request.

   5) If the Query Response received from the advertisement server is larger than dot11GASQueryResponseLengthLimit or requires more than 128 fragments for transmission to the requesting STA, it shall be ignored by the responding STA. Then the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code field set to GAS_QUERY_RESPONSE_TOO_ LARGE (see Table 9-80), an Advertisement Protocol element containing the Advertisement Protocol ID

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

field used in the GAS Initial Request frame, and GAS Comeback Delay and Query Response Length fields both set to 0.

6) If the query response's length is larger than the maximum MMPDU size, the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code field set to SUCCESS, an Advertisement Protocol element containing the Advertisement Protocol ID field used in the GAS Initial Request frame, a GAS Comeback Delay field set to 1 (TU), and a Query Response Length field set to 0; this indicates the query response will be transmitted using GAS Comeback Request and Response frames that support GAS fragmentation as follows. If the responding STA is capable of retransmitting a Query Response fragment upon request, the responding STA shall include, in the GAS Initial Response frame, a GAS Extension element with the Fragment Retransmission subfield of the GAS Flags field set to 1.

b) If dot11GASPauseForServerResponse is false:

1) If the PostReplyTimer expires before the GAS query response is received from the advertisement server then the responding STA shall buffer for transmission a GAS Comeback Response frame with a Status Code field set to GAS_QUERY_TIMEOUT (see Table 9-80). If the query response is subsequently received from the advertisement server, it shall be ignored by the STA.

2) If the Query Response received from the advertisement server is larger than dot11GASQueryResponseLengthLimit, it shall be ignored by the responding STA. Then the STA shall buffer for transmission a GAS Comeback Response frame with status code set to GAS_QUERY_RESPONSE_TOO_ LARGE.

c) If the Query Response is received before the expiration of the PostReplyTimer and its length is less than dot11GASQueryResponseLengthLimit, then the Query Response shall be buffered in one or more GAS Comeback Response frames with status code set to SUCCESS. The responding STA transmits one GAS Comeback Response frame in response to each GAS Comeback Request frame. If the Query Response received from the advertisement server is less than or equal to the maximum MMPDU size, then the GAS Query Fragment ID shall be set to 0 and the More GAS Fragments field in the GAS Query Fragment ID shall be set to 0. If the Query Response received from the advertisement server is greater than the maximum MMPDU size, then the GAS Query Fragment ID shall be set to 0 if this is the first fragment of the Query Response transmitted; otherwise it shall be incremented by 1; the More GAS Fragments field in the GAS Query Fragment ID shall be set to 1 if there are more fragments of the Query Response to be transmitted; otherwise it shall be set to 0 (i.e., this fragment is the last fragment of the Query Response). If a responding STA receives a GAS Comeback Request that includes the GAS Extension element with the Fragment ID field set to a valid Fragment ID the responding STA shall respond with a GAS Comeback Response frame that includes the fragment corresponding to the received Fragment ID.

d) If a responding STA receives a GAS Comeback Request frame whose source MAC address and dialog token match the destination MAC address and value of the Dialog Token field respectively of an outstanding GAS Initial Response frame and the query response has not been received from the advertisement server and the PostReplyTimer has not expired, the responding STA shall transmit a GAS Comeback Response frame with a Status Code field set to GAS_RESPONSE_NOT_RECEIVED_FROM_SERVER (see Table 9-80) and a GAS Comeback Delay field set to the value in dot11GASComebackDelay for this advertisement protocol to indicate when the requesting STA should come back to obtain its Query Response.

e) If a responding STA receives a GAS Comeback Request frame whose source MAC address and Dialog Token do not match the destination MAC address and value of the Dialog Token field respectively of an outstanding GAS Initial Response frame, the STA should transmit a GAS Comeback Response frame with a status code equal to NO_OUTSTANDING_GAS_REQUEST.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A requesting STA shall transmit a GAS Comeback Request frame including the Dialog Token (drawn from the corresponding GAS Initial Response frame) immediately after the expiration of the GAS Comeback Delay. In response, the responding STA provides the Query Response in one or more GAS Comeback Response frames with the corresponding Dialog Token.

If the requesting STA supports the GAS extension, and the requesting STA is unable to receive a GAS query response fragment, then the following procedures apply:

a) If the Fragment Retransmission subfield in the GAS Extension element in the corresponding GAS Initial Response frame is equal to 1, the requesting STA may transmit a GAS Comeback Request frame, including the GAS Extension element with the Fragment ID subfield of the GAS Flags field set to the fragment ID of the Query Response to be retransmitted. Upon receiving the GAS Comeback Request frame, the responding STA shall transmit a GAS Comeback Response frame that includes the Query Response fragment corresponding to the value received in the Fragment ID field and with the GAS Query Fragment ID subfield in GAS Query Fragment field set to the value received in the Fragment ID field. If the Query Response fragment is not available, the responding STA shall respond with a GAS Comeback Response frame with a status code set to GAS_FRAGMENT_NOT_AVAILABLE.

b) If the corresponding GAS Initial Response frame does not contain a GAS Extension element or the Fragment Retransmission subfield in the GAS Extension element is equal to 0, the requesting STA shall not request the retransmission of a GAS query response fragment using a GAS Comeback Request frame.

If a requesting STA receives a GAS Comeback Response frame with status equal to QUERY_RESPONSE_OUTSTANDING, the requesting STA shall wait for the expiration of the GAS comeback delay timer from that frame and then, transmit another GAS Comeback Request frame. If the requesting STA's dot11GASResponseTimer (set in 11.22.3.2.2 step b) expires prior to receiving a GAS Comeback Response frame whose source MAC address and dialog token match those in the corresponding GAS Initial Response frame, the STA shall issue an MLME-GAS.confirm primitive with the ResultCode filed set to GAS_QUERY_TIMEOUT and shall set the Query Response Length field to 0.

If a requesting STA receives a GAS Comeback Response frame with status equal to SUCCESS and the More GAS Fragments field in the GAS Query Response Fragment ID equal to

— 1, it shall transmit another GAS Comeback Request frame in order to retrieve the next GAS fragment of a multi-fragment query response.

— 0, the requesting STA's MLME shall determine that all fragments have been received by confirming that all fragment IDs from 0 to the value in the GAS Query Fragment ID when the More GAS Fragments field was equal to 0 have been received. Upon receipt of the first GAS Comeback Response frame and every GAS Comeback Response frame thereafter, the dot11GASResponseTimer shall be reset. If all of the query response fragments were received before the expiration of the dot11GASResponseTimer, then the MLME shall issue an MLME-GAS.confirm primitive with result code set to SUCCESS along with the query response. If not all of the query response fragments were received before the expiration of the dot11GASResponseTimer, then the MLME shall issue an MLME-GAS.confirm primitive with the ResultCode field set to GAS_QUERY_TIMEOUT and shall set the Query Response Length field to 0.

After a requesting STA receives the first GAS fragment of a multi-fragment query response, it shall continue retrieving the query response until all GAS fragments are received or until a transmission failure is detected; the requesting STA shall not commence the retrieval of another GAS query response from the same STA until all GAS fragments are received or until a transmission failure is detected on the first GAS query response.

If a requesting STA receives a GAS Comeback Response frame with a Status Code field equal to either: GAS_QUERY_TIMEOUT, GAS_QUERY_RESPONSE_TOO_ LARGE or NO_OUTSTANDING_GAS_REQUEST, then the MLME shall issue an MLME-GAS.confirm primitive with

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the ResultCode field set to the value of the Status Code field and shall set the Query Response Length field to 0.

11.22.3.2.6 Group addressed GAS procedures

Upon receipt of an MLME-GAS.request primitive with the GAMode parameter set to 1 (true), the requesting STA shall follow procedures defined in 11.22.3.2.2 to transmit a Group Addressed GAS Request frame instead of a GAS Initial Request frame.

Upon receipt of an aggregated Query Response from the advertisement server, the responding STA may transmit the aggregated Query responses using Group Addressed GAS Response frame to the receiving STAs. The length of the Group Addressed GAS Response frame shall not exceed the IEEE 802.11 maximum MMPDU size. The STA shall include a list of MAC Address/Dialog Token pairs in the Response Map Duples subfield of the GAS Extension element included in the Group Addressed GAS Response frame.

11.22.3.2.7 GAS procedures interaction with multiple BSSID set

Non-AP STAs in the unassociated state may use GAS procedures to query advertisement servers for information. As described in 11.22.3.2, APs indicate their support for a particular GAS advertisement protocol by including an Advertisement Protocol element with that advertisement protocol ID in Beacon and Probe Response frames as described in 9.3.3.2 and 9.3.3.10 respectively. Non-AP STAs receiving Beacon or Probe Response frames from different APs may choose to engage in GAS frame exchange with one or more of these APs. In some deployment scenarios, these APs may be operating as a multiple BSSID set (as defined in 11.10.14) and may relay the GAS queries to the same advertisement server. Depending on the configuration of the IEEE 802.11 access network, the external network and the advertisement server, a query response from the advertisement server might or might not be dependent on the BSSID used in the GAS frame exchange and thus the STA from which the query was relayed. If the GAS query response is dependent on the BSSID, a requesting STA may choose to post queries using GAS procedures to more than one STA and expect possibly different Query Responses. If the Query Response is not dependent on the BSSID, then a requesting STA may choose to post queries using GAS procedures to only one STA in the multiple BSSID set (i.e., posting the same query to another member of the multiple BSSID set would yield the same response).

When a Multiple BSSID (as defined in 11.10.14) set contains two or more members and dot11InterworkingServiceActivated is true and dot11GASAdvertisementID is present and a query to the advertisement server corresponding to dot11GASAdvertisementID is not dependent on the BSSID used in the GAS frame exchange to post the query, then the PAME-BI bit in the Advertisement Protocol tuple of the Advertisement Protocol element corresponding to dot11GASAdvertisementID shall be set to 1; otherwise this bit shall be set to 0.

11.22.3.3 ANQP procedures

11.22.3.3.1 General

A STA may use ANQP to retrieve information as defined in Table 9-426 from a peer STA.

A non-AP STA shall not transmit an ANQP request to an AP for any ANQP-element unless the ANQP Advertisement Protocol ID field is included in the Advertisement Protocol element in a Beacon or Probe Response frame from that AP.

A STA shall unless specified otherwise ignore an ANQP request or response that contains non-reserved field/ subfield values that are not known to it.

The ANQP request consists of one or more ANQP-elements drawn from Table 9-426 having an element type of Q in Table 11-20 and shall be ordered by nondecreasing Info ID. A Query List ANQP-element included in

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

an ANQP request is formed as described in 11.22.3.2.2. The ANQP request is transported in the Query Request field of Group Addressed GAS Request frames as described in 11.22.3.2.5.

The ANQP response is transported in the Query Response field of GAS Response frames. The AP should include in the ANQP response the ANQP-elements requested by the non-AP STA (in the Query List ANQP-element of the ANQP request) that are available at the AP, using the procedure described in 11.22.3.2.5. The AP should provide the ANQP-elements requested by the non-AP STA that are not available at the AP at the time of the request but can be obtained by the AP from an advertisement server, using the comeback procedure described in 11.22.3.2. The AP shall not include an ANQP-element in the ANQP response that was not requested by the non-AP STA. ANQP-elements in the ANQP response shall have an ANQP-element type of S in Table 11-20 and shall be ordered by nondecreasing Info ID. The non-AP STA may interpret ANQP-elements in any order. The interpretation of ANQP-elements whose semantics overlap is implementation dependent.

Table 11-20—ANQP usage

ANQP-element name	ANQP-element (subclause)	ANQP-element type	BSS		IBSS

Symbols
Q element is an ANQP request
S element is an ANQP response
T ANQP-element may be transmitted by MAC entity
R ANQP-element may be received by MAC entity
G Group addressed ANQP request/response may be transmitted and received by a MAC entity
— ANQP-element is neither transmitted nor received by MAC entity

A STA receiving a CAG ANQP-element in an ANQP response should cache the ANQP-element contents, for later use. The STA caches the ANQP CAG Version and ANQP responses corresponding to each Info ID from the received CAG ANQP-element together with the values of BSSID, or HESSID and the corresponding SSID of the responding AP's BSS. The STA obtains the required ANQP responses either as an ANQP response to a previous ANQP request, or by transmitting an ANQP request for the ANQP response .

The AP obtains the current value of a CAG Version from the associated advertisement server. How the AP obtains the value of the CAG Version from the associated advertisement server is out of the scope of this standard.

When dot11InterworkingServiceActivated is true, an AP may provide one or more current version numbers of the CAG (CAG Version) associated with the AP, where each version number is associated with a specific advertisement protocol by including the CAG Number element in the Beacon or Probe Response frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

In order to reduce the network discovery delay at an AP, the BSSID, HESSID, or the corresponding SSID of that AP's BSS are used as a key index in the STA's cache to determine if an ANQP CAG Version received from an AP matches previously cached information.

A STA that makes use of the CAG Version is subject to the following:

— The STA may obtain the CAG Version from the CAG Number element received in Beacon or Probe Response frames.
— The STA searches its cached information using the BSSID, HESSID, or SSID of the AP's BSS as an index to obtain the correct cached ANQP CAG Version entry.
— If the cached ANQP CAG Version does not match the CAG version received in Beacon or Probe Response frames, the STA should transmit an ANQP request for any of the ANQP-elements contained within the CAG. If the CAG Versions do match, the STA should use the cached ANQP-elements corresponding to the CAG Version for network discovery.

The mapping of the ANQP CAG Version to the ANQP-elements by an advertisement server is outside the scope of this standard.

ANQP usage for infrastructure BSSs and IBSSs shall be in accordance with Table 11-20. ANQP usage defines the entities permitted to transmit and receive particular ANQP-elements.

A STA having dot11InterworkingServiceActivated equal to true shall support using the Query List ANQP-element to request the Capability List ANQP-element; support for all other ANQP-elements is optional.

A STA that encounters an unknown or reserved ANQP Info ID value in a GAS frame (see Table 9-426) received without error shall ignore that ANQP Info ID and shall parse any remaining ANQP Info IDs.

A STA that encounters an unknown vendor-specific OI field or subfield in a GAS frame (see 9-471) received without error shall ignore that field or subfield respectively, and shall parse any remaining fields or subfields for additional information with recognizable field or subfield values.

11.22.3.3.2 Query list procedure

The Query List ANQP-element is used by a requesting STA to perform an ANQP request using the procedures defined in 11.22.3.3.1. The requesting STA may include Info IDs in the Query List ANQP-element that do not include "Q" in the ANQP-element type as shown in Table 11-20; the STA shall not include other Info IDs. The requesting STA should only request the ANQP-elements it needs for its operation.

A responding STA that encounters an unknown or reserved ANQP Info ID value in an Query List ANQP-element received without error shall ignore that ANQP Info ID and shall parse any remaining ANQP Info IDs.

11.22.3.3.3 Roaming Consortium procedure

The Roaming Consortium ANQP-element, which contains a set of OIs, can be retrieved from an AP by a non-AP STA using the query list procedure defined in 11.22.3.3.2. The list of OIs included in the Roaming Consortium ANQP-element shall be those OIs in the dot11RoamingConsortiumTable. An AP may include an OI in the dot11RoamingConsortiumTable, if in conjunction with an AS, it is capable of successfully authenticating a non-AP STA having valid security credentials for the SSPN identified by that OI; the AP shall not include an OI otherwise. Methods used by the AP to authenticate the non-AP STA include, but are not limited to, RSNA algorithms and Open System authentication.

Each OI identifies an SSP or group of SSPs (i.e., a roaming consortium). An SSP or group of SSPs can register for and obtain an OI using the procedures described in IEEE SA FAQs—IEEE Registration Authority [B15].

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A non-AP STA might have a locally stored binding between an OI and a set of security credentials with which it can authenticate to the network identified by the OI, that is, the SSPN. The method by which this binding is obtained is outside the scope of this standard. A non-AP STA can select from that list of credentials when authenticating to the BSS.

11.22.3.3.4 AP procedure for advertising EAP Method associated with an NAI realm

When dot11RSNAActivated is true, NAI realms along with their supported authentication methods may be advertised using the NAI Realm ANQP-element (see 9.4.5.10). Each realm may optionally be associated with a set of EAP methods. Each EAP method may optionally be associated with a set of Authentication Parameters. The NAI realm ANQP-element provides a hint on the methods a STA might use to establish an association in an RSN IEEE 802.1X environment. If the non-AP STA recognizes the NAI realm, it may attempt authentication even if it believes the EAP methods are incorrect.

When dot11RSNAActivated is false and the Network Authentication Type (see 9.4.5.6) contains a Network Authentication Type Unit having a Network Authentication Type Indicator field equal to http/https redirection or DNS redirection, NAI realms without supported authentication methods may be advertised using the NAI Realm ANQP-element (see 9.4.5.10).

A non-AP STA having dot11InterworkingServiceActivated equal to true may process the NAI Realm ANQP-element. The selection of the NAI realm the non-AP STA uses for authentication is outside the scope of this standard. A non-AP STA requests the NAI Realm ANQP-element using Query List procedures defined in 11.22.3.3.2.

A non-AP STA having dot11InterworkingServiceActivated equal to true may process the EAP Method list as follows:

— The EAP Method list provided by the AP shall be in priority order (the most preferred EAP Method is listed first).
— The credential types help the STA to determine what credentials to use for authentication.
— The STA should confirm the GAS advertisement after an RSNA is established by performing a GAS query request for the NAI Realm ANQP-element using Protected Dual of Public Action frames.

NOTE—The advertisements should be confirmed after the RSNA is established to avoid downgrade attacks.

The policy that determines whether a non-AP STA should attempt authentication and/or association with any particular IEEE 802.11 Access Network is outside the scope of this standard.

11.22.3.3.5 3GPP Cellular Network procedure

A STA may retrieve 3GPP Cellular Network information using the Query List procedure in 11.22.3.3.2. Realms referenced in the 3GPP Cellular Network ANQP-element should not be included in the NAI Realm ANQP-element (see 9.4.5.10).

11.22.3.3.6 AP Geospatial Location procedure

A STA may retrieve an AP's geospatial location using the Query List procedure in 11.22.3.3.2. A STA in the associated state should retrieve geospatial location information from the AP using the procedures in 11.10.9.6.

11.22.3.3.7 AP Civic Location procedure

A STA may retrieve an AP's civic location using the Query List procedure in 11.22.3.3.2. A STA in the associated state should retrieve civic location information from the AP using the procedures in 11.10.9.9.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.22.3.3.8 AP Location Public Identifier URI/FQDN procedures

A STA when dot11InterworkingServiceActivated is true may retrieve an AP's Location Public Identifier URI or a location server's FQDN using ANQP procedures in 11.22.3.3. A STA in the associated state should retrieve Location Public Identifier URI/FQDN information from the AP using the procedures in 11.10.9.10.

NOTE—Due to security concerns, there are some URI schemes that ought to be cautiously processed when received by a STA. For example, URIs using the scheme names "data:" and "http:" might direct applications (e.g., a browser) on the STA to Internet pages that contain active scripts. Therefore, URIs received via this ANQP procedure ought not be processed in a general manner, as these scripts might be inadvertently activated.

11.22.3.3.9 Emergency NAI procedure

A STA that does not have valid credentials to authenticate to a network may use the information in the Emergency NAI ANQP-element as its EAP identity.

The Emergency NAI ANQP-element can be retrieved from the AP using the Query List procedure in 11.22.3.3.2.

The STA uses the emergency NAI procedure to indicate its intention to access the network without peer authentication by using the emergency NAI information as its identity in the authentication process, as described in IETF RFC 5216.

11.22.3.3.10 TDLS Capability procedure

A STA may use the TDLS Capability ANQP-element (see 9.4.5.18) to discover TDLS capabilities of another TDLS STA using the Query List procedure in 11.22.3.3.2.

An example of TDLS capability discovery using ANQP is given in Figure 11-84 .

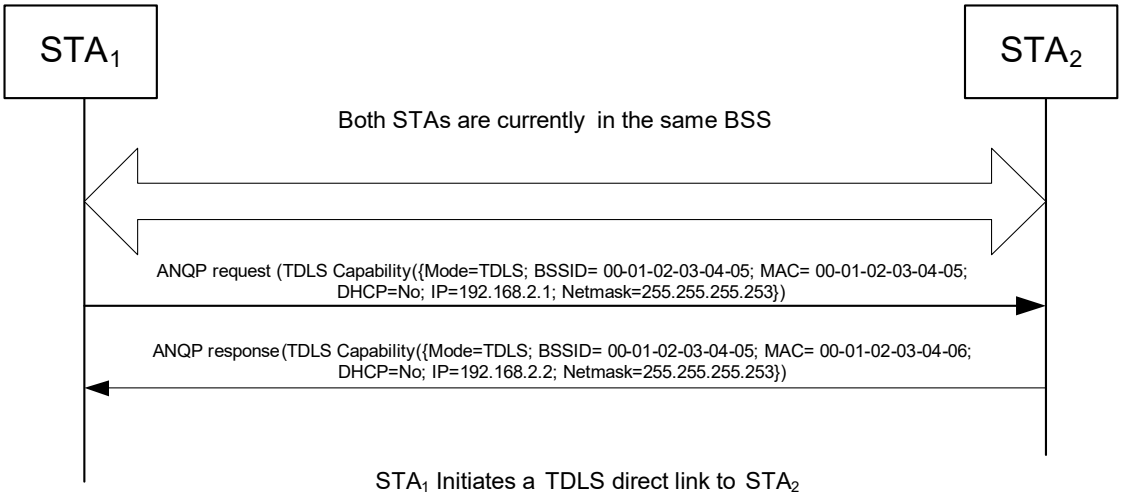

Figure 11-84—Example TDLS Capability discovery using ANQP

The mechanism shall work as follows:

a) STA1 determines the MAC address of STA2.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

b) STA1 sends an ANQP request to STA2. The ANQP request includes a TDLS Capability ANQP-element.
c) STA2 receives the ANQP request and updates the TDLS Capability ANQP-element based on its own capabilities that is returned in the ANQP response to STA1.

11.22.3.3.11 Venue URL procedure

The Venue URL ANQP-element is used to provide web page advertising services or information particular to the venue.

This ANQP-element is to be used in conjunction with the Venue Name ANQP-element, to provide extra information about the venue. Typical operation is to use the Venue Name ANQP-element to determine the list of available venues advertised by a STA, and then the Venue URL ANQP-element is used, if required, to determine a list of Venue URLs, each entry corresponding to the Venue Name entry in the list returned by the Venue Name ANQP-element.

11.22.3.3.12 Advice of Charge procedure

The Advice of Charge ANQP-element is used to provide financial cost advertisements in the form of advice of charge plan information. The plan information is provided on a per NAI realm basis, so that each authentication realm can advertise the charge associated with obtaining network access. This information might assist with a decision about proceeding with access. Plan information for the special NAI realm "*" is indicated, if none of the explicit NAI realms are currently applicable.

The use and operation of the Plan information schema is outside the scope of this standard.

As ANQP-elements are transmitted in the clear, prior to STA association, one or more Protected Dual of Public Action frames should be used after association to verify this information.

11.22.3.3.13 Local Content procedure

The Local Content ANQP-element is used to provide local content URLs. Each URL points to local content information that might be relevant, for example by providing information about terms and conditions for BSS access, when automated login procedures are being used.

Several URLs can be provided in the Local Content ANQP-element, each corresponding to a separate state. This allows the STA to display differing local content (e.g., terms and conditions, failure warning information, help page), through the STA association procedure.

For example, the Local Content ANQP-element may return two Local Content Duple fields with values of the State field corresponding to "Not authenticated" and "Failure during authentication." The requesting STA may display the contents of the local web page indicated by the first URL ("Not authenticated") showing terms and conditions of BSS access. If a subsequent association fails, then the requesting STA may display the contents of the local web-page indicated by the second URL ("Failure during authentication") showing a help page.

11.22.3.3.14 Query AP List procedure

The Query AP List ANQP-element is used by a requesting STA to perform a single ANQP request to an AP, using the procedures defined in 11.22.3.3.1 requesting the ANQP information on each AP indicated in the AP list. The requesting STA shall only include Info IDs in the Query List ANQP-element that do not include "Q" in the ANQP-element type as shown in Table 11-20. Info IDs that have an ANQP-element type of Q shall not be included in the Query AP List ANQP-element (e.g., the Info ID for Vendor Specific ANQP-element shall not be included).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A responding STA that encounters an unknown or reserved ANQP Info ID value in a Query AP List ANQP-element shall ignore that ANQP Info ID and shall parse any remaining ANQP Info IDs.

In the response to a Query AP List, the Query Response field contains an AP List Response ANQP-element. The AP List Response contains multiple query response reports for the APs indicated in the Query AP List. If the responding AP does not provide the requested information for all APs specified in the Query AP List, or for all the requested Info IDs, the STA interprets it as that information not available. How the information obtained from the AP list is used by the STA is left to the implementation and is beyond the scope of this standard.

11.22.3.3.15 CAG procedure

The CAG ANQP-element is used by a requesting STA to perform an ANQP request to retrieve the Info IDs contained within the CAG associated with ANQP, or ANQP with Service Information Registry, and the current ANQP CAG Version associated with these Info IDs. If the requesting STA to perform an ANQP request to retrieve the Info IDs related both to ANQP and to ANQP with Service Information Registry, the requesting STA shall use separate CAG ANQP-elements. For this purpose, a requesting STA shall use the procedures defined in 11.22.3.3.1 and 11.22.3.3.2 and shall include in the ANQP request the Info ID of the CAG ANQP-element as shown in Table 11-20. When a responding AP receives a Query List ANQP-element that contains the Info ID of CAG ANQP-element, the responding STA shall include in the GAS query response a CAG ANQP-element containing the ANQP CAG Version and the Info IDs of the ANQP-elements that are in the CAG associated with ANQP, or ANQP with Service Information Registry, in the increasing order of the Info ID values. If the responding STA receives Info IDs related both to ANQP and to ANQP with Service Information Registry, the responding STA shall include separate CAG ANQP-elements in the ANQP response. The ANQP response also includes the (other) ANQP-elements that a STA requested in the Query List ANQP-element in the increasing order of the Info ID values.

The ANQP CAG Version is an unsigned number and it is incremented when there is any change in the CAG associated with ANQP, or ANQP with Service Information Registry, including a change of the Info ID of the ANQP-elements of the CAG or a change in the values of the ANQP-elements included in the CAG. If the ANQP CAG Version exceeds 255, it is reset to 0.

11.22.3.3.16 Local MAC address policy procedure

The Local MAC Address Policy ANQP-element is used by a non-AP STA to discover the MAC address policy for an ESS. The STA should use a MAC address consistent with the local MAC address policy, as determined from the Local MAC Address Policy ANQP-element and the Local MAC Address Policy field in the Extended Capabilities field. An AP may send a DENIED_LOCAL_MAC_ADDRESS_POLICY_VIOLATION status code in an Association Response frame to a STA with a MAC address that is inconsistent with the MAC address policy.

11.22.3.3.17 Enhanced broadcast services procedures

EBCS traffic streams may be advertised using the EBCS ANQP-element (see 9.4.5.30) transmitted over a GAS query response in a GAS Initial Response frame or Group Addressed GAS Response frame. The element describes a set of zero or more EBCS traffic streams that are available from an AP. Each broadcast service advertisement may contain the time and duration of transmission, together with an identifier of the broadcast content (a content ID) and other information relevant to the broadcast service. The information present in each broadcast service advertisement is indicated in a Control field.

NOTE—An EBCS traffic stream signaled in an EBCS ANQP-element might be provided by a malicious user, since the ANQP-element might be unsecured. The origin authentication methods described in 12.15 might be used to authenticate the origin of EBCS traffic streams.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the content is authenticated in the MAC sublayer (nonzero values of the Content Authentication Algorithm field as defined in Table 9-436) or requires negotiation (i.e., one or more of the EBCS Content Request frames, EBCS Content ANQP element, or Out Of Band Request subfields of the Negotiation Method subfield, as defined in 9.4.5.30, are set to 1), the information provided by the EBCS ANQP-element needs to be augmented with additional information to receive the traffic stream. The information on the authentication and negotiation method may be obtained in the next EBCS Info frame as indicated by the Content Authentication Algorithm field and in the Negotiation Method field included in the EBCS ANQP-element.

If the content follows the authentication scheme defined in 12.15.4 as indicated by the Content Authentication Algorithm subfield equal to 0 as defined in Table 9-436, the information provided is enough to receive the traffic stream.

The EBCS ANQP-element may be transmitted using a Group Addressed GAS Response frame. In this case, all non-AP STAs and APs may receive the information on the services available at the transmitting AP.

If the EBCS Content Request ANQP-element is one of the permitted negotiation methods, a STA may use it to request registration (or unregistration) from a peer STA. This ANQP-element optionally allows the STA to provide the MAC address of the AP currently serving the EBCS traffic stream, which might not be the same as the one receiving the ANQP request.

11.22.3.3.18 Credentials and Privacy procedure

Some networks advertise support for multiple SSPs, for example through a roaming consortium However, the venue might only accept credentials from a subset of the roaming consortium members. In other scenarios, the venue may have specific constraints on the type of credentials that are acceptable, for example based on the identity verification conducted at the credential creation, or the age of the credentials. The Credential Types ANQP-element is used by a non-AP STA to discover the venue requirements for accepted credentials, which includes the SSP categories that are accepted, and the type of validation and age required for the credentials.

Authentication then occurs between the non-AP STA and the SSP through a protected tunnel. In some cases, the local venue requires the non-AP STA to also share locally a contactable identity. The Privacy Indicator field in the Credential Types ANQP-element provides an indication on the venue requirements for contactable identity allowing the STA to preserve the user's privacy when identity exposure is not needed.

A Credential Types Tuple subfield shall be ignored if the value in the Validation, Category Group and/or Category Type subfield is reserved.

A First or Second Settlement Indicator subfield and the corresponding First or Second SLA Indicator subfield, respectively, shall be ignored if the value in the First or Second Settlement Indicator subfield, respectively, is reserved.

In some venues, a subset of SSP credentials might not be accepted, for example because they are local competitors. The Excluded NAI Realm ANQP-element provides a list of realms from which credentials are not accepted by the AP.

When multiple credentials are accepted, the local venue may have specific agreements with each SSP based on the roaming profile. The SLA ANQP-element provides the STA with information about the SLA locally available based on the roaming type.

NOTE—How the non-AP STA uses the information indicated by the venue is out of scope of the standard. It is assumed the non-AP STA has a set of local information about credentials that are available, or policies that are acceptable, and proceeds with a connection based on matching this information to the indicated information.

11.22.3.4 Registered location query protocol (RLQP) procedures

When dot11GDDActivated is true, a STA may use RLQP to retrieve information as defined in Table 9-277 from a peer STA that has transmitted an Advertisement Protocol element indicating support for RLQP (see 9.4.2.91) in a Beacon or Probe Response frame.

If information is not configured for a particular RLQP-element, then a query for that element returns that element with no optional fields.

When RLQP is transmitted between a GDD enabling STA and the RLSS, MSDUs with EtherType 89-0d shall be used, as defined in Annex H. The Payload field of the MSDUs contains RLQP-elements as specified in 9.4.6. When an RLQP-element is transmitted between a GDD dependent STA and its GDD enabling STA, protected Action frames shall be used, not MSDUs with EtherType 89-0d.

NOTE 1—In some regulatory domains, the GDD enabling STA may be required to have a secured connection with the RLSS.

When security is required by regulation, the Payload field of the MSDUs with EtherType 89-0d body may employ corresponding security features. Alternatively, various security protocols may also be selected by setting the EtherType field to respective values. The IEEE Registration Authority provides a public listing of EtherTypes and other identifiers at https://regauth.standards.ieee.org/standards-ra-web/pub/view.html#registries.

11.22.4 Interworking procedures: IEEE 802.21 MIS support

IEEE Std 802.21-2017 enables the optimization of services when performed between heterogeneous IEEE 802 networks. IEEE Std 802.21.1-2017 defines a handover service, which is used in conjunction with IEEE Std 802.21-2017.

STAs with dot11InterworkingServiceActivated equal to true and dot11GASAdvertisementId equal to MIS Information Service (see Table 9-277) shall support the transmission and reception of IEEE 802.21 MIIS queries for STAs in all states. STAs with dot11InterworkingServiceActivated equal to true and dot11GASAdvertisementId equal to MIS Command and Event Services Capability Discovery (see Table 9-277) shall provide support for IEEE 802.21 MICS/MIES capability discovery for non-AP STAs in all states.

Additionally, support for IEEE 802.21 MIIS query and IEEE 802.21 MICS/MIES capability discovery to non-AP STA’s in the associated state is provided by the STA forwarding IP datagrams destined for the MIS point of service to the IEEE 802.21 MIIS server.

A non-AP STA discovers support for these services by receiving Beacon or Probe Response frames with an Advertisement Protocol element having advertisement protocol ID(s) for MIS Information Service and/or IEEE 802.21 MICS/MIES capability discovery.

A non-AP STA forms an IEEE 802.21 information service query by creating its query request according to the procedures defined in IEEE Std 802.21-2017 and formatting that request into an IEEE 802.21 MIS protocol frame as defined in 8.4 of IEEE Std 802.21-2017. The non-AP STA, using the procedures in 11.22.3.2, posts the query to an IEEE 802.21 Information Server by transmitting the MIS formatted frame in the Query Request field of a GAS Initial Request frame. The Advertisement Protocol ID field in the GAS Initial Request frame is set to the value of IEEE 802.21 MIS Information Service (Table 9-277).

Non-AP STAs in the unauthenticated or unassociated or associated states can use GAS procedures to discover MIS Command and Event Services Capability as specified in Table 9-277.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A non-AP STA forms an IEEE 802.21 MIS Command and Event Service discovery request by encapsulating an MIS_Capability_Discover request into an MIS protocol frame as defined in 8.4 of IEEE Std 802.21-2017. The non-AP STA, using the procedures in 11.22.3.2, posts the discovery request to the network by transmitting the MIS formatted frame in the Query Request field of a GAS Initial Request frame. The Advertisement Protocol ID field in the GAS Initial Request frame is set to the value of MIS Command and Event Services Capability Discovery (Table 9-277). The method by which the AP relays the discovery request to the network is defined in IEEE Std 802.21-2017 and is outside the scope of this standard.

A non-AP STA retrieves the IEEE 802.21 MIS Command and Event Service discovery response according to the procedures in 11.22.3.2. The discovery response is an MIS protocol frame as defined in 8.4 of IEEE Std 802.21-2017.

11.22.5 Interworking procedures: interactions with SSPN

11.22.5.1 General operation

To provide SSPN Interface services, the IEEE 802.11 network interacts with the SSPN corresponding to the user of the non-AP STA either directly or via a roaming relationship. As part of setting up the RSN security association, user policies are communicated to the AP. If dot11SSPNInterfaceActivated is true, these permissions shall be stored in the AP's dot11InterworkingTableEntry for that STA. Thereafter, the AP shall use the dot11InterworkingTableEntry for controlling the service provision to that non-AP STA. User policies from the SSPN affect authentication, authorization, and admission control decisions at the AP. In addition, the AP collects statistics about the non-AP STA and reports the statistics to the SSPN when requested. The SSPN may also send service provision instructions to the AP, e.g., to terminate the connection to a non-AP STA. Non-AP STAs do not support the SSPN Interface.

Network deployments typically provide that the AP and the server in the SSPN have a trustworthy channel that can be used to exchange information, without exposure to or influence by any intermediate parties. The establishment of this secure connection between the IEEE 802.11 infrastructure and the SSPN is outside the scope of this standard.

11.22.5.2 Authentication and cipher suites selection with SSPN

When the non-AP STA initiates IEEE 802.1X authentication, the EAP messages are forwarded to the SSPN based on the NAI realm provided by the non-AP STA. If the IEEE 802.11 infrastructure is unable to forward the EAP message, the AP when dot11SSPNInterfaceActivated is true shall disassociate the non-AP STA with Reason Code NO_SSP_ROAMING_AGREEMENT.

In addition to the EAP messages, the IEEE 802.11 infrastructure also provides extra information regarding the non-AP STA to the SSPN as defined in R.4.2, e.g., the Cipher Suite supported by non-AP STA, the location of the AP to which the non-AP STA is associated, etc. Such information may be used by the SSPN to make authentication and service provisioning decisions.

In the SSPN Interface Service, the SSPN uses more information than is carried over EAP to decide on the authentication result. The SSPN might reject a connection request if the cipher suites supported by non-AP STA does not meet its security requirements. In this situation, the SME of the AP when dot11SSPNInterfaceActivated is true shall invoke a disassociation procedure as defined in 11.3.5.8 by issuing the MLME-DISASSOCIATE.request primitive. The AP disassociates the corresponding non-AP STA with Reason Code BAD_CIPHER_OR_AKM.

The SSPN might reject the association request based on the location of the non-AP STA, e.g., if the non-AP STA is requesting association to an AP or associated to an AP located in a forbidden zone. In this situation, the SME of the AP when dot11SSPNInterfaceActivated is true shall invoke a disassociation procedure as defined

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

in 11.3.5.8 by issuing the MLME-DISASSOCIATE.request primitive. The AP disassociates the corresponding non-AP STA with Reason Code NOT_AUTHORIZED_THIS_LOCATION.

11.22.5.3 Reporting and session control with SSPN

An AP with dot11SSPNInterfaceActivated equal to true shall create a dot11InterworkingEntry in its dot11InterworkingTable for each STA that successfully associates. Permissions received from the SSPN for each associated STA shall be populated into the table; if no permissions are received from the SSPN for a particular non-AP STA, then the default permissions or an AP's locally defined policy may be used for that STA's dot11InterworkingEntry. If the AP's local policy is more restrictive than an object's permission value received from the SSPN Interface, then the AP's local policy may be enforced instead.

In an AP when dot11SSPNInterfaceActivated is equal to true, the following procedure occurs:

— The non-AP STA's state contained in the dot11InterworkingEntry shall be transmitted to the new AP after a successful transition. The state definition and the protocol used to transfer the state are beyond the scope of this standard. The new AP shall not forward any frames for that non-AP STA until it receives the dot11InterworkingEntry from the prior AP.

— After the state is successfully transmitted to the new AP, the dot11InterworkingEntry for that non-AP STA shall be deleted from the prior AP's dot11InterworkingTable.

An AP with dot11SSPNInterfaceActivated equal to true shall delete the dot11InterworkingEntry for a non-AP STA when it disassociates from the BSS.

An AP with dot11SSPNInterfaceActivated equal to true shall enforce the dot11InterworkingEntry limits for a particular non-AP STA by comparing the values of octet counters to authorized access limits:

— dot11NonAPStationVoiceOctetCount is compared to dot11NonAPStationAuthMaxVoiceOctets. When the value of the authorized maximum octet count is exceeded, if the ACM subfield for AC_VO is equal to 1, then the HC shall delete all admitted TSs on this access category and deny all subsequent ADDTS Request frames with TID set to 6 or 7; or if the ACM subfield for AC_VO is equal to 0, then the non-AP STA shall be disassociated using the MLME-DISASSOCIATE.request primitive with a reason code of PEER_INITIATED.

— dot11NonAPStationVideoOctetCount is compared to dot11NonAPStationAuthMaxVideoOctets. When the value of the authorized maximum octet count is exceeded, if the ACM subfield for AC_VI is equal to 1, then the HC shall delete all admitted TSs on this access category and deny all subsequent ADDTS Request frames with TID set to 4 or 5; or if the ACM subfield for AC_VI is equal to 0, then the non-AP STA shall be disassociated using the MLME-DISASSOCIATE.request primitive with a reason code of PEER_INITIATED.

— dot11NonAPStationBestEffortOctetCount is compared to dot11NonAPStationAuthMaxBestEffortOctets. When the value of the authorized maximum octet count is exceeded, if the ACM subfield for AC_BE is equal to 1, then the HC shall delete all admitted TSs on this access category and deny all subsequent ADDTS Request frames with TID set to 0 or 3; or if the ACM subfield for AC_BE is equal to 0, then the non-AP STA shall be disassociated using the MLME-DISASSOCIATE.request primitive with a reason code of PEER_INITIATED.

— dot11NonAPStationBackgroundOctetCount is compared to dot11NonAPStationAuthMaxBackgroundOctets. When the value of the authorized maximum octet count is exceeded, if the ACM subfield for AC_BK is equal to 1, then the HC shall delete all admitted TSs on this access category and deny all subsequent ADDTS Request frames with TID set to 1 or 2; or if the ACM subfield for AC_BK is equal to 0, then the non-AP STA shall be disassociated using the MLME-DISASSOCIATE.request primitive with a reason code of PEER_INITIATED.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— dot11NonAPStationHCCAHEMMOctetCount is compared to dot11NonAPStationAuthMaxHCCAHEMMOctets. When the value of the authorized maximum octet count is exceeded, then the HC shall delete all admitted TSs with access policy of HCCA or HEMM and deny all subsequent ADDTS Request frames with access policy equal to HCCA or HEMM.

— The sum of dot11NonAPStationVoiceOctetCount, dot11NonAPStationVideoOctetCount, dot11NonAPStationBestEffortOctetCount, dot11NonAPStationAuthMaxBackgroundOctets, and dot11NonAPStationHCCAHEMMOctetCount is compared to dot11NonAPStationAuthMaxTotalOctets. When the value of the authorized maximum octet count is exceeded, the non-AP STA shall be disassociated using the MLME-DISASSOCIATE.request primitive with a reason code of PEER_INITIATED.

11.22.6 Interworking procedures: emergency services support

Emergency services support provides STAs with the ability to contact authorities in an emergency situation. The following procedures allow the STA to determine whether emergency services are supported by the AP or mesh STA, and whether unauthenticated emergency service access is allowed.

In an AP, when dot11ESNetwork is true, the network is dedicated and limited to accessing emergency services. When dot11ESNetwork is true, the Access Network Type field in the Interworking element shall be set to the value for “Emergency services only network” (see Table 9-276). When dot11ESNetwork is false, the network is not limited to accessing emergency services, and the Access Network Type field in the Interworking element shall be set to a value other than “Emergency services only network.” See Table 11-21.

Table 11-21—ESR and UESA field settings

Description	ESR	UESA
It is unspecified whether emergency services are reachable.	0	0
Emergency services are only reachable for authenticated STAs.	1	0
Reserved	0	1
Emergency services are reachable for STAs.	1	1

When an AP is located in a regulatory domain that requires emergency location capabilities, the ESR field shall be set to 1; otherwise the ESR field shall be set to 0. When an AP is located in a regulatory domain that requires emergency location capabilities and location capability is enabled on the AP, the Network Type shall be set to “Emergency services only network” (see Table 9-276), if location capability is enabled on the AP; otherwise the ESR field shall not be set to 1 and the Network Type shall not be set to “Emergency services only network”. In Beacon and Probe Response frames, location capability is advertised when the Civic Location or Geo Location field in the Extended Capabilities element is set to 1.

In an MBSS, if location capability is supported, the mesh STA shall report its location for emergency services.

When dot11ESNetwork is true in a mesh STA, the ESR shall be set to 1. When that mesh STA receives a Mesh Peering Open frame that includes the Interworking element with the ASRA field equal to 1, it allows access to emergency services and forwards MSDUs to an emergency server.

NOTE—The ASRA bit set to 1, informs the mesh STA to prioritize resources for the emergency call, to proactively find a better path before the link conditions deteriorate below a certain threshold, and/or to change some of the mesh STA’s behavior (for example, to disable any power save features).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When dot11ESNetwork is false in a mesh STA, the ESR shall be set to 0. When that mesh STA receives a Mesh Peering Open frame that includes the Interworking element with the ASRA field equal to 1, it is unable to support the mesh peering of emergency services and does not forward MDSUs to an emergency server.

11.22.7 Interworking procedures: emergency alert system (EAS) support

The EAS provides alerts, typically issued by authorities. The Interworking Procedures EAS support enables the alerts to be transmitted upon request from APs to non-AP STAs. Subsequent to advertisement in Beacon and Probe Response frames, a non-AP STA uses GAS queries to retrieve an EAS message from the network according to the following procedures.

When dot11EASActivated is true, EAS operation shall be supported. When EAS operation is not supported, dot11EASActivated shall be false.

When the IEEE 802.11 infrastructure is informed of the availability of an EAS message (the mechanism by which is outside the scope of this standard), an AP with dot11EASActivated equal true shall advertise the availability of the EAS message by including an Emergency Alert Identifier element (see 9.4.2.95) for that message in its Beacon and Probe Response frames. The AP shall include one instance of an Emergency Alert Identifier element in its Beacon and Probe Response frames for each active EAS Message. The Emergency Alert Identifier element provides an Alert Identifier Hash field value, a unique indicator of the EAS Message of the alert to the non-AP STA. The Alert Identifier Hash field value allows the non-AP STA to determine whether this is a new alert.

NOTE—The same value of hash is computed by each AP in an ESS and by each AP in different ESSs. Thus a non-AP STA, which can download emergency alert messages when in a preassociated state, can unambiguously determine that it has already downloaded the message, avoiding unnecessary duplicates.

When an EAS Message has expired (the mechanism by which is outside the scope of this standard), an AP with dot11EASActivated equal true shall remove the corresponding instance of an Emergency Alert Identifier element from its Beacon and Probe Response frames.

The Alert Identifier Hash field in the Emergency Alert Identifier element shall be computed using HMAC-SHA-1-64 hash algorithm as shown in 9.4.2.95.

After receiving an Alert Identifier Hash field value for an EAS Message that has not already been retrieved from the network, a non-AP STA having dot11EASActivated equal true can retrieve the EAS message from the AP as follows:

— The procedures defined in 11.22.3.2, transmit the Alert Identifier Hash field of the desired message in the Query request field of a GAS Initial Request frame. The Advertisement Protocol ID field in the GAS Initial Request frame is set to the value for EAS (see Table 9-277).
— The Query response is a message formatted in accordance with OASIS EDXL (see OASIS Standard EDXL-DE).
— A URI is formed by concatenating the Emergency Alert URI with the hexadecimal numerals of the Alert Identifier Hash field converted to lowercase ASCII encoded characters and the ".xml" file extension. For example, if the Emergency Alert URI is http://eas.server.org and the Alert Identifier Hash is 0x1234567890abcdef, then the URI would be http://eas.server.org/1234567890abcdef.xml (the mechanism by which the URI is retrieved is outside the scope of this standard). The XML file is formatted in accordance with OASIS EDXL. The non-AP STA retrieves the Emergency Alert URI (see 9.4.5.16) using an ANQP request according to the procedures in 11.22.3.3. This method is recommended for non-AP STAs in the associated state.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.22.8 Interworking procedures: support for the advertisement of roaming consortiums

APs can assist non-AP STAs performing network discovery and selection through the advertisement of a Roaming Consortium element. The Roaming Consortium element contains information identifying an SSP or group of SSPs (i.e., a roaming consortium) whose security credentials might be used to authenticate with the AP transmitting this element. An SSP or group of SSPs can register for and obtain an OI using the procedures described in IEEE SA FAQs—IEEE Registration Authority [B15]. Note that a non-AP STA may also use GAS procedures defined in 11.22.3.3.3 to retrieve a Roaming Consortium ANQP-element, which might contain more OIs than the Roaming Consortium element.

APs having dot11InterworkingServiceActivated equal true and having one or more entries in the dot11RoamingConsortiumTable shall include the Roaming Consortium element in Beacon and Probe Response frames. An AP shall only include an OI in the dot11RoamingConsortiumTable, if, in conjunction with an AS, the AP is capable of successfully authenticating a non-AP STA that holds valid security credentials for the SSPN identified by that OI. Methods used by the AP to authenticate the non-AP STA include, but are not limited to, RSNA algorithms and Open System authentication.

A non-AP STA might have a locally stored binding between an OI and a set of security credentials with which it can authenticate to the network identified by the OI, that is, the SSPN. The method by which this binding is obtained is outside the scope of this standard. A non-AP STA might select from that list of credentials when authenticating to the BSS.

11.22.9 Interworking procedures: support for QoS mapping from external networks

Maintaining proper end-to-end QoS is an important factor when providing interworking service. This is because the external networks might employ different network-layer (Layer 3) QoS practices. For example, the use of a particular differentiated services code point (DSCP) for a given service might be different between different networks. To provide proper QoS over-the-air in the IEEE 802.11 infrastructure, the mapping from DSCP to UP for the corresponding network needs to be identified and made known to the STAs. If an inconsistent mapping is used then:

— Admission control at the AP may incorrectly reject a service request, because the non-AP STA used the incorrect UP.
— Non-AP STAs might use the incorrect value for User Priority in TSPEC and TCLAS elements.
— The user might be given a different QoS over the IEEE 802.11 network than expected, e.g., a lower QoS might be provided than the STA expected.

Therefore, APs with dot11QosMapActivated equal true shall set the QoS Map field in the Extended Capabilities element to 1; APs with dot11QosMapActivated equal false shall set the QoS Map field in the Extended Capabilities element to 0. The AP's SME causes the QoS mapping to be available to higher layer protocols or applications so they are able to set the correct priority in an MA-UNITDATA.request primitive.

For frames transmitted by an AP belonging to an admitted TS, the UP obtained from the TS's TCLAS element shall be used instead of the UP derived from the QoS mapping. For frames transmitted by an AP belonging to an admitted TS not having a TCLAS element, the UP shall be derived from the QoS mapping.

Non-AP STAs, when dot11QosMapActivated is equal true, shall set the QoS Map field in the Extended Capabilities element to 1. An AP receiving an Association Request frame or Reassociation Request frame when the QoS Map field in the Extended Capabilities element is equal 1 shall include the QoS Map element in the corresponding Association Response frame or Reassociation Response frame as defined in 9.3.3.6 or 9.3.3.8, respectively. Upon receiving the QoS Map element, the non-AP STA's SME causes the QoS mapping to be available to higher layer protocols or applications so they are able to set the correct priority in an MA-UNITDATA.request primitive.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When the AP's SME detects a change in the QoS mapping information, it shall update the non-AP STA with the new QoS Map element. It accomplishes this update by invoking the MLME-QOS-MAP.request primitive.

When the MAC entity at the non-AP STA receives a QoS Map Configure frame from the AP, the MLME shall issue an MLME-QOS-MAP.indication primitive to its SME.

When the non-AP STA's SME receives the QoS Map response, it shall make the QoS Map available to higher layers so that in turn, they can invoke the MA-UNITDATA.request primitive with the correct priority.

11.23 Preassociation discovery (PAD) procedures

11.23.1 General

There are two types of PAD procedures: unsolicited and solicited. The unsolicited PAD procedure is described in 11.23.2, and the solicited PAD procedure is described in 11.23.3.

When dot11UnsolicitedPADActivated or dot11SolicitedPADActivated is true, a non-AP and non-PCP STA may use PAD procedures to allow the SIC to discover the availability of services that the same non-AP and non-PCP STA may access when associated. While the specification of service-specific information is outside the scope of this standard, the service-specific information in the BSS is proxied by a SIR (see 4.5.9.2.4), which might be colocated with the AP or PCP.

A non-AP STA with dot11SolicitedPADActivated set to true may set dot11MACPrivacyActivated to true (see 12.2.11).

An AP advertises support for PAD by setting the PAD field of the Extended Capabilities element to 1 in its Beacon and Probe Response frames.

A PCP advertises support for PAD by setting the PAD field of the Extended Capabilities element to 1 in its DMG Beacon, Announce, and Probe Response frames.

11.23.2 Unsolicited PAD procedure

When dot11UnsolicitedPADActivated is true, an AP shall advertise services from an SIR using a Service Hint element or a Service Hash element, or both, in Beacon and Probe Response frames. Each service may be advertised using either a Service Hint element or a Service Hash element, but not both, in a Beacon or Probe Response frames.The MLME-UPDATE.request primitive shall be used by the SME to indicate the Service Hint and Service Hash elements to the MLME.

When dot11UnsolicitedPADActivated is true, a PCP shall advertise services from an SIR using a Service Hint element or a Service Hash element, or both, in DMG Beacon, Announce, or Probe Response frames. Each service may be advertised using either a Service Hint element or a Service Hash element, but not both, in DMG Beacon, Announce, or Probe Response frames.

A Service Hint element is used to advertise the presence of one or more services reachable via a BSS with a probability of matching a wrong service as indicated in the False Positive Probability Range subfield of the Service Hint element. A Service Hash element is used to advertise the presence of one or more services reachable via a BSS with a negligible probability of matching a wrong service. The mechanism for selecting which of a Service Hash or Service Hint element to use to advertise a particular service is beyond the scope of this standard.

When dot11UnsolicitedPADActivated is true, a non-AP and non-PCP STA searching for a service shall perform the following steps for each BSS:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

a) From the received Beacon, DMG Beacon, Announce, or Probe Response frames, process the Service Hash elements to generate a list of services reachable via the BSS, and process the Service Hint elements to determine the parameters of the bloom filter.
b) Construct a list comprising service hash values for each service being searched. Then determine the bit positions in the Bloom Filter Array field to be set to 1 for each service in the list.
c) For each service being searched, determine whether there is a matched service within the list of services, based on either of the following:
    1) The service hash value in the list of services matches the corresponding service hash value constructed in step b).
    2) The values of the bit positions of the Bloom Filter Bit Array field of the Service Hint element, as determined in step b), are all equal to 1.

The non-AP and non-PCP STA may use the resulting information about which services are reachable as input to network discovery and selection procedures. The non-AP and non-PCP STA might proceed with the solicited PAD procedure (see 11.23.3) or authentication and association procedure (see 11.3) based on the indicated false positive probability and the requirements of the service or the SIC (see the examples in Annex Y).

11.23.3 Solicited PAD procedure

When dot11SolicitedPADActivated is true, a non-AP and non-PCP STA may transmit to an AP or PCP a Service Information Request ANQP-element to request information from the SIR about services reachable via the BSS. A non-AP and non-PCP STA may use the Interworking and PAD fields of the Extended Capabilities element received from the AP or PCP to determine whether that AP or PCP supports Solicited PAD.

NOTE—An Interworking field value of 1 implies support for ANQP.

The Service Information Request ANQP-element is used by a non-AP and non-PCP STA to request detailed information about services reachable via the BSS; see examples illustrated in Annex Y.

When dot11SolicitedPADActivated is true, a non-AP and non-PCP STA may send a Service Information Request ANQP-element (see 9.4.5.27) to obtain information about a matching service. The Service Information Request ANQP-element shall include one or more Service Information Request Tuple subfields. Each Service Information Request Tuple subfield shall include a service hash within the Service Hash subfield and a Service Information Request Attribute subfield that is a service-specific request.

When dot11SolicitedPADActivated is true, an SIR shall use the information from the Service Information Request ANQP-element to determine whether the requested service(s) are reachable via the BSS. If matching services are found, corresponding to the Service Hash subfield, the SIR shall respond by requesting the AP or PCP to transmit a Service Information Response ANQP-element that contains a Service Information Response Tuple subfield for each service that satisfies the request. The Service Information Response ANQP-element contains detailed information about the services. When there is no matching service corresponding to the Service Hash subfield in an individually addressed GAS Initial Request frame, the SIR shall respond by requesting the AP or PCP to transmit a Service Information Response ANQP-element containing zero Service Information Response Tuple subfields.

The SIC receives service information from the contents of the Service Information Response ANQP-element. The non-AP and non-PCP STA may use the service information regarding which services are reachable as input to network discovery and selection procedures. The non-AP and non-PCP STA might proceed with the authentication and association procedure (see 11.3) (see examples illustrated in Annex Y).

11.23.4 Service hash procedure

A service hash is generated from a service name after all single octet uppercase alphabetic characters in the service name are converted into corresponding lowercase characters. A service name is defined in IETF RFC 6335.

A service hash contained in the Service Hash subfield of the Service Hash element, or in the Service Information Request ANQP-element, or in the Service Information Response ANQP-element, or a service hash used to map into the Bloom Filter Bit Array is generated as follows:

service hash = ExtractBits(SHA-256(service name), 0, 48)

For example, a service hash for the service name of "_ipp._tcp" is created as follows: The service hash contained in the Service Hash subfield of the Service Hash element, the Service Information Request ANQP-element, and the Service Information Response ANQP-element is 0xbfd39037d25c, and the service hash used as input to compute the Bloom Filter Bit Array field is 0xbfd39037d25c.

11.23.5 Bloom filter hash function operation

The Bloom filter for a set of service hashes is created as described below.

Let m denote the number of bits in the Bloom filter, and let $k-1$ be the setting of the Number Of Hash Functions subfield in the Bloom Filter information field (see 9.4.2.236 (Service Hint element)), i.e., k is the number of Bloom filter hash functions (out of a maximum of 16) used by the Bloom filter. For example, when the Number Of Hash Functions subfield is equal to 1, $k = 2$, the first two hash functions are used (j =0x00,0x01).

Create the Bloom filter as follows:

a) Set all bits in the Bloom filter to 0.
b) For each service hash in the set of service hashes, compute the k bit positions by setting $j = 0, \ldots, k-1$, in the function H(j,X,m) shown below. Set the bits at the k computed bit positions to 1. Note that, in some cases, different values of j may return the same bit position.

Let H(j,X,m) denote the Bloom filter hash function,

where

j is the Bloom filter hash function prepend parameter used in the computation; j is a single octet and ranges from 0x00 to 0x0F
X is the service hash that is mapped into the Bloom Filter Bit Array field (see 11.23.4 for procedures for generating a service hash used to map into the Bloom Filter Bit Array field)
m is the size, in number of bits, of the Bloom filter; how the size of the Bloom filter is determined is out of the scope of this standard

H(j,X,m) is computed as follows:

Step 1: Compute A(j,X) = [j || X].
Step 2: Compute B(j,X) = CRC32(A(j,X)) & 0x0000FFFF. In other words, obtain the least significant 2 octets of the 32-bit CRC of A(j,X), where CRC32() is the same 32-bit CRC as defined in 9.2.4.9.
Step 3: H(j,X,m) = B(j,X) mod m.

11.24 Quality-of-service Management frame (QMF)

11.24.1 General

11.24.1.1 Overview

A QMF STA shall set dot11QMFActivated and dot11QosOptionImplemented to true. The QMF STA shall assign an access category to each Management frame according to the access category assignments indicated in the QMF policy that has been configured using the configuration procedures described in 11.24.2.

A QMF STA shall set the QMFActivated subfield in the Extended Capabilities element to 1.

A Management frame shall be transmitted as an IQMF when all five of the following conditions are met:

— The RA of the Management frame corresponds to an individual address.
— The frame is transmitted by a QMF STA.
— The transmitting STA has previously received an Extended Capabilities element from the STA corresponding to the RA of the frame being transmitted.
— The most recently received such Extended Capabilities element indicated that the STA is a QoS STA and has the value of 1 in the QMFActivated subfield.
— The frame is not a time priority Management frame.
— The frame is not a PV1 Management frame.

A QMF AP shall transmit a Management frame as a GQMF when all three of the following conditions are met:

— The RA of the Management frame corresponds to a group address.
— The transmitting STA has received an Extended Capabilities element that has the QMFActivated subfield equal to 1 from every member of the BSS corresponding to the BSSID field of the Management frame.
— The frame is not a time priority Management frame.
— The frame is not a PV1 Management frame.

A non-AP QMF STA shall transmit a Management frame as a GQMF when all three of the following conditions are met:

— The RA of the Management frame corresponds to a group address.
— The transmitting STA has received an Extended Capabilities element that has the QMFActivated subfield equal to 1 from its associated AP.
— The frame is not a time priority Management frame.
— The frame is not a PV1 Management frame.

A Management frame shall not be transmitted as an IQMF or GQMF, except as defined above.

NOTE—All APs in an ESS need to have the same QMF settings when GQMF has been enabled for use by associated non-AP STAs.

When the QMFActivated subfield is zero in the most recently received Extended Capabilities element from a destination STA, or when an Extended Capabilities element has not been received from a destination STA, a transmitting QMF STA shall transmit individually addressed Management frames to that destination STA using access category AC_VO.

If the QMFActivated subfield in the most recently received Extended Capabilities element from a destination QMF STA is equal to 1, but no QMF Policy element has been received from the destination QMF STA, and, if

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

associated, no QMF Policy element has been received from the QMF AP with which the STA is associated, then a QMF STA shall transmit all IQMFs to the destination QMF STA using the default QMF policy access categories defined in Table 11-22. Otherwise, the QMF STA shall transmit individually addressed Management frames as defined in the QMF policy included in the QMF Policy element accepted from the destination QMF STA. In either case, the transmitted Management frames are IQMFs, and the transmitting QMF STA shall indicate the access category used to transmit the frame in the ACI subfield of the sequence number field.

A QMF STA in an unassociated state shall transmit all group addressed Management frames as non-QMF. An associated QMF STA shall follow the QMF policy dictated by its associated AP for transmitting GQMFs as described in 11.24.2. The specific access category assignments of different Management frames in a nondefault QMF policy are beyond the scope of this document. The transmitting QMF STA shall indicate the access category used to transmit GQMFs in the ACI subfield of the sequence number field.

Time priority Management frames, when not sent as an immediate response, shall be transmitted using AC_VO.

A QMF STA shall not modify the access category of an IQMF or GQMF frame after an initial transmission of the frame has been performed, regardless of any subsequent modification to the QMF policy under which the STA is operating.

11.24.1.2 Default QMF policy

The default QMF policy is defined in Table 11-22. It defines the access category of each Management frame based on management subtype value, category value, and action value. QMFs not included in this table shall be assigned an access category AC_BE.

Table 11-22—Default QMF policy

Description	Management Frame Subtype value from Table 9-1	Category value from Table 9-81	Action field	QMF access category
(Re)Association Request/Response	0000–0011	N/A	N/A	AC_VO

11.24.2 QMF policy advertisement and configuration procedures

11.24.2.1 Overview

QMF policies are exchanged and implemented between two QMF STAs. A STA's QMF policy is advertised and exchanged using the QMF Policy element described in 9.4.2.118.

A non-AP QMF STA operating in a BSS shall not transmit a QMF Policy frame to an AP.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The access category for a QMF that is transmitted by a non-AP QMF STA to a peer QMF STA shall be determined from the QMF policy received from the peer if a QMF policy has been received from the peer. Otherwise, the default policy shall be used. The access category for a QMF that is transmitted by a QMF AP is determined from the QMF policy configured at that AP.

In a BSS or MBSS, the access category for any Management frame may be reconfigured.

11.24.2.2 QMF policy change in an infrastructure BSS or in an MBSS

A QMF Policy Change frame is transmitted by a QMF STA to request a change to the QMF policy that the requesting QMF STA uses for transmitting Management frames to the peer QMF STA in an infrastructure BSS or in an MBSS.

A STA may transmit a QMF Policy Change frame to request a change in the QMF policy for transmitting to a peer STA. A non-AP QMF STA that receives a QMF Policy Change frame may either accept or reject the request. An associated non-AP QMF STA may transmit a QMF Policy Change to the QMF AP in its BSS only if the Extended Capabilities element received from the AP has its QMFReconfigurationActivated subfield equal to 1. If the AP rejects the request, the associated QMF STA shall not request the same policy reconfiguration from the AP during the lifetime of its association.

An AP shall respond to a QMF Policy Change frame received from an associated STA by transmitting a QMF Policy frame. If the QMFReconfigurationActivated subfield is zero in the Extended Capabilities element in the Beacon frame, an AP that receives a QMF Policy Change frame from an associated STA shall respond with a QMF Policy frame, with the Status Code field set to REQUEST_DECLINED. If the QMFReconfigurationActivated subfield is 1 in the Extended Capabilities element in the Beacon frame, an AP that receives a QMF Policy Change frame from an associated STA shall evaluate the QMF Policy included in the frame, and shall respond to the request with the resulting QMF Policy element and the Status Code field set to SUCCESS if it accepts the policy change, or REQUEST_DECLINED if it rejects the policy change. A QMF AP may transmit a QMF Policy frame with the Status Code field set to SUCCESS to an associated QMF STA without having first received a QMF Policy Change frame from that STA.

If an accept status is received in a QMF Policy frame within dot11QMFPolicyChangeTimeout of having transmitted a QMF Policy Change frame with the same dialog token to the STA that transmitted the QMF Policy frame, then the requesting QMF STA shall transmit any subsequently queued Management frames to the peer QMF STA in accordance with the changes to the QMF policy that were indicated in the QMF Policy Change frame.

If a reject status is received in a QMF Policy frame within dot11QMFPolicyChangeTimeout of having transmitted a QMF Policy Change frame with the same dialog token to the STA that transmitted the QMF Policy frame as a response to a QMF Policy Change frame, then the configuration change request is rejected and the requesting QMF STA shall continue to transmit Management frames to the peer QMF STA in accordance with the previously configured QMF policy. The requesting QMF STA shall not transmit a QMF Policy Change frame with a previously rejected QMF policy to a peer QMF STA within dot11QMFPolicyChangeTimeout from the time the requesting STA received the rejection frame.

If the requesting STA does not receive a QMF Policy frame in response to a QMF Policy Change frame within dot11QMFPolicyChangeTimeout, then the requesting STA shall continue to transmit frames according to the previously configured QMF policy.

If a QMF STA has received an Extended Capabilities element with the QMFReconfigurationActivated subfield equal to 0 or has not received an Extended Capabilities element from a destination QMF STA, the QMF STA shall not transmit a QMF Policy Change frame to the destination QMF STA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A QMF mesh STA or a QMF AP may set dot11QMFReconfigurationActivated to true or false. A non-AP QMF STA in an infrastructure BSS shall set dot11QMFReconfigurationActivated to true and shall set the QMFReconfigurationActivated subfield to 1 in transmitted (re)association requests. A non-AP QMF STA with dot11QMFReconfigurationActivated equal to true shall accept any received QMF Policy frame from its associated AP. A QMF STA with dot11QMFReconfigurationActivated equal to false shall respond with a QMF Policy frame, with the current QMF Policy element and Status Code set to REQUEST_DECLINED.

The QMFReconfigurationActivated subfield shall be set to one in the Extended Capabilities element when dot11QMFReconfigurationActivated is true. The QMFReconfigurationActivated subfield shall be set to 0 in the Extended Capabilities element when dot11QMFReconfigurationActivated is false.

The SME of a peer QMF STA uses the MLME-QMFPOLICY primitives to transmit a QMF Policy frame to a peer STA. The SME of a peer STA uses the MLME-QMFPOLICY.request primitive to transmit a QMF Policy frame to a peer STA. The MLME of a peer QMF STA shall set the dialog token to 0 and set the status code to SUCCESS when the QMF Policy frame is transmitted unsolicited to the peer STA.

The SME of a peer QMF STA uses the MLME-QMFPOLICYCHANGE primitives to exchange the QMF Policy Change and QMF Policy frames. The SME of a peer STA uses the MLME-QMFPOLICYCHANGE.request primitive to transmit a QMF Policy Change frame to a peer STA. The value of the dialog token in the MLME-QMFPOLICYCHANGE.request primitive shall be set to a value in the range 1 to 255.

The SME of the peer STA evaluates the QMF policy and uses the MLME-QMFPOLICYCHANGE.response primitive to transmit a QMF Policy frame to the STA including the result of the QMF policy change. The value of the dialog token in the MLME-QMFPOLICYCHANGE.response primitive shall be set to the value of the dialog token received in the corresponding MLME-QMFPOLICYCHANGE.indication primitive.

When the QMF STA SME receives an MLME-QMFPOLICYCHANGE.confirm primitive or MLME-QMFPOLICY.indication primitive with Result Code of SUCCESS, it shall set the new QMF policy using the MLME-QMFPOLICYSET.request primitive.

An AP for which dot11AlternateEDCAActivated is true shall not use the alternate video (A_VI) nor alternate voice (A_VO) transmit queues in its QMF policy.

11.24.2.3 QMF policy configuration in an infrastructure BSS

A QMF AP shall include the QMF Policy element in Beacon frames that it transmits. Non-AP QMF STAs acquire QMF policy configuration information from QMF Policy elements received in Beacon, Association Response, Reassociation Response, Probe Response, and QMF Policy frames. The interpretation of the QMF Policy element is described in 11.24.3.

An associated QMF STA transmitting QMFs shall transmit those frames in accordance with the QMF policy received from its associated AP in the following order of precedence, from highest to lowest:

— QMF policy defined in an unsolicited QMF Policy frame from the associated QMF AP or the QMF Policy Change frame that resulted in a successful response QMF Policy frame from the associated AP, whichever occurred most recently

— QMF policy defined in the QMF Policy element received in the successful (Re)Association Response frame

All unassociated QMF STAs transmitting Management frames to a QMF AP shall transmit those frames to the AP in accordance with the QMF policy in the most recently received Beacon or Probe Response frame from that AP. If no frame containing a QMF Policy element has been received from the AP prior to the transmission of the Management frame(s), then the Management frame(s) shall be transmitted using the access categories of the default QMF policy defined in Table 11-22.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A QMF STA shall transmit all Management frames that are individually addressed to non-QMF STAs using access category AC_VO.

A QMF AP shall set a QMF policy for the transmission of QMFs to its associated STAs. The QMF policy used by the AP for transmission of QMFs to associated STAs is not required to be the same as the QMF policy it advertises.

If the QMFReconfigurationActivated subfield is equal to 1 in the Extended Capabilities element of the Beacon or Probe Response frame transmitted by the AP, an associated QMF STA may use the QMF Policy Change frame to request a change in its existing QMF policy.

11.24.2.4 QMF policy configuration in an IBSS or OCB

QMF STAs in an IBSS or OCB shall use the default QMF policy for all individually addressed Management frames transmitted to other QMF STAs in the IBSS or OCB.

11.24.2.5 QMF policy configuration in an MBSS

A QMF STA operating in an MBSS shall set the QMFActivated subfield in the Extended Capabilities element to true. A mesh STA shall not include a QMF Policy element in a Beacon frame. The QMF in an MBSS policy shall be set on a per link basis between two QMF STAs.

The QMF Policy Change and QMF Policy frames are used by QMF STAs in an MBSS to configure QMF policy. See 11.24.2.2.

A QMF STA shall always accept the QMF policy from the QMF Policy frame transmitted by the peer QMF STA and shall transmit all individually addressed Management frames destined to the peer QMF STA using the received QMF policy.

A QMF STA may request a change in the QMF policy from a peer QMF STA by transmitting a QMF Policy Change to the peer QMF STA. The peer QMF STA may accept or reject this change request. If the peer QMF STA accepts the change, it shall respond with a QMF Policy frame with the Status Code field set to SUCCESS and the QMF STA shall transmit IQMFs using the new QMF policy to the peer QMF STA. If the peer QMF STA rejects the change, it shall respond with QMF Policy frame with the Status Code field set to REQUEST_DECLINED and the QMF STA shall continue transmitting IQMFs according to the previously configured QMF policy.

If a QMF STA does not receive a QMF Policy frame from a peer QMF STA, it shall transmit Management frames to that peer STA using the default QMF policy.

QMF STAs in an MBSS shall not include policies for group addressed Management frames in the QMF Policy Config Request.

11.24.3 Interpreting QMF access categories

The QMF Policy element, as defined in 9.4.2.118, indicates the transmit access categories of different Management frames. A QMF Policy element with Length field of value 1 means that the access category of all Management frames is defined in the default QMF policy in Table 11-22.

When the Individually Addressed subfield is 1, then the QACM applies to IQMFs. When the Group Addressed subfield is 1, then the QACM applies to GQMFs. A STA shall not transmit a QMF Policy element with both the Individually Addressed and Group Addressed subfields set to 0 in any of the included QACM subfields.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The QMF Policy element contains zero or more QACM fields. When included in the QMF Policy element, each QACM field indicates the access category of a group of Management frames. Using the description from Table 11-23, access categories for all Management frames belonging to either a given subtype or a given action category may be indicated in a single QACM field. When multiple Action frames of the same Category are to be mapped to the same Access Category, this is indicated by setting multiple bits in the Action Value Bitmap. For example, setting Bit 0 and Bit 1 indicates Event Request/Response frames when the Management Frame Subtype subfield refers to Management frames of subtype Action and the Category Value subfield refers to the WNM category. The QACM field also may be used to indicate the access category of a single management frame subtype.

Table 11-23—QMF policy description for valid combination of optional fields in the QACM field

QACM field Length subfield	Action frame category	Action Value Bitmap subfield	Description
0	Not included	Not included	Policy to be applied to all Management frames of the corresponding subtype
1	Included	Not included	Policy to be applied to all Action frames of corresponding category value
≥ 2	Included	Included	Policy to be applied only to Action frames indicated via the action value bitmap for Management frames of the subtype indicated in the Management Frame Subtype subfield and the category value indicated in the Action Frame Category subfield in the corresponding QACM field

A QMF STA that received a QMF Policy element from its associated QMF AP shall discard any previously received QMF Policy elements. If a Management frame is indicated in multiple QACM fields, the access category of the Management frame is determined by the access category defined in the last QACM field in the QMF Policy that contains the access category assignment of the corresponding Management frame. For example, if an QACM field sets the entire WNM category to access category AC_BE and a later QACM field sets Event Request/Report of WNM category to AC_BK, then all Action frames of WNM category are transmitted using access category AC_BE with the exception of Event Requests/Reports, which are transmitted using access category AC_BK.

11.25 Robust AV streaming

11.25.1 Robust AV streaming dependencies

When dot11RobustAVStreamingImplemented is true, the STA is a robust AV streaming STA. The attribute dot11QosOptionImplemented shall be true in a robust AV streaming STA.

11.25.2 SCS procedures

The stream classification service (SCS) is a service that may be provided by an AP to its associated STAs that support SCS. In SCS, the AP classifies incoming individually addressed MSDUs based upon parameters provided by the non-AP STA.

The classification allows the UP, drop eligibility, and EDCA transmit queue to be selected for all MSDUs matching the classification.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Implementation of SCS is optional for a STA. A STA that implements SCS shall set its dot11SCSImplemented to true. A STA with dot11SCSActivated equal to true shall support stream classification and shall set to 1 the SCS field of the Extended Capabilities elements that it transmits. If dot11SCSActivated is true, dot11SCSImplemented shall be true.

A non-AP STA that supports SCS may request use of SCS by sending an SCS Request frame that includes an SCS Descriptor element with the Request Type field set to "Add" or "Change." The SCS Descriptor List field in the SCS Descriptor element identifies how MSDUs are classified and the priority to assign to MSDUs that match this classification.

Each SCS stream is identified by an SCSID. This SCSID is used by a non-AP STA to request creation, modification, or deletion of an SCS stream. The SCSID is used by an AP to identify an SCS stream in SCS responses.

Upon receipt of an SCS Request frame from an associated non-AP STA, the AP shall respond with a corresponding SCS Response frame. A value of SUCCESS shall be set in the corresponding Status field of the SCS Status duple in the SCS Response frame when the AP accepts the SCS request for the requested SCSID. A value of REQUEST_DECLINED, REQUESTED_TCLAS_NOT_SUPPORTED_BY_AP, or INSUFFICIENT_TCLAS_PROCESSING_RESOURCES shall be set in the corresponding SCS Status field of the SCS Status duple in the SCS Response frame when the AP denies the SCS request for the requested SCSID.

If the AP declines a request to change a previously accepted SCSID, the previously accepted classification for this SCSID continues to operate.

If the requested SCS is accepted by the AP, the AP shall process subsequent incoming individually addressed MSDUs from the DS or WM that match the TCLAS elements and optional TCLAS Processing element classifier specified in the SCS Descriptor element.

If an MSDU matches the classifier specified in the SCS Descriptor elements of multiple SCS streams, the SCS Descriptor element that specifies the greatest number of classifier parameters required for a match (i.e., the most granular classifier) is used. If an MSDU matches the classifier specified in SCS Descriptor elements that specify the same number of classifier parameters, which classifier is used is implementation dependent.

The number of classifier parameters required for a match in a given TCLAS element is 1 when the Classifier Type is 2, 3 or 10, and is 3 when the Classifier Type is 5. For other classifier types, the Classifier Mask field indicates which classifier parameters are required for a match. For Classifier Types 1 and 4, the (IP) Version classifier parameter is not counted when determining the number of classifier parameters required for a match. Reserved fields are not classifier parameters.

If multiple TCLAS elements are included in an SCS Descriptor element, the number of classifier parameters required for a match is the sum of the number of classifier parameters required for a match for each TCLAS element if the Processing field in the TCLAS Processing element is 0, or is the minimum of the number of classifier parameters required for a match for each TCLAS element if the Processing field is 1. If a TCLAS Processing element is included where the Processing field is 2, the number of classifier parameters required for a match is 0.

A STA should not request creation of multiple SCS streams that might match the same MSDU and specify the same number of classifier parameters.

A match of the classifier is defined as follows:

— When the Processing field of the TCLAS Processing element is 0, the classifier matches all of the parameters in the TCLAS elements in the SCS Descriptor element.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— When the Processing field of the TCLAS Processing element is 1 or the TCLAS Processing element is not present, the classifier matches if the parameters match at least one of the TCLAS elements in the SCS Descriptor element.

The processing of matching MSDUs depends upon the access policy assigned to the MSDU:

— For matching MSDUs that are not part of a TS (as described in 11.4), the User Priority subfield of the Intra-Access Category Priority element is used as the UP of these MSDUs.
— For matching MSDUs that are part of a TS (as described in 11.4), the TID and UP classification of these MSDUs shall follow the rules specified in 11.4.7.
— If dot11AlternateEDCAActivated is true, for matching MSDUs that are not part of a TS (as described in 11.4) or for MSDUs that are part of a TS that uses EDCA or HEMM as the access policy, the Alternate Queue subfield of the Intra-Access Category Priority element is used to select whether the primary EDCA transmit queue or alternate EDCA transmit queue is used for these MSDUs.
— All matching MSDUs have their DEI set using the value from the Drop Eligibility subfield of the Intra-Access Category Priority element in the DEI subfield of the HT Control field, as defined in 9.2.4.6.

A non-AP STA may request the termination of an accepted SCS stream by sending an SCS Request frame with the Request Type field set to “Remove” and the requested SCSIDs in the SCS Descriptor element. No Intra-Access Priority, TCLAS, or TCLAS Processing elements shall be included in the SCS Descriptor element.

Upon reception of an SCS Request frame that requests termination of an SCS stream, the AP shall send an SCS Response frame with the Dialog Token and SCSID fields set to the corresponding fields in the SCS Request frame and the Status field set to TCLAS_PROCESSING_TERMINATED.

The AP may use the MLME-SCS-TERM.request primitive to send an unsolicited SCS Response frame at any time to terminate an SCS stream. The AP shall set the Dialog Token field to 0, the SCSID field to identify the SCS stream being terminated, and the Status field to TCLAS_PROCESSING_TERMINATED, TCLAS_PROCESSING_TERMINATED_INSUFFICIENT_QOS, TCLAS_PROCESSING_TERMINATED_POLICY_CONFLICT, or TCLAS _RESOURCES_EXHAUSTED.

When an SCS stream is terminated, the AP shall cease to apply the classifier(s) related to it.

11.25.3 MSCS procedures

The mirrored stream classification service (MSCS) is a service that may be provided by an AP to its associated STAs that support MSCS. In MSCS, the AP classifies incoming individually addressed MSDUs from the DS or WM that are destined for a non-AP STA based upon classifier masks provided by that non-AP STA. The AP sets the UP of the MSDUs in the classified streams based on the UP of individually addressed MSDUs in the corresponding mirror (reverse direction) stream from the non-AP STA to the AP.

Implementation of MSCS is optional for a STA. A STA that supports MSCS sets its dot11MSCSActivated to true, and shall set to 1 the Mirrored SCS field of the Extended Capabilities elements that it transmits. When dot11MSCSActivated is true, dot11QosOptionImplemented shall be true.

An MSCS setup is initiated by a non-AP STA’s SME. How it does this, and how it selects the MSCS Descriptor parameter, is out of scope of this standard. Setup of an MSCS uses the MLME-MSCS.request, MLME-MSCS.indication, MLME-MSCS.response and MLME-MSCS.confirm primitives (see 6.3.2).

A non-AP STA that supports MSCS may request use of MSCS, or request to update parameters of the currently active MSCS, by sending an MSCS Request frame that includes an MSCS Descriptor element with the Request

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Type field set to “Add” or “Change”, respectively. A non-AP STA that supports MSCS may request use of MSCS by sending a (Re)Association Request frame that includes an MSCS Descriptor element with the Request Type field set to “Add”. The MSCS Descriptor element identifies how MSDUs are classified into streams and indicates parameters that determine the priority to assign to the classified MSDUs.

In a TCLAS Mask element in an MSCS Descriptor element, the Classifier Type subfield shall be set to a value that corresponds to a classifier of MSDUs, i.e., less than or equal to 5, or equal to 10.

Upon receipt of an MSCS Request frame from an associated non-AP STA, or receipt from a non-AP STA of a (Re)Association Request frame containing an MSCS Descriptor element, the AP shall respond with a corresponding MSCS Response frame or with a (Re)Association Response frame containing an MSCS Descriptor element, respectively. When the AP accepts the MSCS request in response to an MSCS Request frame, it shall set the Status field in the MSCS Response frame to “SUCCESS” and shall not include an MSCS Descriptor element in the frame. When the AP accepts the MSCS request in response to a (Re)Association Request frame, it shall set the Status field in the MSCS Status subelement of the MSCS Descriptor element of the (Re)Association Response frame to “SUCCESS” and set the Request Type field to “Add”.

A value of REQUEST_DECLINED, REQUESTED_TCLAS_NOT_SUPPORTED_BY_AP, or INSUFFICIENT_TCLAS_PROCESSING_RESOURCES shall be set in the Status field in the MSCS Response frame or in the MSCS Status subelement of the MSCS Descriptor element of the (Re)Association Response frame, when the AP declines the MSCS request; an MSCS Descriptor element is optionally present in the MSCS Response frame for this case. If an MSCS Descriptor element is present in an MSCS Response frame that does not indicate a status of “SUCCESS”, the Request Type field is set to “Change” and the element indicates a suggested set of parameters that could be accepted by the AP in response to a subsequent request by the non-AP STA. In the MSCS Descriptor element of a (Re)Association Response frame with a value in the Status field other than “SUCCESS” the Request Type field is set to “Add” if no suggested set of parameters is indicated, or set to “Change” if the element indicates a suggested set of parameters that could be accepted by the AP in response to a subsequent request by the non-AP.

When the AP does not accept an MSCS request in response to an MSCS Request frame with a Request Type field value of “Change”, the existing MSCS is unchanged.

An AP has a maximum of one active MSCS per non-AP STA. A non-AP STA shall not send an MSCS request to an AP with the Request Type field set to “Add” if MSCS is currently active with that AP.

If MSCS for a non-AP STA is currently active and the AP declines an MSCS request from the non-AP STA with Request Type field set to “Change”, the previously accepted parameters continue to apply.

If the request is accepted by the AP, MSCS for the non-AP STA becomes active. Incoming MSDUs whose DA parameter value maps to an RA equal to the MAC address of the non-AP STA are classified above the AP’s MAC sublayer and are sent to the MAC through the MAC SAP using the MA-UNITDATA.request primitive with the priority parameter equal to the assigned UP, based on the parameters specified in the MSCS Descriptor element. The following procedure is used:

a) The classifier parameters and associated masks of the MSCS are determined according to the TCLAS Mask element(s) in the MSCS Descriptor element as follows:
   — For TCLAS Mask elements indicating a classifier type value less than or equal to 5, but not equal to 3, the classifier parameters specified by that element are indicated by the Classifier Mask subfield; there is no associated mask for these parameters.
   — For TCLAS Mask elements indicating classifier type 3, the classifier parameter specified by that element is equal to the set of octets defined by the Filter Offset subfield and length of the (reserved) Filter Value subfield; the associated mask for the parameter is specified in the Filter Mask subfield.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— For TCLAS Mask elements indicating classifier type 10, the classifier specified by that element is equal to the set of octets defined by the Protocol Number or Next Header subfield and the length of the (reserved) Filter Value subfield; the associated mask for the parameter is specified in the Filter Mask subfield.

— The classifier parameters and associated masks of the MSCS comprise all the classifier parameters and associated masks specified by all the TCLAS Mask elements in the MSCS Descriptor element.

b) The mirror classifier parameters and associated masks are determined as follows:

— If source (Ethernet) address is a classifier parameter, destination (Ethernet) address is a mirror classifier parameter; there is no associated mask for this parameter.

— If destination (Ethernet) address is a classifier parameter, source (Ethernet) address is a mirror classifier parameter; there is no associated mask for this parameter.

— If source IP address is a classifier parameter, destination IP address is a mirror classifier parameter; there is no associated mask for this parameter.

— If destination IP address is a classifier parameter, source IP address is a mirror classifier parameter; there is no associated mask for this parameter.

— If source port is a classifier parameter, destination port is a mirror classifier parameter; there is no associated mask for this parameter.

— If destination port is a classifier parameter, source port is a mirror classifier parameter; there is no associated mask for this parameter.

— If any other parameter is a classifier parameter, the same parameter is a mirror classifier parameter; if the classifier parameter has an associated mask then the mirror classifier parameter has the same associated mask.

c) A logical list is maintained, initially empty, of variables *UP{tuple}*, where each variable represents a user priority associated with a value *tuple* of the masked classifier parameters. Monitoring of incoming individually addressed MSDUs as indicated by the MA-UNITDATA.indication primitive begins. If an MSDU is received that is not part of a TS (as described in 11.4) and the SA parameter value is equal to the MAC address of the non-AP STA and the priority parameter is equal to an integer value in the range 0 to 7 and the service class parameter is equal to QoSAck, the MSDU's UP is determined per 5.1.1.3 and, if the UP is equal to one of the UPs specified in the User Priority bitmap subfield of the MSCS Descriptor element, the following steps are performed:

1) Determine *m_tuple* of the received MSDU, which is equal to the tuple of all mirror classifier parameters of the MSDU masked by the associated masks (see item b) above). If the MSDU has no value for one or more of the mirror classifier parameters, the remaining steps are not performed.

2) Determine *tuple* corresponding to the received MSDU, by mapping all the masked values of parameters in *m_tuple* per the relationships described in item b) above.

3) Add or update the variable *UP{tuple}* in the list, setting the value of the variable to the UP of the received MSDU. When a variable is updated (i.e., when a variable corresponding to the same *tuple* already exists in the list), the previous value of the variable is discarded.

If a period equal to the value of the Stream Timeout subfield of the MSCS Descriptor element has elapsed since a given variable in the list was last updated, that variable may be removed from its maintained list.

d) In parallel, classification begins of incoming MSDUs from the DS or WM whose DA parameter value maps to an RA equal to the MAC address of the non-AP STA. The following steps are performed for each such MSDU:

1) Determine *tuple* of the MSDU, which is equal to the tuple of all the classifier parameters of the MSDU masked by the associated masks (see (a) above). If the MSDU does not have a value for one or more of the classifier parameters, the remaining steps are not performed.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

2) If variable *UP{tuple}* exists in the list for this value of *tuple*, and the MSDU is not part of a TS (as described in 11.4), and the MSDU is not part of an SCS stream (see 11.25.2), assign the MSDU a UP equal to min(*UP{tuple}, UPLim*), where *UPLim* is the value of the User Priority Limit subfield of the MSCS Descriptor element.

NOTE 1—The maintenance of the logical list of variables *UP{tuple}* described above is a logical description of a required process. The specific implementation of this process is vendor specific and is not required to match the description above.

NOTE 2—When MSCS does not assign a UP to an MSDU that is not part of a TS or an SCS stream, the UP of the MSDU might be set by other mechanisms such as interworking QoS mapping from DSCP values (e.g., see R.3).

NOTE 3—It is recommended that a non-AP STA using MSCS sets the UP of MSDUs it transmits to its associated AP in a way that does not cause the variables *UP{tuple}* maintained by the AP to change excessively often. This helps to minimize management overhead on the AP, and also minimizes the possibility of MSDUs with the same value of *tuple* being delivered to the higher layers out of order during the transition of the UP of those MSDUs. Note that the requirements for ordering of MSDUs with the same TID value in the MAC sublayer (see 5.1.3) are unaffected by MSCS.

A non-AP STA may request the termination of a currently active MSCS by sending an MSCS Request frame with the Request Type field set to “Remove” in the MSCS Descriptor element. Upon reception of a request to terminate the active MSCS, the AP shall cease to apply the corresponding classifiers and processing related to the active MSCS and delete the maintained list of variables *UP{tuple}*. The AP shall send an MSCS Response frame to confirm the termination of the MSCS, by including a value of “TCLAS_PROCESSING_TERMINATED” in the Status field of an MSCS Response frame and the dialog token in the MSCS Response frame set to the value from the MSCS Request frame that requested termination; an MSCS Descriptor element is not present in the response.

The AP may send an unsolicited MSCS Response frame at any time to cancel an active MSCS, by including a value of “TCLAS_PROCESSING_TERMINATED”, “TCLAS_PROCESSING_TERMINATED_INSUFFICIENT_QOS”, “TCLAS_PROCESSING_TERMINATED_POLICY_CONFLICT” or “TCLAS_RESOURCES_EXHAUSTED” in the Status field of an MSCS Response frame and the dialog token in the MSCS Response frame set to 0. The MSCS Descriptor element is optionally present; if present the Request Type field is set to “Change” and the element indicates a suggested set of parameters that could be accepted by the AP in response to a subsequent request by the recipient non-AP STA.

11.26 Procedures to manage OBSS

11.26.1 General

QLoad Report elements, HCCA TXOP Update Count elements, HCCA TXOP Advertisement action frames, and HCCA TXOP Response frames are designed to mitigate the effects of OBSSs and provide the means to

- Advertise QoS load information for channel selection
- Extend the admission control and scheduled mechanisms to a distributed environment
- Enable the coordination of scheduled HCCA TXOPs between HCs operating with OBSSs

OBSS APs are APs that are using the same primary channel and that are able to receive or obtain frames from each other, including Beacon frames. These frames are received directly or via associated STAs that support the Beacon request capability (as indicated by the Beacon Passive Measurement Capability Enabled bit or the Beacon Active Measurement Capability Enabled bit being set in the RM Enabled Capabilities element in the (Re)Association Request frame). An AP might scan other channels as part of its channel selection process or might request associated STAs that support the Beacon request capability to perform an off-channel Beacon request measurement, and these procedures might provide QLoad Report elements received from APs

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

operating on other channels. Subclause T.3 provides an example of using QLoad Reports from adjacent channels.

NOTE 1—These OBSS procedures might use unauthenticated Beacon frames and Public Action frames. Implementations might choose to use additional heuristics (e.g., a history of collaboration and traffic monitoring) to determine the authenticity of this information.

NOTE 2—These OBSS procedures are intended for stationary and portable APs (see 4.2.4).

11.26.2 QLoad Report element

11.26.2.1 Introduction

The QLoad Report element is contained in QLoad Report frames or Protected QLoad Report frames that are provided by an AP and, optionally, periodically in the Beacon frame. The QLoad Report frame is transmitted, upon the receipt of a QLoad Request frame by an AP for which dot11QLoadReportActivated is true, to the STA that sent the QLoad Request frame. An AP shall not send a QLoad Request frame or Protected QLoad Request frame to another AP that has QLoad Report field set to 0 in its Extended Capabilities element. The Protected QLoad Report frame is transmitted, upon the receipt of a Protected QLoad Request frame when dot11ProtectedQLoadReportActivated is true, to the STA that sent the Protected QLoad Request frame. An AP for which dot11ProtectedQLoadReportActivated is false shall discard any received Protected QLoad Request or Protected QLoad Report frames.

Whenever there is a change in the contents of the QLoad Report element and there is no pending delay period for an unsolicited QLoad Report frame, an unsolicited QLoad Report frame should be transmitted with the RA field set to the broadcast address, after a randomly selected delay between 1 and dot11QLoadReportDelay seconds. After this delay, the AP shall transmit an unsolicited QLoad Report frame that contains the most recently available QLoad information. When dot11QLoadReportActivated is true, the QLoad Report element shall be included in the Beacon frame every dot11QLoadReportIntervalDTIM DTIM intervals. When dot11QLoadReportActivated is false, the QLoad Report element shall not be included in Beacon frames.

11.26.2.2 Calculating field values

The value of the Potential Traffic Self field represents the potential QoS traffic of this BSS; therefore, the value in the Mean subfield shall always be greater than or equal to the value of the Mean subfield in the Allocated Traffic Self field.

The AP shall include in the Allocated Traffic Self field all accepted and not deleted TSPECs as they are sent by non-AP STAs. At the deletion of each such TSPEC, the AP shall remove the TSPEC from its Allocated Traffic Self field.

The number of active AC_VI and AC_VO streams shall be provided in the Allocated Traffic Self field. For each admitted admission control TSPEC, the AP calculates a medium time, as described in K.2.2. This medium time, however, does not include the medium access overhead that, in turn, is related to the number of streams. This access overhead is further discussed in T.2.7, and a recommendation is given for its value.

An example of a method of calculating the values for the Mean and Standard Deviation subfields in the Potential Traffic Self field is given in T.2.3.

The Sharing Policy field is used to indicate the currently active policy for sharing the medium with OBSSs. Setting the Sharing Policy field to “Static” indicates that the share of the total available medium time of an AP does not change when the value of the Allocated Traffic Shared field changes. Setting the Sharing Policy field to “Dynamic” indicates that the share of the total available medium time of an AP might change when the value

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

of the Allocated Traffic Shared field changes. If the Sharing Policy field has the value "Vendor Specific," then the QLoad Report element shall contain a Vendor Specific subelement.

If the value of the Overlap field changes, the share of the total available medium time of an AP might change for both static and dynamic sharing policies.

The value of the Potential Traffic Self field represents the potential QoS traffic of this AP and, therefore, shall always be greater than or equal to the values represented by the Allocated Traffic Self field.

The Allocated Traffic Self field contains the mean and standard deviation values of the total EDCA admission control and HCCA traffic that the AP has allocated at any one time and contains the number of AC_VI and AC_VO EDCA admission control streams. As each stream is added or deleted, the AP shall calculate the new value of the Allocated Traffic Self field. A recommended method for calculating the Allocated Traffic Self field mean and standard deviation values is given in T.2.4.

The Allocated Traffic Shared field is calculated from the Allocated Traffic Self fields for all APs that overlap with the AP performing the calculation, including the Allocated Traffic Self field of the AP performing the calculation. A recommended method for summing the Allocated Traffic Self field values is given in T.2.4.

The EDCA Access Factor is the total traffic bandwidth requirement for all of the OBSSs expressed as a fraction that may be greater than 1. An implementation might calculate the EDCA Access Factor from the summation of the Potential Traffic Self field values of all of the APs that are overlapping, as follows:

a) Sum all of the Potential Traffic Self field values for all OBSSs, including self, in order to calculate the peak traffic requirement in multiples of 32 μs/s. As the Potential Traffic Self field value is expressed in terms of mean and standard deviations, it is possible to sum the Potential Traffic Self field values as a composite stream. A suggested method for this summation is given in T.2.3.
b) Sum all of the HCCA Peak field values from all OBSSs, including self, in order to calculate the peak HCCA traffic requirement, in multiples of 32 μs/s.
c) Subtract the value derived in step b) from the value derived in step a). This value is the EDCA traffic.
d) Sum the AC_VO and AC_VI streams reported in its own QLoad report and all of the QLoad reports of OBSSs. Based upon the number of EDCA streams, an EDCA Overhead Factor can be estimated to account for the medium access time requirements. EDCA Overhead Factor is further discussed in T.2.3, and a recommendation is given for its value.
e) Multiply together the EDCA traffic from step c) and the EDCA Overhead Factor to obtain a value that represents the total peak bandwidth requirement for the OBSSs. This value is in multiples of 32 μs/s.
f) Convert the total peak bandwidth requirement to a fraction that is rounded down to a multiple of 1/64 (8 bits). This value is the EDCA Access Factor. An example for this conversion is given in T.2.6.

The HCCA Peak field value is the sum of the all of the medium times of active TS that use the HCCA or HEMM access policy over a 1 s period for all of the HCCA TSPECs included in the QLoad field. The TXOP time, scheduled by the HC, multiplied by the reciprocal of its SI, is termed the *HCCA medium time*. The HCCA Peak field value is the summation of the HCCA medium times that the HC has scheduled, in multiples of 32 μs.

The HCCA Access Factor is the total HCCA TXOP medium time requirement for all of the OBSSs expressed as a fraction that may be greater than 1. An implementation might calculate the HCCA Access Factor from the summation of the HCCA Peak field values of all of the APs that in an OBSS, by summation of all of the HCCA Peak field values for all APs in OBSSs and converting this summation to a fraction that is rounded down to 1/64 (8 bits). An example for this conversion is given in T.2.8.

11.26.2.3 Requesting QLoad Reports using radio measurement requests

If an AP has associated STAs that support passive or active beacon measurement (as indicated by the Beacon Passive Measurement Capability Enabled bit or the Beacon Active Measurement Capability Enabled bit being set in the RM Enabled Capabilities element), it may use the neighbor report capability of these associated STAs to attempt to retrieve QLoad Report elements from APs with which the AP is unable to exchange frames directly.

The AP sends a Radio Measurement Request frame that contains a Measurement Request element to an associated STA that supports neighbor reporting and beacon reporting. This Measurement Request element has the Measurement Type field set to "Beacon request" (as defined in Table 9-136), and the BSSID field of the Measurement Request field of the Beacon request frame (as defined in Figure 9-250) is set to the wildcard BSSID. There shall be a Request subelement in the Measurement Request field of the Beacon request frame that contains the Element ID of the QLoad Report element (as defined in Table 9-130) and may contain other element IDs. The SSID subelement shall not be included in the Request subelement of the Measurement Request field of the Beacon request.

Depending upon the signaled enabled radio measurement capabilities of the associated STA, the AP may use either the passive or active measurement mode. The Channel Number field should be set to the primary channel number that is currently being used by the AP, but may be set to other values if off-channel beacon measurement is supported by the STA to which the measurement request is to be sent.

If the measurement request is accepted, the requested STA performs the measurement request (as described in 11.10). The subsequent Radio Measurement Report frame contains Beacon reports for successful measurements. These Beacon reports might contain QLoad Report elements inside a Reported Frame Body subelement, if the reporting STA received QLoad Report elements from the Beacon or Probe Response frames that it received from neighboring APs. The contents of these QLoad Report elements can then be used in calculating Allocated Traffic Shared, EDCA Access Factor, and HCCA Access Factor field values as described in 11.26.2.2.

11.26.3 HCCA TXOP negotiation

The procedures described in this subclause allow HCCA APs to cooperatively create new HCCA schedules that do not collide.

When sharing with at least one other HCCA AP, each sharing AP for which dot11RobustAVStreamingImplemented is true shall set its dot11HCCWmax to a value of at least 3.

HCCA APs that are able to directly exchange frames without the use of a third-party STA and signal support for unprotected or protected TXOP negotiation (as indicated by the Unprotected TXOP Negotiation or Protected TXOP Negotiation field equal to 1 in the Extended Capabilities element in Beacon frames) coordinate their TXOP schedules using HCCA TXOP Advertisement and HCCA TXOP Response frames. In this subclause, an HCCA AP in an OBSS that is able to directly exchange frames without the use of a third-party STA is referred to as a *collaboration candidate*.

The HCCA TXOP Update Count element is included in the Beacon frame to indicate that an HCCA TXOP schedule has changed. The Update Count field of the HCCA TXOP Update Count element is incremented (modulo 256) each time a TS with an access policy of HCCA or HEMM is created or deleted. An HCCA AP for which dot11PublicHCCATXOPNegotiationActivated is true or dot11ProtectedHCCATXOPNegotiationActivated is true shall advertise the Duration, Service Interval, and Start Time subfields for each HCCA TXOP reservation in a TXOP Reservation field as described in 9.4.1.41.

An HCCA AP for which dot11PublicTXOPNegotiationActivated is true or dot11ProtectedTXOPNegotiationActivated is true shall support maintaining one or more dot11APCEntry(s)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

for each collaboration candidate in the dot11APCTable. These fields indicate the schedules that the AP should try to avoid using when creating schedules for new TS requests.

Before accepting a TSPEC request that has the Access Policy subfield of the TSPEC element equal to "HCCA" or "HEMM," an HC for which dot11PublicTXOPNegotiationActivated is true or dot11ProtectedTXOPNegotiationActivated is true should examine all dot11APCEntry(s) that are present in the dot11APCTable.

When an AP with dot11PublicHCCATXOPNegotiationActivated true or with dot11ProtectedHCCATXOPNegotiationActivated true receives a TSPEC request that has the Access Policy subfield of the TSPEC element equal to "HCCA" or "HEMM," it shall send an HCCA TXOP advertisement to each collaboration candidate. These HCCA TXOP advertisements shall have the TXOP Reservation field set to the TXOP that the AP is attempting to schedule.

An AP with dot11ProtectedTXOPNegotiationActivated true shall send the HCCA TXOP advertisement using a Protected HCCA TXOP Advertisement frame to each collaboration candidate that indicates support for protected HCCA TXOP negotiation (as indicated by the Protected TXOP Negotiation field equal to 1 in the Extended Capabilities element in Beacon frames from the collaboration candidate).

An AP with dot11PublicTXOPNegotiationActivated true shall send the HCCA TXOP advertisement using an HCCA TXOP Advertisement frame to each collaboration candidate that indicates support for unprotected HCCA TXOP negotiation (as indicated by the Unprotected TXOP Negotiation field equal to 1 in the Extended Capabilities element in Beacon frames from the collaboration candidate) unless the HCCA TXOP advertisement has already been transmitted to this collaboration candidate using a Protected HCCA TXOP Advertisement frame.

NOTE—When peer APs have both unprotected and protected TXOP negotiation activated, protected TXOP negotiation is used.

The AP shall not send an ADDTS Response frame to the requesting STA until one of the following conditions occurs:

a) The AP has received an HCCA TXOP Response frame, with the Status field equal to SUCCESS, from all of the APs to which HCCA TXOP advertisements were sent.
b) At least two Beacon frames have been received from all of the APs to which HCCA TXOP advertisements were sent.
c) A Beacon frame containing the HCCA TXOP Update Count element is received from all of the APs to which HCCA TXOP advertisements were sent.
d) A period of three dot11BeaconPeriod TU has elapsed.

If an AP receives another TSPEC request while waiting for one of the above conditions to occur, it shall delay processing this additional TSPEC request until one of the above conditions occurs.

An AP with dot11PublicTXOPNegotiationActivated false shall discard any received HCCA TXOP Advertisement frames. An AP with dot11ProtectedTXOPNegotiationActivated true shall discard any received unprotected HCCA TXOP Advertisement frames from a peer AP with which it has an active security association.

Upon reception of an unprotected HCCA TXOP Advertisement frame, an AP with dot11PublicTXOPNegotiationActivated true shall discard all dot11APCEntry(s) from the dot11APCTable that have dot11APCEntryMACAddress equal to the MAC address of the AP that sent the HCCA TXOP Advertisement frame and shall prepare a response using the procedures below.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An AP with dot11ProtectedTXOPNegotiationActivated false shall discard any received Protected HCCA TXOP Advertisement frames.

An AP with dot11ProtectedTXOPNegotiationActivated true that does not have an active security association with a peer AP that indicates support for protected HCCA TXOP negotiation shall use the AP PeerKey protocol (as defined in 12.10.2) and authenticated mesh peering exchange (AMPE) (as defined in 14.6) to negotiate security parameters and create a new PMKSA and PTKSA to secure the Protected HCCA TXOP Advertisement frames. The use of AMPE proves possession of the PMK (generated using the procedures described in 12.10.2) and implicitly the private key that corresponds to the peer's public key.

Upon reception of a valid Protected HCCA TXOP Advertisement frame, an AP with dot11ProtectedTXOPNegotiationActivated true shall discard all dot11APCEntry(s) from the dot11APCTable that have dot11APCEntryMACAddress equal to the MAC address of the AP that sent the Protected HCCA TXOP Advertisement frame and shall prepare a response using the procedures below.

If the (Protected) HCCA TXOP Advertisement frame has not been discarded due to the procedures above, the AP shall create a dot11APCEntry in the dot11APCTable for each TXOP reservation in the Active TXOP Reservations field of the (Protected) HCCA TXOP Advertisement frame.

If the (Protected) HCCA TXOP Advertisement frame has not been discarded due to the procedures above, the AP shall inspect its HCCA schedule to check whether the TXOP reservations number given in the Pending TXOP Reservations field of the HCCA TXOP Advertisement frame is in conflict with an existing accepted HCCA TXOP, allocated by itself. If there is no conflict, the AP shall send an HCCA TXOP Response frame with the Status field set to SUCCESS and create a dot11APCEntry for each TXOP reservation in the Pending TXOP Reservations field in the HCCA TXOP Advertisement frame.

If the HCCA advertisement was sent using an unprotected Public Action frame, the HCCA TXOP response shall be sent using an unprotected Public Action frame.

If the HCCA advertisement was sent using a Protected HCCA TXOP Advertisement frame, the HCCA TXOP response shall be sent using a Protected HCCA TXOP Response frame.

If the AP detects that the TXOP given in the (Protected) HCCA TXOP Advertisement frame is in conflict with an existing accepted HCCA TXOP and this AP is not itself currently processing an ADDTS request, it shall send a (Protected) HCCA TXOP Response frame with the Status field set to "TS_SCHEDULE_CONFLICT," the Alternate Schedule field set to a period of time that does not conflict with any currently accepted HCCA TXOPs, and the Avoidance Request field absent. The Duration subfield of the Alternate Schedule field should be greater than or equal to the Duration subfield of the Schedule field in the (Protected) HCCA TXOP Advertisement frame. The Duration subfield of the Alternate Schedule field may be less than the Duration subfield of the Schedule field in the (Protected) HCCA TXOP Advertisement frame when there is an insufficient period of time that does not conflict with currently accepted HCCA TXOPs.

If the AP detects that the TXOP given in the (Protected) HCCA TXOP Advertisement frame is in conflict with an in-progress ADDTS request for an HCCA TXOP for which HCCA TXOP Response frames have not been received, it shall send a (Protected) HCCA TXOP Response frame with the Status field set to "TS_SCHEDULE_CONFLICT" and the Alternate Schedule and Avoidance Request fields set according to the following rules:

— If MIX(MAC_r) < MIX(MAC_i), the Alternate Schedule field is set to a value that does not conflict with any accepted HCCA TXOPs and also does not conflict with the TXOP of the in-progress ADDTS request. The Avoidance Request field is set to the TXOP of the in-progress ADDTS request.
— If MIX(MAC_r) > MIX(MAC_i), the Alternate Schedule field is set to the value from the TXOP Reservation field from the HCCA TXOP Advertisement frame. The Avoidance Request field is set

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

to a time period that does not conflict with any accepted HCCA TXOPs nor the TXOP in the Alternate Schedule field and has sufficient duration and service interval to meet the requirements of the in-progress ADDTS request.

where

MAC_r is the MAC address of the AP that received the HCCA TXOP Advertisement frame

MAC_i is the MAC address of the AP that sent the HCCA TXOP Advertisement frame

The MIX function takes the 6 octets of a MAC address and computes a new 6-octet value:

MIX(MAC) = MAC[4] || MAC[5] || MAC[0] || MAC[1] || MAC[2] || MAC[3]

For the purpose of the comparisons shown above, the resulting 6-octet value is converted to a positive integer treating the first octet as the most significant octet of the integer.

Table 11-24 provides a summary of the values used in an HCCA TXOP Response frame.

Table 11-24—Contents of HCCA TXOP Response frame

Case	Status code	Alternate Schedule field	Avoidance Request field
No conflict with existing or in-progress schedules	SUCCESS	Not present	Not Present
Conflicts with existing schedule; no ADDTS request in progress	TS_SCHEDULE_ CONFLICT	Period of time that does not conflict with any currently accepted HCCA TXOPs	Not Present
Conflict with in-progress schedules, MIX(MAC_r) < MIX(MAC_i)	TS_SCHEDULE_ CONFLICT	Period of time that does not conflict with any currently accepted HCCA TXOPs nor the in-progress ADDTS request	Schedule of in-progress ADDTS request
Conflict with in-progress schedules, MIX(MAC_r) > MIX(MAC_i)	TS_SCHEDULE_ CONFLICT	Same schedule that was in the HCCA TXOP Advertisement frame	Period of time that does not conflict with any currently accepted HCCA TXOPs nor the period given in the Alternate Schedule field

The AP shall keep a record of the TXOP proposed in the Alternate Schedule field in a TXOP avoidance record and should avoid scheduling any new HCCA TXOPs in this proposed period until any of the following conditions occurs:

— A period of dot11HCCATXOPBeaconTimeout multiplied by dot11BeaconPeriod TUs has elapsed.

— The AP with dot11PublicTXOPNegotiationActivated true receives an unprotected HCCA TXOP Advertisement frame from the AP to which the unprotected HCCA TXOP Response frame was sent.

— The AP with dot11ProtectedTXOPNegotiationActivated true receives a Protected HCCA TXOP Advertisement frame from the AP to which the Protected HCCA TXOP Response frame was sent.

If an AP with dot11PublicTXOPNegotiationActivated true receives an unprotected HCCA TXOP Response frame with the Status field equal to "TS_SCHEDULE_CONFLICT," the AP should create a new schedule for the TSPEC request using the suggestion provided in the HCCA TXOP Response frame. If an AP with

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

dot11ProtectedTXOPNegotiationActivated true receives a Protected HCCA TXOP Response frame with the Status field equal to "TS_SCHEDULE_CONFLICT," the AP should create a new schedule for the TSPEC request using the suggestion provided in the Protected HCCA TXOP Response frame.

If an AP creates a new schedule in response to a (Protected) HCCA TXOP Response frame, it shall send a new HCCA TXOP advertisement to each collaboration candidate, using the procedures previously defined in this subclause.

After one or more HCCA TXOP Advertisement frame transmissions that cause the reception of an HCCA TXOP Response frame with the Status field equal to "TS_SCHEDULE_CONFLICT," the AP may terminate the HCCA TXOP advertisement procedure and respond to the ADDTS Request frame with a status code not equal to SUCCESS (decline the ADDTS Request) or a status code equal to SUCCESS (accept the ADDTS request regardless of potential HCCA TXOP conflicts).

11.26.4 HCCA AP timing synchronization for HCCA TXOP advertisement

11.26.4.1 General

HCCA APs in OBSSs for which dot11PublicHCCATXOPNegotiationActivated is true or dot11ProtectedHCCATXOPNegotiationActivated is true synchronize their TSF timing so that the HCCA TXOP advertisement scheme does not suffer from time differences between the clocks of the overlapping APs.

In order to use HCCA TXOP advertisement, the AP maintains synchronization with its APs in OBSSs. HCCA APs that use HCCA TXOP advertisement shall use a DTIM interval with a duration of $2^n \times 100$ TU where n a non-negative integer less than or equal to 5.

NOTE—The DTIM interval of the form $2^n \times 100$ TU has been chosen to facilitate the verification that HCCA TXOP reservations do not overlap. The restriction that n be less than or equal to 5 has been chosen so that the range of the HCCA TXOP start time in the reservation (see 9.4.1.41) is compatible with the maximal DTIM interval length.

11.26.4.2 Timing offset

An HCCA AP with dot11PublicHCCATXOPNegotiationActivated true or dot11ProtectedHCCATXOPNegotiationActivated true shall update the timing offset value based on time stamps from the received Beacon frames from HCCA APs that have an entry in the dot11APCTable. The timing offset value is calculated using Equation (11-15).

$$T_{offset} = T_T - T_R \tag{11-15}$$

where

T_{offset} is the timing offset value
T_T is the value in the Timestamp field in the received Beacon frame from the overlapping HCCA AP
T_R is the Beacon frame reception time measured using the HCCA AP's TSF timer

The offset value is represented as 2s complement. The unit of the offset value is microseconds. The HCCA AP shall keep the T_{offset} value calculated from the latest Beacon frame received from each AP in an OBSS.

11.26.4.3 Clock drift adjustment

When dot11RobustAVStreamingImplemented is true and dot11PublicHCCATXOPNegotiationActivated is true, the HCCA AP shall examine the reception time of the Beacon frames from overlapping HCCA APs with which it maintains synchronization and adjust its TSF timer to compensate the relative timing error among overlapping HCCA APs caused by the clock drift. The HCCA AP adjusts its TSF so that its TSF counting frequency is aligned to the AP with the lowest TSF counting frequency.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The HCCA AP shall operate the following clock drift compensation procedure:

a) If the HCCA AP does not have a valid T_{offset} value obtained from the previous Beacon frame reception from a particular overlapping HCCA AP, it shall not operate the clock drift compensation for that AP.

b) When the HCCA AP receives a Beacon frame from one of the overlapping HCCA APs with which it maintains synchronization, the HCCA AP shall calculate the clock drift amount $T_{ClockDrift}$ by comparing the T_{offset} obtained previously for this overlapping HCCA AP and the T_{offset} obtained from the Beacon frame reception. See Equation (11-16).

$$T_{ClockDrift} = T_{offset,1} - T_{offset,0} \quad (11\text{-}16)$$

where

$T_{ClockDrift}$ is the clock drift amount represented as 2s complement, in microseconds
$T_{offset,1}$ is the T_{offset} obtained from the previous reception
$T_{offset,0}$ is the T_{offset} obtained from the current frame reception

c) The HCCA AP shall calculate the $T_{ClockDrift}$ value for all overlapping HCCA APs with which it maintains synchronization and select the largest $T_{ClockDrift}$ value. If the largest $T_{ClockDrift}$ is greater than zero, it shall suspend its TSF timer for the duration of the largest $T_{ClockDrift}$. The HCCA AP shall suspend its TSF timer frequently enough that the delay during a single beacon period does not exceed 0.08% of its beacon interval.

NOTE—This clock drift compensation procedure is not intended to maintain a strict synchronization. It aims to stop TBTT drifting away among overlapping HCCA APs to allow some jitter of TSF timer.

11.27 DMG beamformed link and BSS maintenance

11.27.1 Beamformed link maintenance

11.27.1.1 General

A pair of DMG STAs that have established a beamformed link can maintain this link. This subclause describes procedures that allow a pair of DMG STAs to maintain a beamformed link that was established between them.

A beamformed link is established as a result of the most recent success of the procedures specified in 10.41.2 if the STAs completed the SLS phase or as a result of the most recent success of the procedures specified in 10.41.6.4 if the STAs completed the BRP phase.

A DMG STA shall negotiate the value of dot11BeamLinkMaintenanceTime using the procedures specified in 10.41.6.2 or may leave it undefined as specified in 9.5.6.

If the dot11BeamLinkMaintenanceTime has been defined as described in 9.5.6, a DMG STA shall implement a beam link maintenance timer to control each beamformed link. The STA shall keep one beam link maintenance timer per beamformed link. After it is set, the beam link maintenance timer shall count down. The timer shall be stopped when it reaches the value zero. The beam link maintenance timer of a beamformed link shall be halted during the following periods of time:

— BTI and A-BFT of a beacon interval
— SPs and CBAPs in which the STA does not participate
— When any of the STAs involved in the beamformed link is in doze state

The beam link maintenance timer shall be set to dot11BeamLinkMaintenanceTime when the source DMG STA and destination DMG STA successfully complete the BRP if the beam refinement phase is performed

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

(10.38.3) or the source DMG STA and destination DMG STA successfully complete the SLS (10.41.2) if the beam refinement phase is skipped as defined in 10.38.3.

A DMG AP or PCP shall set the beam link maintenance timer to dot11BeamLinkMaintenanceTime when it receives a response from the non-AP and non-PCP DMG STA during the ATI or when it receives an SPR frame as a response to a Poll frame, if these frames are received using the beamformed link established with the non-AP and non-PCP DMG STA.

The non-AP and non-PCP DMG STA shall set the beam link maintenance timer to the dot11BeamLinkMaintenanceTime when it receives a request from the DMG AP or PCP during the ATI or when it receives a Poll or a Grant frame, if these frames are received using the beamformed link established with the DMG AP or PCP.

The initiator DMG STA shall set the beam link maintenance timer to the dot11BeamLinkMaintenanceTime when an immediate response or acknowledgment (Ack, BlockAck, DMG CTS, DMG DTS) has been received from the recipient DMG STA of the beamformed link.

The recipient DMG STA shall set the beam link maintenance timer to the dot11BeamLinkMaintenanceTime after the transmission of the immediate response or acknowledgment (Ack, BlockAck, DMG CTS, DMG DTS) has been completed to the initiator DMG STA of the beamformed link.

When a DMG STA with dot11DMGOCBActivated equal to true establishes a beamformed link with a peer STA, the STA shall generate an MLME-OCB-LINKSTATUS.indication with the BeamLinkStatus parameter set to ESTABLISHED or an MLME-OCB-DMGDISCOVERY.indication to inform the SME of the establishment of the beamformed link with the peer STA.

NOTE—When the beamformed link was established as a result of the discovery and the STA generated an MLME-OCB-DMGDISCOVERY.indication primitive as specified in 11.1.4.7, the STA might omit generation of an MLME-OCB-LINKSTATUS.indication.

To prevent expiration of the beam link maintenance timer when a DMG STA does not have MSDUs to send, the STA shall transmit QoS Null frames to maintain a beamformed link.

Following the expiration of the beamlink maintenance time (specified by the current value of dot11BeamLinkMaintenanceTime), the destination DMG STA of the SP shall configure its receive antenna to a quasi-omni antenna pattern for the remainder of the SP and during any SP following the expiration of the beamlink maintenance time.

Any time after dot11BeamLinkMaintenanceTime has elapsed, the source DMG STA of the SP may initiate an ISS to restore the beamformed link with the destination DMG STA of the SP following the rules defined in 10.41.2. The source DMG STA may initiate the ISS before expiration of dot11BeamLinkMaintenanceTime.

The responder DMG STA of the beamformed link in the CBAP shall configure its receive antenna to a quasi-omni antenna pattern following the expiration of dot11BeamLinkMaintenanceTime except when it is involved in a frame exchange sequence with another STA.

Any time after dot11BeamLinkMaintenanceTime has elapsed, the initiator DMG STA of the beamformed link in the CBAP may initiate an ISS to restore the beamformed link with the responder STA following the rules defined in 10.41.2. The initiator STA may initiate the ISS before expiration of dot11BeamLinkMaintenanceTime.

Upon expiration of dot11BeamLinkMaintenanceTime, a DMG STA for which dot11DMGOCBActivated is true shall generate an MLME-OCB-LINKSTATUS.indication primitive with BeamLinkStatus parameter set to EXPIRED to inform the SME of the expiration of the beam link maintenance timer with the peer STA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If a DMG STA detects degradation in the link quality between itself and another STA, the STA can use beam tracking or beam refinement to improve the link quality. The STA can request the AP or PCP to schedule an SP to perform BF with the other STA or use a CBAP to perform BF. The STA can use the A-BFT to perform BF if the other STA is its AP or PCP. A DMG AP or PCP can perform BF with a non-AP and non-PCP STA during a CBAP or by scheduling an SP between the AP or PCP and the non-AP and non-PCP STA through an Extended Schedule element transmitted in a DMG Beacon or Announce frame.

If the link quality between a DMG AP or PCP and a non-AP and non-PCP DMG STA degrades, but the STA can still receive DMG Beacon frames with the Next A-BFT field equal to 0, the STA should improve the link quality by performing RSS during the A-BFT period as described in 10.41.5.

A DMG STA may use the value of the parameter LAST_RSSI in the RXVECTOR of a received frame to decide to initiate beamforming with a peer STA if the value of the LAST_RSSI parameter is different from zero (10.3.2.3.3).

Figure 11-85 illustrates the operation of the beam link maintenance timer for an example involving STA-A and STA-B. In beacon interval *n*, STA-A and STA-B successfully perform beamforming and set up the beam link maintenance timer. In beacon interval *n*+1, the STAs have two SPs established between them. The beam link maintenance timer is halted and released according to the rules described above. Once the timer beam link maintenance timer expires, the STAs redo beamforming.

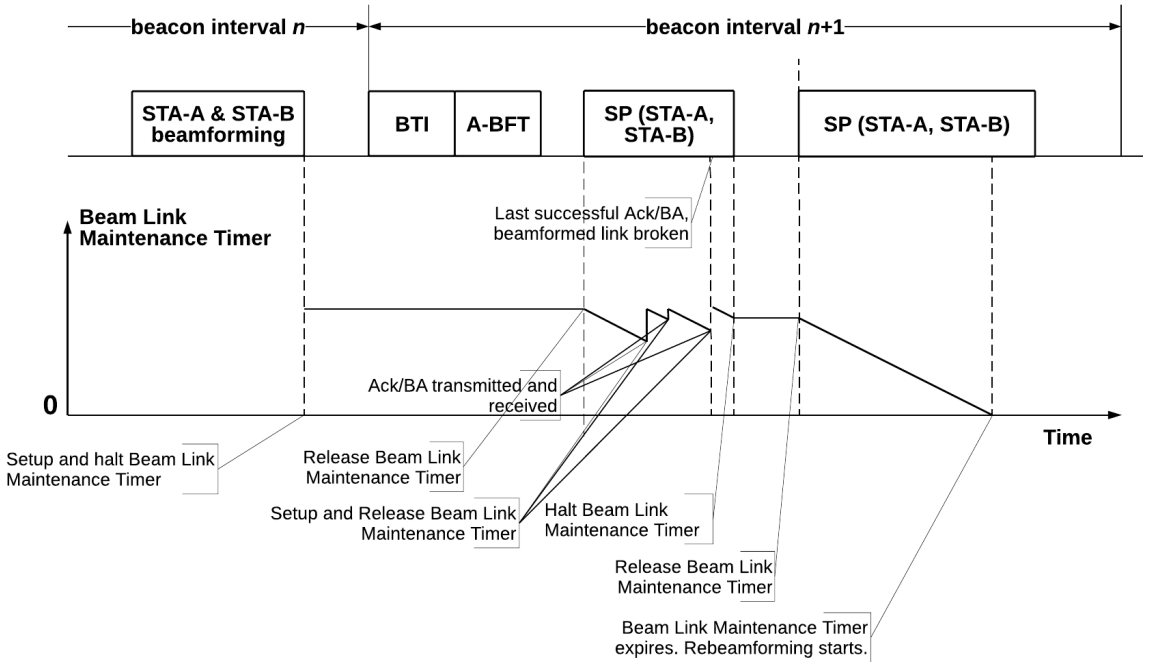

Figure 11-85—Example of beamformed link maintenance

11.27.1.2 EDMG partial SLS

An initiator and responder that are EDMG STAs are partial SLS ready if

— Either the initiator or the responder, or both the initiator and the responder, have more than one DMG antenna, and

— The initiator and responder have successfully exchanged an EDMG Partial Sector Level Sweep element (see 10.41.6.4.1 (General))

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

When the beam link maintenance timer expires on a link between an initiator and a responder that are partial SLS ready,

1) The responder shall configure its receive DMG antenna to a quasi-omni pattern and switch its receive DMG antennas at a rate of once per a time interval equal to MBIFS plus the number of sectors indicated in the Partial Number of Sectors field of the last EDMG Partial Sector Level Sweep element received from the initiator multiplied by (TXTIME(SSW frame)+SBIFS).
2) The initiator shall initiate an ISS with the number of sectors indicated in the Partial Number of Sectors field of the last EDMG Partial Sector Level Sweep element it sent to the responder. The initiator shall repeat this set of sectors for one plus the number indicated in the Partial Number of RX Antennas field in the last EDMG Partial Sector Level Sweep element received from the responder.
3) When the initiator finishes the ISS, it shall configure its receive antennas to a quasi-omni pattern and switch its receive DMG antennas at a rate of once per a time interval equal to MBIFS plus the number of sectors indicated in the Partial Number of Sectors field of the last EDMG Partial Sector Level Sweep element received from the responder multiplied by (TXTIME(SSW frame)+SBIFS).
4) If the responder received at least one SSW frame from the initiator during step 1, it shall wait for the time indicated in the Duration field of that frame and initiate an RSS with the number of sectors indicated in the Partial Number of Sectors field of the last EDMG Partial Sectors Level Sweep element it has sent to the initiator. The responder shall repeat the RSS to each DMG antenna of the initiator according to the number indicated in the Partial Number of RX Antennas field in the last EDMG Partial Sectors Level Sweep element received from the initiator.

If the time indicated in the Time to Switch to Full Sector Sweep field sent by the initiator to the responder in the last EDMG Partial Sectors Level Sweep element following the expiration of the dot11BeamLinkMaintenanceTime has passed and the initiator and responder have not completed a succsesfull SLS, the initiator and responder shall perform the following steps:

5) The responder shall configure its receive antenna to a quasi-omni pattern and switch its receive DMG antennas at a rate of once per a time interval equal to MBIFS plus the number of sectors indicated in the Total Number of Sectors field of the last EDMG Partial Sector Level Sweep element received from the initiator multiplied by (TXTIME(SSW frame)+SBIFS).
6) The initiator shall initiate an ISS with the number of sectors indicated in the Total Number of Sectors field of the last EDMG Partial Sector Level Sweep element sent to the responder. The initiator shall repeat the ISS for one plus the number indicated in the Total Number of RX Antennas field in the last EDMG Partial Sector Level Sweep element received from the responder.
7) When the initiator finishes the ISS, it shall configure its receive DMG antennas to a quasi-omni patterm and switch its receive DMG antennas at a rate of once per a time interval equal to MBIFS plus the number of sectors indicated in the Total Number of Sectors field of the last EDMG Partial Sector Level Sweep element received from the responder multiplied by (TXTIME(SSW frame)+SBIFS).
8) If the responder received at least one SSW frame from the initiator during step 5, it shall wait until the time indicated in the Duration field of that frame and initiate an RSS with the number of sectors indicated in the Partial Number of Sectors field of the last EDMG Partial Sector Level Sweep element it has sent to the initiator. The responder shall repeat this RSS for each DMG antenna of the initiator according to the number indicated in the Total Number of RX Antennas field in the last EDMG Partial Sector Level Sweep element received from the initiator.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the initiator and responder agreed to change roles according to the procedure described in 10.41.6.4.1 (General), the initiator and responder in step 1 through step 8 shall become, respectively, the responder and initiator of the EDMG Partial Sector Level Sweep element exchange.

If the procedure in step 1 through step 8 does not complete before the end of the allocation (SP or TXOP) in which the procedure started is reached, the initiator and responder shall resume the procedure at step 5 at the next available allocation.

11.27.2 PCP Handover

11.27.2.1 General

A STA is PCP handover capable if the PCP Handover field in the STA's DMG Capabilities element (9.4.2.126) is 1. The STA is PCP handover incapable otherwise.

The PCP handover process allows the information pertinent to the operation of the PBSS to be distributed to suitable PCP handover capable STA(s) and for a PCP handover capable STA to take over the PCP responsibilities from the PCP explicitly or implicitly.

The information pertinent to the operation of a PBSS includes STA information and pseudo-static scheduling information.

The STA information comprises the STA's AID, MAC address, and DMG Capabilities element. The PCP may relay the information to all STAs in the PBSS by using the Information Response frame.

The pseudo-static scheduling information comprises pseudo-static SP and CBAP allocations carried in the Extended Schedule element (9.4.2.130).

A PCP handover capable STA supports two types of PCP Handover, explicit and implicit. In explicit PCP handover, the PCP explicitly selects and schedules the transfer of PCP responsibilities to another PCP handover capable STA as described in 11.27.2.2. In implicit PCP handover the PCP distributes the Next PCP List element (9.4.2.139) in its DMG Beacon or Announce frames and maintains the content of the Next PCP List element to facilitate the implicit handover process described in 11.27.2.3. The PCP may determine the priority of next PCPs and update the next PCP list based on information contained within a STA's DMG Capabilities element.

If there is at least one PCP handover capable STA in the PBSS, the NextPCP List element contains an ordered list of one or more PCP handover capable STAs that can take over the role of the PCP during implicit handover. The ordering of STAs in the NextPCP List is specified in decreasing priority order and the criteria for updating the NextPCP List are implementation specific. The PCP shall increment the Token field of the NextPCP List by 1 every time the list is changed. If there are no PCP handover capable STAs in the PBSS, the length of the NextPCP List element is 0, and implicit PCP handover cannot be performed.

When a PCP handover capable STA takes over the PCP responsibilities of a PBSS, the pseudo-static scheduling information shall remain unchanged. Any outstanding request for resource allocation is lost and STAs that have outstanding requests for allocation may request the resource allocation again.

In explicit PCP handover, the PCP shall use the value of the PCP factor when selecting the candidate PCP (see 11.1.4.3.10).

Following a PCP handover, a non-PCP STA shall attempt to transmit a frame to the new PCP within dot11MaxLostBeacons beacon intervals. If the new PCP does not receive at least one frame from an associated non-PCP STA for dot11MaxLostBeacons beacon intervals following a PCP handover, it should disassociate the STA from the PBSS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

11.27.2.2 Explicit handover procedure

The PCP may transmit a Handover Request frame to a non-PCP STA that is handover capable. Upon receiving a Handover Request, a non-PCP STA becomes the candidate PCP. If the handover request is accepted, the candidate PCP shall transmit a Handover Response frame to the PCP with the Handover Result field set to 0. If the handover request is rejected, the candidate PCP shall transmit a Handover Response frame to the PCP with the Handover Result field set to 1, 2, or 3 and cease to be the candidate PCP.

A non-PCP STA that is handover capable may transmit a Handover Request frame to the PCP of the PBSS if the PCP is handover capable. Upon transmission of the Handover Request frame, the non-PCP STA becomes the candidate PCP. If the handover request is accepted, the PCP shall transmit a Handover Response frame to the candidate PCP with the Handover Result field set to 0. If the handover request is rejected, the PCP shall transmit a Handover Response frame to the candidate PCP with the Handover Result field set to 1, 2, or 3, and the candidate PCP shall cease to be a candidate PCP.

Following the transmission or reception of a successful Handover Response frame, a candidate PCP should request STA information and pseudo-static scheduling information from the PCP using an Information Request frame within the next dot11NbrOfChangeBeacons beacon intervals. The candidate PCP should also request SPs to perform beamforming and, if appropriate, establish a security association with other associated STAs prior to the completion of PCP handover.

Following the reception or transmission of a Handover Response frame, the PCP shall transmit a PCP Handover element within every DMG Beacon or Announce frame for each of the next dot11NbrOfChangeBeacons beacon intervals with the Old BSSID field set to the BSSID of the PBSS, the New PCP Address field set to the MAC address of the candidate PCP, and the Remaining BIs field set to the number of beacon intervals remaining until the candidate PCP takes over the role of PCP for the PBSS. The initial value of the Remaining BIs field shall be equal to the Handover Remaining BI field value last transmitted by the PCP in a Handover Request frame to the candidate PCP or equal to the Handover Remaining BI field value last received by the PCP in a Handover Request frame from the candidate PCP, whichever is later. A non-PCP STA receiving a DMG Beacon or Announce frame containing the PCP Handover element shall set the STA's local countdown counter to the value of the Remaining BIs field contained in the PCP Handover element. The STA shall then decrease the local countdown counter by one at each TBTT, and shall use the candidate PCP's address contained in the New PCP Address field within the PCP Handover element as the new beacon filter address once the STA's local countdown reaches zero. When the countdown timer equals zero, the candidate PCP shall assume the role of PCP.

11.27.2.3 Implicit handover procedure

Upon receiving the NextPCP List element, a PCP handover capable STA that finds its AID as the AID entry *i* in the NextPCP List element received from the PCP becomes the implicit candidate PCP *i*. Upon detecting a Token value contained in the NextPCP List element that is different from the value of the last Token received from the PCP, each implicit candidate PCP should request STA information and pseudo-static scheduling information from the PCP by transmitting an Information Request frame addressed to the PCP (11.28.1).

The implicit handover process is triggered at the implicit candidate PCP *i* when the implicit candidate PCP *i* fails to receive a DMG Beacon or Announce frames from the PCP for (*i* × dot11ImplicitHandoverLostBeacons) beacon intervals. When triggered, the implicit candidate PCP *i* shall send at least one DMG Beacon frame during each of the next dot11MaxLostBeacons BTIs if the following conditions are met:

— No DMG Beacon or Announce frames are received from the PCP.
— No DMG Beacon frame carrying a PCP Handover element with the Old BSSID field equal to the BSSID of the PBSS is received from an implicit candidate PCP with a smaller index on the NextPCP List.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Each DMG Beacon frame sent by the implicit candidate PCP *i* shall contain a PCP Handover element with the Old BSSID field set to the BSSID of the PBSS from which control is being taken, i.e., the previous PBSS, the New PCP Address field set to its MAC address, and the Remaining BIs field initially set to dot11MaxLostBeacons and decremented by 1 at each TBTT. A member non-PCP STA of the PBSS, after failing to receive a DMG Beacon or Announce frame for dot11MaxLostBeacons beacon intervals, should associate with the new PCP sending a DMG Beacon frame containing the PCP Handover element with Old BSSID field equal to the BSSID of the previous PBSS and the smallest Remaining BIs field value. The implicit candidate PCP that successfully transmits a DMG Beacon frame with the Remaining BIs field within the PCP Handover element equal to 0 completes the implicit handover by scheduling, if appropriate, pseudo-static SPs between its member STAs following the pseudo-static scheduling information it obtained from the previous PBSS.

To avoid disruptions to pseudo-static SPs due to implicit handover, the value of dot11ImplicitHandoverLostBeacons should be lower than dot11MaxLostBeacons.

11.28 DMG BSS peer and service discovery

11.28.1 Information Request and Response

A STA may request information about either a single STA in the BSS or about all of the STAs in the BSS by sending an Information Request frame (9.6.19.4). If the STA is requesting information about only a single STA in the BSS, it shall set the Subject Address field in the Information Request frame to the MAC address of that STA. If the STA is requesting information about all of the STAs in the Infrastructure BSS and PBSS, it shall set the Subject Address field in the Information Request frame to the broadcast address and shall transmit the Information Request frame to the AP and PCP.

A STA may transmit an Information Request frame with the Length field of the Request element set to 0 and with no Extended Request element present to another STA in the BSS to determine if the destination DMG STA is still present in the PBSS and is within range of the sending STA.

A STA may transmit an Information Request frame including its STA Capability element and other elements. A non-PCP and non-AP STA shall not include in the Information Request frame the capability information corresponding to another STA.

The STA may transmit an Information Response frame (9.6.19.4) either unsolicited or as a response to an Information Request frame. If a STA is providing information about a single STA in the BSS, it shall set the Subject Address field in the Information Response frame to the MAC address of that STA. If a STA is providing information about all of the STAs in the PBSS, it shall set the Subject Address field in the Information Response frame to the broadcast address.

A STA processes a received Information Request frame as follows:

— Each element that is listed in a Request element, Extended Request element, or Vendor Specific Request element and that is supported by the STA shall be included in the Information Response frame. An element that is listed in a Request element, Extended Request element, or Vendor Specific Request element and that is not supported by the STA shall not be included.

— If dot11RadioMeasurementActivated is true and the RCPI element was requested, an RCPI element containing the RCPI of the Probe Request frame shall be included. If no measurement result is available, the RCPI value shall be set to indicate “Measurement not available” (see Table 9-215).

— If dot11RadioMeasurementActivated is true and the RSNI element was requested, an RSNI element containing the RSNI of the Probe Request frame shall be included. If no measurement result is available, the RSNI value shall be set to indicate that a measurement is not available (see 9.4.2.39).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

A STA shall send an Information Response frame with no requested or provided elements in response to an Information Request frame that solicits information about a single target STA, as identified by the Subject Address field within the Information Request frame, if

— The target STA is not a member of the PBSS and the STA sending the Information Response frame is the PCP of the PBSS, or AP of the Infrastructure BSS and PBSS, or

— The STA sending the Information Response frame is a non-PCP and non-AP STA and is not the target STA.

In all other cases, the STA shall send the Information Response frame with the information requested by the requesting STA.

11.28.2 Peer Service Discovery

An AP or PCP may provide different types of information to a non-AP and non-PCP STA upon request. To query available services in a BSS, a non-AP and non-PCP STA shall send either an Information Request frame or a Probe Request frame to the AP or PCP (11.28.1). The Information Request and Information Response frames are robust Management frames, while the Probe Request and Probe Response frames are not.

Upon receiving the Information Request frame, the AP or PCP shall respond with an Information Response frame only if all of the following three criteria are true:

a) The SSID in the Information Request frame is the wildcard SSID or the specific SSID of the AP's or PCP's BSS.

b) The BSSID field in the Information Request frame is the wildcard BSSID or the BSSID of the AP or PCP's BSS.

c) The DA field in the Information Request frame is the MAC address of the AP or PCP.

The AP or PCP transmits the Information Response frame to the address of the non-AP and non-PCP STA that generated the Information Request.

11.29 Changing DMG BSS parameters

11.29.1 General

This subclause describes the methods used by the AP or PCP to change certain key characteristics of the BSS. It also describes a method for a non-AP and non-PCP STA to make a recommendation on those characteristics to the AP or PCP.

The AP or PCP delivers the DMG BSS Parameter Change element to STAs holding pseudo-static SPs and STAs in power save mode before a DMG BSS parameter change.

The AP or PCP shall initiate a DMG BSS parameter change by including a DMG BSS Parameter Change element (9.4.2.125) in its DMG Beacon or Announce frames. The AP or PCP places the DMG BSS Parameter Change element in every DMG Beacon or Announce frame after the DMG BSS Parameter Change element is first included in the frame, stopping in the DMG Beacon or Announce frame immediately after the DMG BSS parameter change takes effect.

11.29.2 Moving the TBTT

The AP or PCP may move the TBTT and hence move the entire beacon interval. Moving the beacon interval means that except for the beacon interval in which the change takes effect, the beacon interval duration is unchanged while the position of the TBTT is moved.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The TBTT shall not be moved by an amount that is larger than the value in the Beacon Interval field present in DMG Beacon and Announce frames in which the DMG BSS Parameter Change element is sent.

To move the TBTT to an intended new TBTT, the AP or PCP shall insert the DMG BSS Parameter Change element in DMG Beacon frames and/or Announce frames with the Move field set to 1 (9.4.2.125). The DMG Beacon frames and/or the Announce frames containing the DMG BSS Parameter Change element shall be sent at each TBTT dot11NbrOfChangeBeacons times before the TBTT is changed as indicated in the TBTT offset field.

At each transmission of the DMG BSS Parameter Change element, the TBTT Offset field shall be set to a value equal to the lower order 4 octets of the intended new TBTT.

The value of dot11NbrOfChangeBeacons shall be greater than dot11MaxLostBeacons.

NOTE—As defined in 11.1.2.1, the PCP transmits at least one DMG Beacon frame to each associated STA within a time interval that is not longer than dot11BeaconPeriod × dot11MaxLostBeacons TUs.

Announce frames shall be used to deliver the DMG BSS Parameter Change element to all STAs participating in pseudo-static SPs.

The Beacon Interval field of DMG Beacon frames and the Announce frames sent at the dot11NbrOfChangeBeacons+1 TBTT shall be set to the difference of the intended new TBTT and the TBTT where the DMG Beacon or Announce frames were sent.

STAs associated with an AP or PCP that moves the TBTT shall not transmit during the beacon interval that precedes a new TBTT if the transmission time ends at the TBTT or later, even if the SP or the CBAP were scheduled in the beacon interval.

At the intended new TBTT that is dot11NbrOfChangeBeacons+2 TBTTs after the DMG BSS Parameter Change element is first transmitted, the TSF timer is reset to 0 as defined in 11.1.3.3.

An AP or PCP member of an AP or PCP cluster that wishes to move its TBTT shall set the TBTT Offset field to an empty Beacon SP allocated by its S-AP or S-PCP as defined in 10.39.

Figure 11-86 illustrates the process in moving the TBTT position.

Figure 11-86—Moving the TBTT position

11.29.3 Changing beacon interval duration

The AP or PCP may change the duration of its beacon interval during the BSS operation.

To change its beacon interval, the AP or PCP shall insert the DMG BSS Parameter Change element into DMG Beacon frames and/or Announce frames with the Size field set to 1 and the BI Duration field set to the duration

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

of the beacon interval following this DMG BSS parameter change. The TBTT Offset field shall be set to the lower order 4 octets of the TBTT at dot11NbrOfChangeBeacons+1 TBTT position when this DMG BSS parameter change takes effect.

The DMG Beacon frames and/or the Announce frames shall be sent at each TBTT dot11NbrOfChangeBeacons times before the beacon interval is changed as indicated in the BI Duration field of the DMG BSS Parameter Change element.

At each transmission of the DMG BSS Parameter Change element the TBTT Offset field shall be set to a value equal to the lower order 4 octets of the intended TBTT.

The value of dot11NbrOfChangeBeacons shall be greater than dot11MaxLostBeacons.

Announce frames shall be used to deliver the DMG BSS Parameter Change element to all STAs participating in pseudo-static SPs.

The AP or PCP that shortens the beacon interval shall not schedule SP and CBAP allocations that use more time than allowed in the beacon interval indicated in the BI Duration field of the DMG BSS Parameter Change element.

The beacon interval shall be set to the value of the BI Duration field of the DMG BSS Parameter Change element at the dot11NbrOfChangeBeacons+1 TBTT. At this TBTT, the TSF timer is reset to 0 as defined in 11.1.3.3.

If the AP or PCP sets the Move and the Size fields to 1 in the same DMG BSS Parameter Change element, it shall set the TBTT Offset field and proceed as defined in 11.29.2. The beacon interval shall be set to the value of the BI Duration field of the DMG BSS Parameter Change element at the new TBTT as defined in 11.29.2.

Figure 11-87 illustrates the process in changing the beacon interval duration.

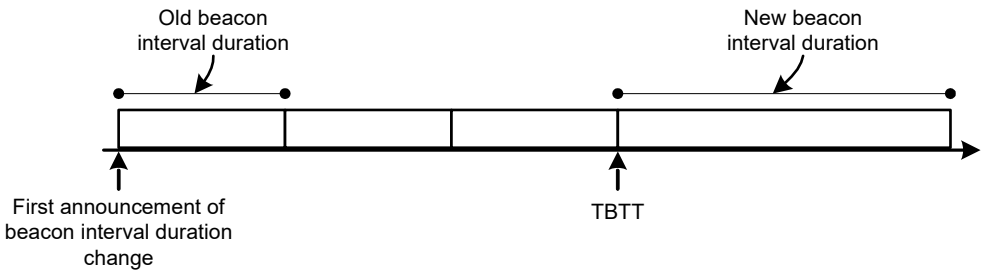

Figure 11-87—Changing beacon interval duration

11.29.4 Maintaining synchronization in an AP or PCP cluster

A S-AP or S-PCP shall update the Clustering Control field transmitted in the DMG Beacon frame if the DMG BSS parameter change modifies the allocation of the Beacon SPs (10.39). If the Clustering Control field is modified as a result of a DMG BSS parameter change, the S-AP or S-PCP shall transmit the updated Clustering Control field in every DMG Beacon frame in which the DMG BSS Parameter Change element is transmitted.

An AP or PCP member of an AP or PCP cluster receiving a S-AP or S-PCP DMG Beacon frame with a DMG BSS Parameter Change element indicating a change in the beacon interval duration or TBTT time shall immediately insert the appropriate DMG BSS Parameter Change element into its DMG Beacons if the S-AP or S-PCP's DMG BSS parameter change causes a modification in the allocation of the Beacon SPs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If an AP or PCP is required to change the beacon interval or/and TBTT to participate in an AP or PCP cluster or to change the beacon interval or/and TBTT as a result of its S-AP's or S-PCP's parameters change (see 10.39), it shall follow the procedures in 11.29.2 and 11.29.3.

11.29.5 Recommending DMG BSS parameters to the AP or PCP

A non-AP and non-PCP STA may make a recommendation for DMG BSS parameters to the AP or PCP by including a DMG BSS Parameter Change element in an Information Request or Information Response frame sent to the AP or PCP.

A non-AP and non-PCP STA may recommend a shift in TBTT by setting the Move subfield in the Change Type Bitmap field of the DMG BSS Parameter Change element to 1 and setting the TBTT Offset field to the value of the 4 least significant octets of the non-AP and non-PCP STA's TSF timer at the recommended first changed TBTT. The non-AP and non-PCP should select a value for the TBTT Offset field that gives the AP or PCP enough time to exercise the change. Similarly, a non-AP and non-PCP STA may recommend a beacon interval duration to the AP or PCP by setting the Size subfield in the Change Type Bitmap field of the DMG BSS Parameter Change element to 1 and setting the BI Duration field to the recommended beacon interval duration in TUs.

An AP or PCP that receives an Information Request frame or an unsolicited Information Response frame from a non-AP and non-PCP STA containing a DMG BSS Parameter Change element may use the information within the element to change the DMG BSS parameters. When receiving an Information Request frame that includes the DMG BSS Parameter Change element, AP or PCP responds with an Information Response frame as specified in 11.28.1. If the AP or PCP changes the BSS parameters in the transmitted Information Response frame, the AP or PCP shall include a DMG BSS Parameter Change element reflecting the BSS parameter changes and shall use the procedure defined in 11.29.2 and 11.29.3, as appropriate, to change the BSS parameters. If the AP or PCP decides not to change the BSS parameters, it shall not include a DMG BSS Parameter Change element in the transmitted Information Response frame.

11.30 Spatial sharing and interference mitigation for DMG STAs

11.30.1 General

This subclause describes mechanisms to enable spatial sharing and interference mitigation within a PBSS/ infrastructure BSS and in a uncoordinated OBSS environment. The mechanisms specified can operate on one or more channels.

Spatial sharing mechanisms allow SPs belonging to different STAs in the same spatial vicinity to be scheduled concurrently one or more channels, and for interference mitigation. Alternatively, the AP or PCP can use CBAPs to mitigate interference.

The SPSH and Interference Mitigation field in the DMG Capabilities element indicates whether a STA supports spatial sharing.

A STA that supports spatial sharing, as indicated in the SPSH and Interference Mitigation field equal to 1 in the STA's DMG Capabilities element, shall support the directional channel quality measurements described in 9.4.2.19.16 and 9.4.2.20.15.

An AP or PCP may use the beamforming training information between any pair of STAs within the BSS obtained through the SSW Report element (9.4.2.221) to achieve spatial sharing and interference mitigation. The AP or PCP can transmit an Information Request frame (9.6.19.4) addressed to a STA for a response with an SSW Report element (9.4.2.221) contained in an Information Response frame (9.6.19.5). A non-AP and non-PCP STA can also send an unsolicited Information Response frame with an SSW Report element after the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

STA has completed the beamforming procedure with at least another STA. The SSW Report element may be used to facilitate the selection of candidates for spatial sharing as described in W.1.

11.30.2 Spatial sharing and interference assessment

The AP or PCP should request STAs to perform and report spectrum and radio resource measurements described in 11.10 to assess the possibility to perform spatial sharing and for interference mitigation.

The AP or PCP should use the directional channel quality described in 9.4.2.19.16 and 9.4.2.20.15 to assess the possibility for spatial sharing of SPs over one or more channels.

An SP to be assessed for spatial sharing with other scheduled (existing) SPs or considered to be reallocated in the beacon interval is hereby termed as a candidate SP. There might be multiple candidate and existing SPs at one time, and an SP may simultaneously assume the role of candidate and existing SP depending upon the context it is used for spatial sharing and interference assessment.

STAs that participate in an SP and that support spatial sharing should perform beamforming training with each other before engaging in any other communication or performing any measurements described in this subclause.

For the purpose of spatial sharing with one or more existing SPs allocated on the same channel, the AP or PCP should request the source DMG STA and the destination DMG STA involved in a candidate SP to perform measurements only after the STAs have beamforming trained with each other. For the purpose of spatial sharing with one or more existing SPs allocated in different channels, the EDMG AP or EDMG PCP should request each source DMG STA and each destination DMG STA involved in each candidate SP to perform measurements only after the STAs have beamforming trained with each other. The AP or PCP can infer that the STAs in a candidate SP have a beamformed link with each other if the Beamforming Training field within the DMG TSPEC used to set up the candidate SP was set to 1 and at least one beacon interval has elapsed since the candidate SP was first scheduled.

If the AP or PCP transmits a Directional Channel Quality request to a STA involved in a candidate SP to assess the possibility for spatial sharing with one or more existing SPs, it shall set the Target STA to the corresponding peer STA’s MAC address involved in the candidate SP and shall set the Measurement Method field to indicate ANIPI. Additionally, the AP or PCP may include a Measurement Configuration subelement in the Directional Channel Quality request where the Measurement Channel Bitmap subfield indicates one or more 2.16 GHz channels for which the measurement request applies; in this case, it may set the Channel Measurement Report Method subfield to 0 to indicate the results of measurements over all the requested 2.16 GHz channels during each measurement time block are reported per 2.16 GHz channel or may set this subfield to 1 to indicate the averaged results of concurrent measurements over all the requested 2.16 GHz channels during each measurement time block are reported, and may set the Antenna Measurement Report Method subfield to 0 to indicate the results of concurrent measurements over each requested 2.16 GHz channel using multiple RX DMG antennas during a measurement time block are reported per DMG antenna or may set this subfield to 1 to indicate the averaged results of concurrent measurements over each requested 2.16 GHz channel using multiple RX DMG antennas during a measurement time block are reported, and may set the RX Antenna Configuration Type subfield to 0 to indicate the RX antenna configuration for SISO communication is requested to be used for measurements or may set this subfield to 1 to indicate the RX antenna configuration for SU-MIMO communication is requested to be used for measurements. Together with the Measurement Configuration subelement, the AP or PCP may also include an Extended Measurement Configuration subelement in the Directional Channel Quality request, where measurement timing information for the first requested channel is indicated in the Measurement Request field and measurement timing information for the remaining requested channels is indicated in the Extended Measurement Configuration subelement.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the candidate SP has already been allocated channel time, the AP or PCP should additionally transmit a Directional Channel Quality request to the STAs involved in each of the one or more existing SPs to assess the possibility for spatial sharing with the candidate SP. In the Directional Channel Quality request, the AP or PCP shall set the Target STA to the corresponding peer STA involved in the existing SP and shall set the Measurement Method field to indicate ANIPI. Additionally, the PCP or AP may include a Measurement Configuration subelement in the Directional Channel Quality request where the Measurement Channel Bitmap subfield indicates one or more 2.16 GHz channels for which the measurement request applies; in this case, it may set the Channel Measurement Report Method subfield to 0 to indicate the results of measurements over all the requested 2.16 GHz channels during each measurement time block are reported per 2.16 GHz channel or may set this subfield to 1 to indicate the averaged results of concurrent measurements over all the requested 2.16 GHz channels during each measurement time block are reported, and may set the Antenna Measurement Report Method subfield to 0 to indicate the results of concurrent measurements over each requested 2.16 GHz channel using multiple RX DMG antennas during a measurement time block are reported per DMG antenna or may set this subfield to 1 to indicate the averaged results of concurrent measurements over each requested 2.16 GHz channel using multiple RX DMG antennas during a measurement time block are reported, and may set the RX Antenna Configuration Type subfield to 0 to indicate the RX antenna configuration for SISO communication is requested to be used for measurements or may set this subfield to 1 to indicate the RX antenna configuration for SU-MIMO communication is requested to be used for measurements. Together with the Measurement Configuration subelement, the AP or PCP may also include an Extended Measurement Configuration subelement in the Directional Channel Quality request, where measurement timing information for the first requested channel is indicated in the Measurement Request field and measurement timing information for the remaining requested channels is indicated in the Extended Measurement Configuration subelement.

NOTE—When the AP or PCP transmits a Directional Channel Quality request to a STA of an existing SP, it intends to assess the channel quality during transmission by STAs belonging to the candidate SP. Similarly, when the AP or PCP transmits a Directional Channel Quality request to a STA of a candidate SP, it intends to assess the channel quality during transmission by STAs belonging to the existing SP.

If a recipient STA that receives a Directional Channel Quality request frame is already beamformed trained with the target STA specified by the AID field within the frame, then the recipient STA shall carry out the measurement employing the same receive antenna configuration as is used by the recipient STA when receiving frames from the target STA using a SISO antenna setting or shall carry out the measurements concurrently employing the same receive antenna configuration as is used by the recipient STA when receiving frames from the target STA using an SU-MIMO antenna setting. If the AID field is the broadcast AID or an unknown AID, then the recipient STA shall perform the measurements using a quasi-omni antenna pattern.

Figure 11-88 illustrates an example of spatial sharing assessment between two SPs. In this example, SP1 is the existing SP and SP2 is the candidate SP. The AP or PCP transmits a Directional Channel Quality request to STAs C and D to measure over SP1's channel allocation, and transmits a Directional Channel Quality request to STAs A and B to measure over SP2's channel allocation. The relation of the Measurement Start Time and Measurement Duration fields in the Directional Channel Quality request message is shown in Figure 11-88 , while the field Number of Time Blocks is the ratio (Measurement Duration/Measurement Unit).

If a non-AP and non-PCP STA receives a Directional Channel Quality request from its AP or PCP, it should perform the measurements as indicated in the request and shall report back to the AP or PCP using the Directional Channel Quality report. The report shall be formatted and transmitted as per specified in the Directional Channel Quality request. The non-AP and non-PCP STA shall set the Report Mode field (9.4.2.20) in the report frame to indicate whether it performed the measurement as requested by the AP or PCP.

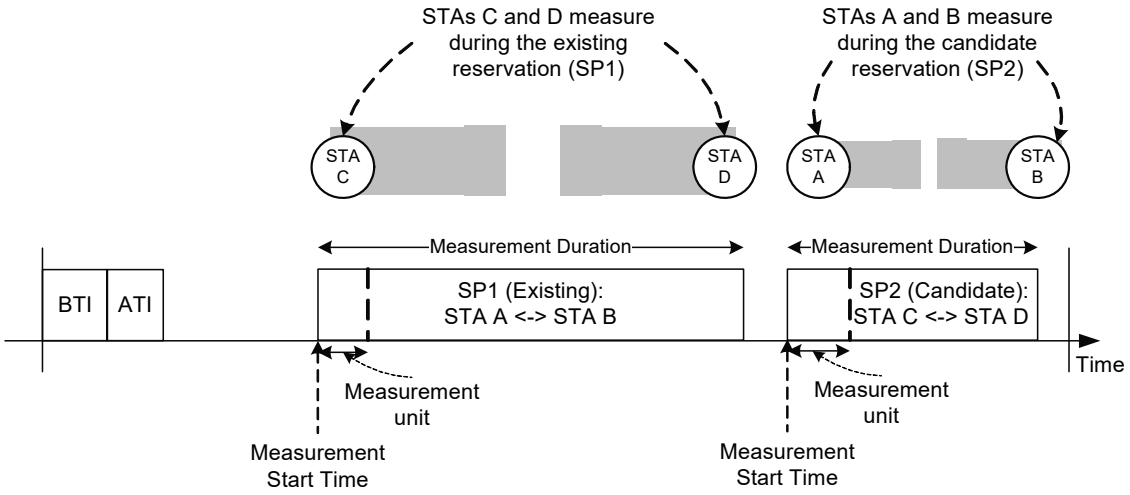

Figure 11-88—Example of spatial sharing assessment

11.30.3 Achieving spatial sharing and interference mitigation

An AP or PCP can estimate the channel quality across STAs participating in the BSS and implement spatial sharing and interference mitigation based on the results of the measurements performed by the STAs associated with the AP or PCP.

An AP or PCP should schedule a candidate SP that overlaps with an existing SP in its beacon interval only after it receives a Directional Channel Quality report from the STAs involved in the candidate SP. When an EDMG AP or EDMG PCP schedules a candidate SP that overlaps with an existing SP in its beacon interval, it may also recommend whether SISO transmission or SU-MIMO transmission is applied in the candidate SP by using the Recommended Transmission Scheme subfield in the EDMG Extended Schedule element.

If a candidate SP is already scheduled in the beacon interval, the AP or PCP should schedule this candidate SP time-overlapping with an existing SP in its beacon interval only after it receives a Directional Channel Quality report from the STAs involved in the existing SP. When an EDMG AP or EDMG PCP schedules this candidate SP time overlapping with an existing SP in its beacon interval, it may also recommend whether SISO transmission or SU-MIMO transmission is applied in this candidate SP by using the Recommended Transmission Scheme subfield in the EDMG Extended Schedule element.

The AP or PCP should schedule a candidate SP during a period of time in the beacon interval where the PBSS/infrastructure BSS performance is expected to be maximized. The determination of performance maximization should be based on measurement reports received by the AP or PCP, but is implementation dependent and beyond the scope of this standard.

The decision process at the AP or PCP to perform spatial sharing of a candidate and an existing SP is implementation dependent and beyond the scope of this standard.

The candidate SP is referred to as a *time-overlapped SP* following the allocation by the AP or PCP of a candidate SP overlapping in time with an existing SP.

Figure 11-89 illustrates an example of the resulting SP schedule in the beacon interval for the spatial sharing between the two SPs shown in Figure 11-88 .

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

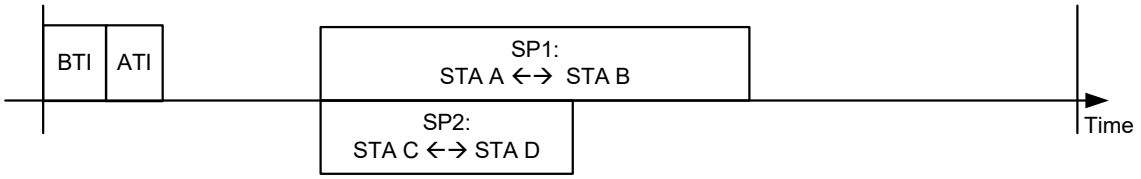

Figure 11-89—Example of spatial sharing between SP1 and SP2

The AP or PCP should periodically transmit a Directional Channel Quality request to each spatial sharing capable STA involved in a time-overlapped and existing SP scheduled under spatial sharing. In the Directional Channel Quality request that the AP or PCP transmits to each STA, the AP or PCP shall set the Target STA to the peer STA involved in the same SP and shall set the Measurement Method field to indicate RSNI.

If a spatial sharing capable non-AP and non-PCP STA receives a Directional Channel Quality request from its AP or PCP, it should perform the measurements as indicated in the request and shall report the results back to the AP or PCP using the Directional Channel Quality report. The report shall be formatted and transmitted as per specified in the corresponding Directional Channel Quality request.

The AP or PCP should stop the spatial sharing of two or more SPs if it determines that the link quality of any of the links involved in the spatial sharing has dropped below acceptable levels. This determination should be based on Directional Channel Quality reports received by the AP or PCP, but is implementation dependent and beyond the scope of this standard.

The STA may include the Traffic Scheduling Constraint Set field with the ADDTS Request frame sent to the AP or PCP for the purpose of interference mitigation. The AP or PCP should consider the information in the Traffic Scheduling Constraint Set field specified by a STA in its SP schedule.

Specific algorithms to realize spatial sharing and interference mitigation among SPs between different STAs is implementation dependent and beyond the scope of this standard.

11.30.4 PBSS and infrastructure BSS stability in OBSS scenarios

Except when performing FST (11.31), the AP or PCP limits the frequency with which it changes the operating PBSS/infrastructure BSS channel to alleviate the instability and ripple effect that might result from frequent channel changes in OBSS scenarios. Upon a channel switch, the AP or PCP of a PBSS/infrastructure BSS shall select a random number, N, uniformly distributed between [0, SwitchInterval-1] and shall not attempt a new channel switch until N beacon intervals have elapsed since the preceding channel switch. The initial value of SwitchInterval is aMinSwitchInterval and it is doubled upon every new channel switch up to a maximum value of aMaxSwitchInterval. The AP or PCP resets SwitchInterval to aMinSwitchInterval if it remains on the same operating channel for a minimum of aMaxSwitchInterval consecutive beacon intervals.

NOTE—The AP or PCP can keep the SP schedule stable across beacon intervals and minimize schedule changes. This is to allow for STAs to associate with the PBSS/infrastructure BSS or add or modify their SP reservations. Stability in the allocation schedule in a beacon interval allows a PBSS/infrastructure BSS to assess the interference pattern produced by OBSSs and adapt to the environment by scheduling SPs over periods of time in the beacon interval when less interference is expected.

11.30.5 Directional transmit activity report

DMG STAs for which dot11DMGSTATxActivityReportImplemented is true are capable of transmitting DMG STA Directional Transmit Activity Report frames which, for a given receiving STA (or group of receiving STAs as defined below) and a given 2.16 GHz channel, include information that helps the receiving STAs unintentionally affected by the radiation pattern (more precisely, STAs that receive energy

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

when the transmitting STA uses the given antenna pattern to communicate with its intended targets) to mitigate the interference caused by the transmitting STA, as well as the interference these receiving STAs cause to the transmitting STA.

A STA with both dot11DMGSTATxActivityReportImplemented and dot11DMGSTATxActivityReportActivated equal to true regularly transmits DMG STA Directional Transmit Activity Report frames (activity report frames, for short) as follows.

For each receiver (or group of receivers always transmitted data through a common transmit antenna pattern and transmit power) and each 2.16 GHz channel that the transmitting STA is using to communicate with the receiver(s), the STA monitors its transmit activity in terms of number of active time units, contiguous or noncontiguous, during a sliding window comprising a given number of time units. An active time unit is a period during which the STA has been in transmit mode for a percentage of the time unit greater than or equal to aDMGActiveThresholdPercentage, excluding any time spent towards transmitting a DMG Beacon frame or a PPDU that contains only activity report frames, using the common antenna pattern and the transmit power, and using the 2.16 GHz channels. The time unit duration, in microseconds, is dot11DMGSTATxActivityReportTimeUnit.

As long as the STA has observed at least dot11DMGSTATxActivityReportMinActiveTimeUnits active time units over the last dot11DMGSTATxActivityReportActiveMonitoringTime time units, it shall transmit a PPDU containing one activity report MMPDU, using the common antenna pattern, and on each of the 2.16 GHz channels used for data transmission, at least once during every dot11DMGSTATxActivityReportInterval microseconds, provided that the STA has a transmit opportunity longer than SIFS plus the duration of a PPDU that only includes one activity report frame. The interval between the start of transmission of consecutive Directional Transmit Activity Report frames shall not exceed aDMGSTATxActivityReportingtLimit. If the STA does not have the transmit opportunity to transmit the activity report frame during this time, it shall transmit the frame at the first opportunity.

NOTE 1—For example, the following settings require a capable DMG STA to transmit a DMG STA Directional Transmit Activity Report frame at least once during every second, as long as the STA has had at least 10 active seconds of transmission using a given antenna pattern over the last 60 seconds: dot11DMGSTATxActivityReportActivated = true, dot11DMGSTATxActivityReportTimeUnit = 1000000, dot11DMGSTATxActivityReportMinActiveTimeUnits = 10, dot11DMGSTATxActivityReportActiveMonitoringTime = 60, and dot11DMGSTATxActivityReportInterval = 1000000.

All transmitted activity report frames shall include the Country and DMG STA Directional Transmit Activity Report elements. The DMG STA Directional Transmit Activity Report element shall include the Directional Transmit Activity and Transceiver Parameters subelements.

The PPDUs containing an activity report frame should use the average effective TRP that the transmitting STA expects to apply when it communicates with other STAs using the common antenna pattern and occupying channels that are the same as, or include the channels used for the data transfer.

NOTE 2—For example, when the STA is communicating over a 4.32 GHz channel, it transmits the PPDUs that contain a transmit activity report frame at about half the power on each of the two 2.16 GHz channels in the 4.32 GHz channel.

A DMG STA that has the EDMG Supported subfield equal to 1 in the transmitted DMG Parameters field shall include DMG TRN-R subfields within its TRN field of the PPDU containing an activity report frame to enable receive training. Specifically, the STA transmitting such PPDU shall set the TRN-LEN parameter of the TXVECTOR of the PPDU to a value not less than 2 and shall set the PPDU_TYPE parameter of the TXVECTOR to TRN-R. The PPDU_TYPE parameter of the TXVECTOR of such PPDU shall not be set to TRN-T.

A STA may transmit individually addressed activity report frames to a target STA. When transmitting the activity report frame to a target STA in the same BSS, and when management frame protection is negotiated,

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the transmitting STA shall use individually addressed Protected Dual of Public Action frames instead of Public Action frames.

11.31 Multi-band operation

11.31.1 General

A device is multi-band capable if the value of dot11MultibandImplemented is true. A multi-band capable device is said to be a member of a BSS when one or more of the STAs in the device is a member of the BSS. A STA that is part of a multi-band capable device advertises the capability by including the Multi-band element in Beacon, DMG Beacon, (Re)Association Request, (Re)Association Response, Information Request, Information Response, Probe Request, Probe Response, Announce, FST Setup Request, FST Setup Response, TDLS Discovery Request, TDLS Discovery Response, TDLS Setup Request, and TDLS Setup Response frames.

Except for the FST Setup Request and FST Setup Response frames, which shall not include more than one Multi-band element, a STA may include more than one Multi-band element in any one of these frames if it is part of a device that supports more than two bands or channels. If an AP or PCP includes one or more Multi-band elements within a (Re)Association Response frame with Status Code equal to DENIED_WITH_SUGGESTED_BAND_AND_CHANNEL or a Probe Response frame, the order in which these elements appear in the frame indicate the order, in terms of frequency band and channel number, that the device that includes the STA addressed by the frame should attempt join the BSS following the rules applicable to the respective frequency band and channel (see 11.1). For each Multi-band element contained in the frame starting from the first one and proceeding in increasing order, the STA should attempt to join the BSS using the BSSID indicated by the BSSID field, frequency band indicated by the Band ID field and channel number indicated by the Channel Number field provided the Beacon Interval and the Channel Number fields in the Multi-band element are both nonzero.

NOTE—The first Multi-band element in the frame can refer to the current operating frequency band and channel.

A multi-band capable device shall set the Band ID and Operating Class fields within a Multi-band element to specify a frequency band it supports. If the multi-band capable device is or intends to operate in the band indicated within the Multi-band element, it shall set the Channel Number field to indicate the channel of operation within that band. If the multi-band capable device is a member of a BSS both on the channel indicated in the Channel Number field within the Multi-band element and also in the channel on which this element is transmitted, then the multi-band capable device shall set the TSF Offset field within a Multi-band element to the difference between the TSF of the BSS of which the STA is member on the channel indicated in the Channel Number field of this element and the TSF of the BSS corresponding to the BSSID indicated in the Address 3 field of the MPDU in which this element is transmitted. In all other cases, the TSF Offset field shall be set to 0.

In each band/channel, a multi-band capable device may use the same or different MAC addresses. When the STA MAC Address Present field is equal to 1 in a Multi-band element, the STA MAC Address field in the Multi-band element specifies the MAC address that the STA uses in the band and channel that are indicated in the Multi-band element. If the STA MAC Address Present field is 0, the MAC address that the STA uses in the frequency band and channel that are indicated in the Multi-band element is the same as the address the STA uses in the current operating band and channel.

The multi-band discovery assistance request is managed by the FST setup protocol and is used in conjunction with a session transfer. State transition of the discovery assistance request is described in 11.31.3 (FST setup protocol) and details of the multi-band discovery assistance procedure are described in 11.31.7 (Multi-band discovery assistance procedure). A STA may include a DMG Discovery Assistance element in an FST Setup Request frame only if the recipient STA sets the Discovery Assistance Enabled

subfield in the recipient STA's Multi-band element to 1. When a DMG Discovery Assistance element is present in the frame, it indicates a request for a discovery assistance to a recipient STA. A STA that supports the discovery assistance procedure and that receives a discovery assistance request shall include the DMG Discovery Assistance element in the FST Setup Response frame transmitted in response to a received FST Setup Response frame containing the multi-band discovery assistance request. If the Discovery Assistance Type subfield in a received DMG Discovery Assistance element is 1, the recipient STA shall include also an Extended Schedule element in the FST Setup Response frame and may include a TDD Slot Structure and TDD Slot Schedule elements.

11.31.2 General FST rules

The FST session (see 4.9.4) transition is managed by the FST session setup protocol. A multi-band capable device participates as an initiator or as a responder in the FST session setup. Depending on the STA's behavior during the FST session setup, the FST session can be operational in one band, or may be transferred to another band or channel in the same band, or can be operational in multiple bands and/or channels simultaneously and in this case MSDUs can be transmitted in different bands and/or channels any time an MSDU arrives at the MAC SAP. If a multi-band capable device is operational in more than one band/channel simultaneously, the STA may use the FST session setup protocol to change the operation to a single channel.

An FST session between an initiator and a responder is identified by a fast session transfer session identifier. The value of the fast session transfer session identifier is allocated by the initiator of an FST session and shall remain unchanged whether the FST session is operational in one band or more than one band simultaneously. The value of the fast session transfer session identifier shall be unique for an initiator and responder pair, and there shall be no more than one FST session between an initiator and responder pair. An initiator or responder may change the fast session transfer session identifier of its existing FST session by tearing down the existing FST session (11.31.4) and setting up a new one with a different fast session transfer session identifier value. The fast session transfer session identifier is signaled in the FSTS ID field. See 9.4.2.144, 9.6.20.4, 9.6.20.5, and 9.6.20.6.

The FST session addressing mode is transparent if both initiator and responder of the FST session use the same MAC address in the frequency bands/channels involved in the FST. The FST session addressing mode is nontransparent if either the initiator or responder use different MAC addresses in the different frequency bands/channels involved in the FST session. When transparent FST is used, the STA shall present a single MAC SAP to higher layers for all frequency bands/channels in which it uses that MAC address.

When transparent fast session transfer is used, use of Authentication is unnecessary, and use of Association is disallowed, between the initiator and the responder.

An FST is allowed if the FST Setup Request and FST Setup Response frames are permitted to be transmitted as indicated in 11.3.3.

A multi-band capable device should deliver all fragments, if any, of an MSDU of an FST session before it transfers the FST session.

A multi-band capable device shall include in any transmitted FST Setup Request frame and in any transmitted FST Setup Response frame, all the elements that are applicable to the band, PHY and channel number indicated within its most recently transmitted Multi-band element that was transmitted on the same band and channel number on which it is transmitting the FST Setup Request or FST Setup Response frames. If a Multi-band element is present in the transmitted FST Setup Request or FST Setup Response frames, the Multi-band element is considered as the most recently transmitted Multi-band element.

If a Session Transition element and a Multi-band element are present in the same frame and the values of the Operating Class and Channel Number fields within the Multi-band element are both nonzero, the Band ID field

related to the new band within the Session Transition element shall be the same as the Band ID field within the Multi-band element.

11.31.3 FST setup protocol

11.31.3.1 General

A STA supports the FST protocol if the FST Not Supported subfield within the STA's Multi-band element is 0. A STA should not transmit an FST Setup Request frame to a peer STA that does not support the FST protocol. A STA that does not support the FST protocol shall discard a received FST Setup Request frame.

The FST setup protocol comprises four states and rules for how to move from one state to the next. The states are Initial, Setup Completed, Transition Done, and Transition Confirmed. In the Initial state, the FST session is operational in one or both bands/channels. In the Setup Completed state, both initiator and responder are ready to change their currently operating band(s)/channel(s). An FST session can be fully or partially transferred to another band/channel. The Transition Done state enables both initiator and responder to operate in the other band/channel if the LLT field was zero. Both initiator and responder have to successfully communicate in the new band/channel to reach the Transition Confirmed state. The state transition diagram of the FST setup protocol is shown in Figure 11-91 .

Figure 11-90 depicts the procedure of the FST setup protocol that drives the state machine shown in Figure 11-91 . The figure is an example of only the basic procedure and is not meant to be exhaustive of all possible uses of the protocol. In the figure, MLME 1 and MLME 2 represent any two MLMEs of a multi-band capable device according to the reference model described in 4.9.4. The FST Setup Request and FST Setup Response frame exchange is repeated as necessary until both the FST initiator and FST responder successfully move to the Setup Completed state, as described below. Figure 11-90 illustrates this behavior.

To establish an FST session in the Initial state and transfer it to the Setup Completed state of the FST setup protocol (Figure 11-91), an initiator and responder shall exchange FST Setup Request and FST Setup Response frames. An FST session exists in Setup Completed state, Transition Done state, or Transition Confirmed state. In the Initial and in the Setup Completed states, the old band/channel represents the frequency band/channel from which the FST session is to be transferred, and the new band/channel represents the frequency band/channel to which the FST session is to be transferred. In the Transition Done state, the new band/channel represents the frequency band/channel on which the FST Ack Request and FST Ack Response frames, if any, are transmitted, and the old band/channel represents the frequency band/channel from which the FST session is being transferred.

The responder shall set the Status Code field to SUCCESS if it accepts the FST Setup Request, shall set the status code to REJECTED_WITH_SUGGESTED_CHANGES (see 9.4.1.9) to indicate that one or more parameters of the FST Setup Request frame are invalid and shall suggest alternative parameters, shall set the status code to PENDING_ADMITTING_FST_SESSION or PENDING_GAP_IN_BA_WINDOW to indicate that an FST setup request is pending, and shall set the Status Code field to REQUEST_DECLINED to reject an FST Setup Request frame.

A responder that is also an enabling STA (see 11.11) may set the status code to REJECT_DSE_BAND to indicate that the FST Setup Request frame is rejected because it was initiated by a dependent STA (see 11.11) that is requesting transition to a frequency band subject to DSE procedures. In this case, if the responder is the enabling STA for the dependent STA, the responder may include a TIE in the FST Setup Response frame to indicate the period in TUs before which it initiates an FST Setup with the dependent STA. The Timeout Interval Type field within the TIE shall be set to 4. The responder can use the parameters in the FST Setup Request frame received from the dependent STA to initiate an FST Setup with the initiator.

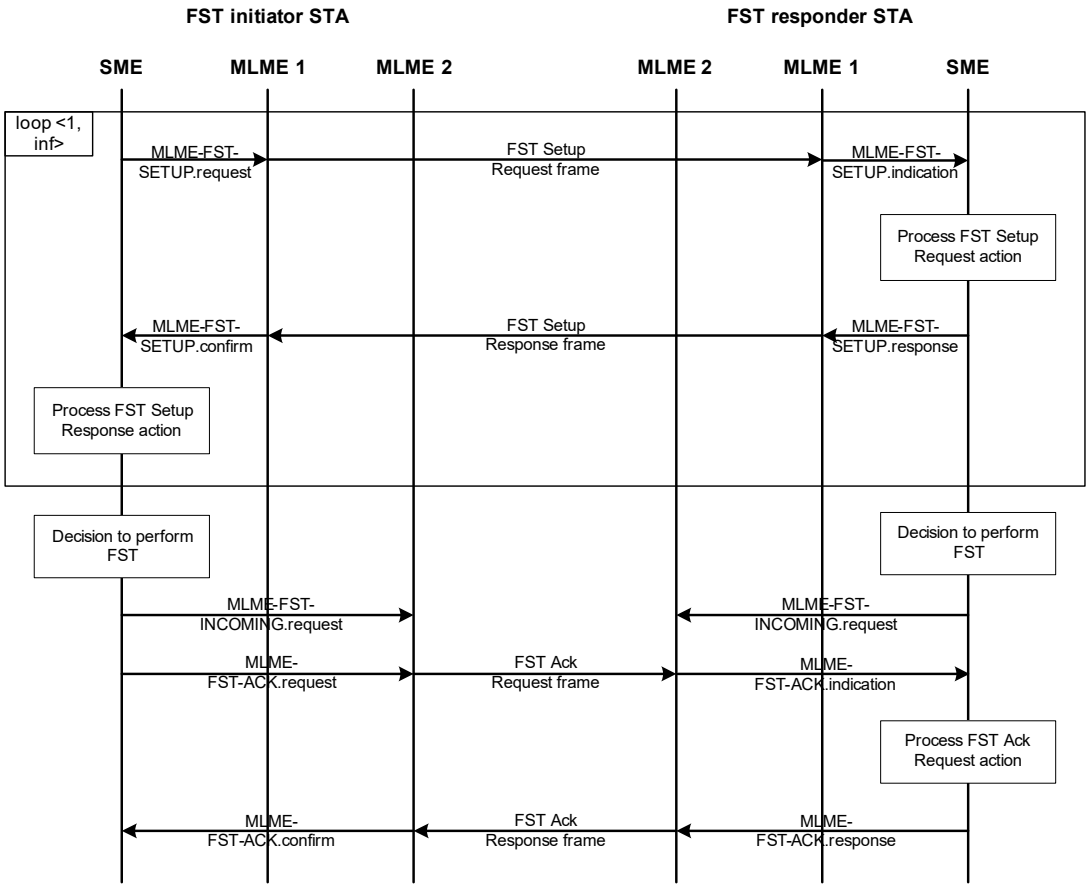

Figure 11-90—Procedure of the FST setup protocol

A responder that is also a dependent STA and not enabled shall reject all received FST Setup Request frames for transitioning to a frequency band subject to DSE procedures, except if the transmitter of the FST Setup Request frame is the enabling STA of the dependent STA.

11.31.3.2 Transitioning between states

A state transition within the FST setup protocol is controlled by the State Transition Timer (STT). Each STA maintains an STT for each FST session. A STA shall move to the Initial state when the STT moves from 1 to 0 (other than set to 0) or upon reception or transmission of an FST Teardown frame.

The initiator shall set the STT to the value of the FSTSessionTimeout field at successful transmission of an FST Setup Request frame and at each Ack frame sent in response to an FST Setup Response frame with the Status Code field equal to PENDING_ADMITTING_FST_SESSION or PENDING_GAP_IN_BA_WINDOW. The initiator shall set the STT to 0 at the transmission of an Ack frame sent in response to an FST Setup Response frame with the Status Code field equal to SUCCESS.

The responder shall set the STT to the value of the FSTSessionTimeout field at successful transmission of an FST Setup Response frame. The responder shall set the STT to 0 at each transmission of an Ack frame sent in response to an FST Setup Request. The responder should send an FST Setup Response frame no later than FSTSessionTimeout after the transmission of an Ack frame sent in response to an FST Setup Request frame or successful transmission of an FST Setup Response frame with the status code field equal to

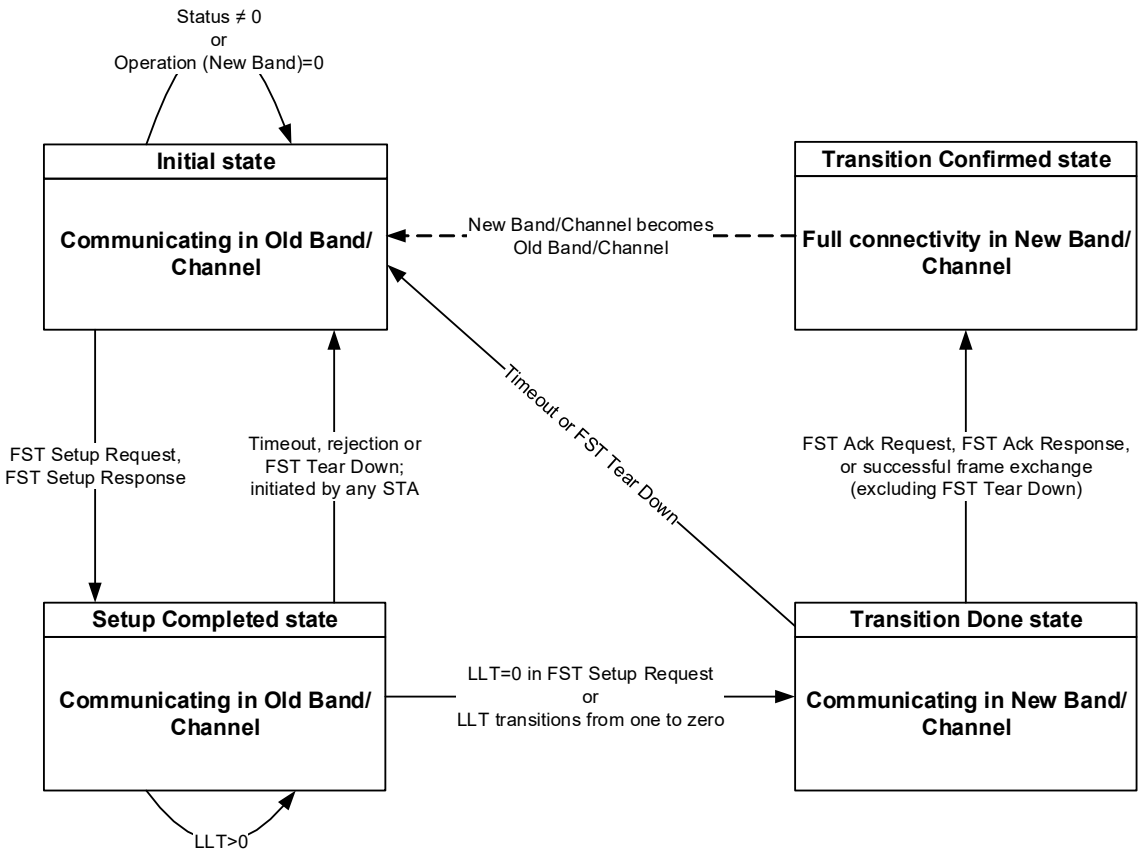

Figure 11-91—States of the FST setup protocol

PENDING_ADMITTING_FST_SESSION or PENDING_GAP_IN_BA_WINDOW. In the latter case, the responder shall transmit the unsolicited FST Setup Response frame to the initiator.

There might be multiple FST Setup Request and FST Setup Response frame transmissions by the initiator and the responder, respectively, until the FST session between these STAs becomes established. At each transition, or attempt to transition, from the Initial state to the Setup Completed state, the initiator and responder shall perform the following procedure:

a) The initiator sends an FST Setup Request frame to the responder.

b) Upon receipt of an FST Setup Request frame, the responder shall respond with an FST Setup Response frame unless it has a pending FST Setup Request frame addressed to the initiator and the responder has a numerically larger MAC address (see 12.7.1.1 for comparison of MAC addresses) than the initiator's MAC address, in which case the responder shall discard the received FST Setup Request frame.

c) If, after the reception of the acknowledgment to the initiator's FST Setup Request frame, the initiator receives an FST Setup Request frame from the responder, the initiator shall not respond with an FST Setup Response frame if its MAC address is numerically larger (see 12.7.1.1 for comparison of MAC addresses and see 11.1.4.3.10) than the responder's MAC address. Otherwise, if its MAC address is numerically smaller than the responder's MAC address, it becomes the responder and shall respond with an FST Setup Response frame and shall not send the FST Setup Request frame during the current FST.

d) The initiator shall not move to the Setup Completed state if at least one of the following conditions is met:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

1) The initiator does not receive an FST Setup Response frame from the responder within the STT.
2) The Status Code field in the received FST Setup Response frame from the responder is different from SUCCESS.
3) A state-specific exception in Table 11-25 takes place.

e) The initiator shall move to the Setup Completed state if none of conditions d(1), d(2), and d(3) is met.

f) The responder shall not move to the Setup Completed state if at least one of the following conditions is met:
1) The responder does not receive the acknowledgment to its transmitted FST Setup Response frame
2) The Status Code field in the FST Setup Response frame it transmitted to the initiator was different from SUCCESS.
3) The value of the Setup and Operation subfields within the Session Transition element in the transmitted FST Setup Response frame results in a status different from any of the rows shown in Figure 11-26 , in which case the responder shall set the Status Code field with the transmitted FST Setup Response frame to REQUEST_DECLINED.
4) The resulting status of the Operation subfield in the New Band field is 0.

g) The responder shall move to the Setup Completed state if none of conditions f)1), f)2), f)3), and f)4) is met.

Table 11-25—Exceptions for the initiator

State	Condition	Meaning	Next state
Initial	FST Setup Response frame with Status Code PENDING_ADMITTING_FST_SESSION	Pending, responder in process of admitting FST session.	Initial
Initial	FST Setup Response frame with Status Code PENDING_GAP_IN_BA_WINDOW	Pending, block ack window at the responder has gaps.	Initial
Initial	FST Setup Response frame with Status Code REJECTED_WITH_SUGGESTED_CHANGES	One or more parameters of the FST Setup Request frame is invalid and the responder suggests alternative parameters.	Initial
Initial	FST Setup Response frame with Status Code REQUEST_DECLINED	Responder rejects the request. One particular case is that values of the operating class and channel number fields within the Multi-band element, if any, received in the FST Setup Request frame is different from the corresponding fields within the Multi-band element, if any, transmitted in the following FST Setup Response.	Initial
Initial	FST Setup Response frame with Status Code REJECT_DSE_BAND	Responder rejects the request since the initiator is a dependent STA and the request is for transitioning to a frequency band subject to DSE procedures. In the rejection, the responder can include a TIE.	Initial

Table 11-25—Exceptions for the initiator *(continued)*

State	Condition	Meaning	Next state
Initial	Resulting status is different from shown in Table 11-26	The responder is not able to complete the setup.	Initial
Initial	Resulting status of the Operation field in the New Band field is 0 in Table 11-26	The operation in the new band is disabled.	Initial
Setup Completed	FST Setup Response frame with Status Code SUCCESS and LLT field within the FST Setup Request frame is greater than zero	The STA is ready to switch to the new band if the link is lost in the old band.	Setup Completed
Setup Completed	Transmission or reception of FST Teardown frame	Termination of FST session.	Initial

If, upon transition to the Setup Completed state, the LLT field within the last successful FST Setup Request frame received by the responder or transmitted by the initiator was equal to 0, the initiator and responder shall immediately move to the Transition Done state.

If, upon transition to the Setup Completed state, the LLT field within the last successful FST Setup Request frame received by the responder or transmitted by the initiator was greater than 0, the initiator and responder shall proceed as follows:

— If the last FST Setup Request or FST Setup Response frames exchanged between the initiator and responder included a Switching Stream element, then all of the streams within the Switching Stream element that have the LLT Type field set to 1 shall be switched using the Stream-based Link Loss Countdown, and all of the streams within the Switching Stream element that have the LLT Type field set to 0 shall be switched using the STA-based Link Loss Countdown.

— If the neither the FST Setup Request nor the FST Setup Response frames exchanged between the initiator and responder included a Switching Stream element, then the streams shall be switched using the STA-based Link Loss Countdown.

The state transition for the STA, if STA-based, or the stream, if stream-based, from the Setup Completed state to the Transition Done state shall occur immediately after the corresponding Link Loss countdown timer transitions from 1 to 0 within any of the initiator or responder of the FST session.

An initiator and responder shall perform the STA-based and stream-based Link Loss Countdown as follows:

— STA-based Link Loss Countdown: Both initiator and responder shall remain in the Setup Completed state and start a Link Loss countdown timer with an initial value of LLT×32 μs. The Link Loss countdown is reloaded with the value of LLT×32 μs every time that an individually addressed frame is received from the peer STA of the FST session.

— Stream-based Link Loss Countdown: Both the initiator and responder shall start a Link Loss countdown timer with an initial value of LLT×32 μs for each stream identified within the Switching Stream element. The Link Loss countdown for a stream is reloaded with the value of LLT×32 μs every time that an individually addressed frame for that stream is received from the peer STA of the FST session.

Before leaving the Setup Completed state, an initiator and/or responder that is performing a full FST may transmit an FST Setup Response frame in the old band/channel with the Status Code field set to

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

PERFORMING_FST_NOW and with the RA field set to the broadcast address to notify other STAs in the BSS of the STA's forthcoming full FST.

Table 11-26 shows the FST session status at each state transition. The Setup and Operation subfields shown in Table 11-26 are present within the Session Transition element. When the value of a subfield in the FST Setup Request frame is different from the value of that same subfield in the following FST Setup Response frame, the resulting status shall be the logical AND of the value of the corresponding subfields in both the FST Setup Request and the FST Setup Response frames.

Table 11-26—FST status at state transition

From State	Old band resulting status		New band resulting status		To State	Definition
	Setup	Operation	Setup	Operation		
Initial	1	1	0	0	Initial	New band setup and operation are disabled.
Initial	1	1	1	0	Initial	New band operation is disabled, the setup is kept alive.
Initial	0	0	1[a]	1	Setup Completed	FST session is operational in new band.
Initial	1[a]	1	1[a]	1	Setup Completed	FST session is operational in both bands.
Initial	1	0	1[a]	1	Setup Completed	FST session is operational in new band; FST session in old band is kept alive.
Setup Completed	Unchanged	Unchanged	Unchanged	Unchanged	Transition Done	No status changes.
Transition Done	Unchanged	Unchanged	Unchanged	Unchanged	Transition Confirmed	No status changes.

[a] The value of this field remains unchanged during the FST.

Upon transition to the Transition Done state and if transparent FST is used, the association state (see 11.3.1) of the STA corresponding to the old band/channel is transferred to the STA corresponding to the new band/channel.

To transition from the Transition Done state to the Transition Confirmed state, the initiator and responder shall perform the following procedure within the channel number of the operating class and band ID specified in the Multi-band element negotiated during the FST session setup:

a) The state transition is controlled by the State Transition Timer (STT). Each STA of the FST session has its own STT. The initiator shall transition to the Initial state when its STT transitions from 1 to 0, but not when the STT is set to 0. The responder shall transition to the Initial state when its STT transitions from 1 to 0, but not when the STT is set to 0.

   The initiator shall set the STT to the value of the FSTSessionTimeout field at successful transmission of an FST Ack Request frame or at transmission of any individually addressed MPDU

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

to the responder. The initiator shall set the STT to 0 at the transmission of an Ack frame sent in response to an FST Ack Response frame from the responder or at reception of an Ack frame received in response to a frame sent to the responder.

The responder shall set the STT to FSTSessionTimeout at transmission of an FST Ack Response frame or at transmission of any other individually addressed MPDU to the initiator. The responder shall set the STT to 0 at the reception of an Ack frame received in response to a transmitted FST Ack Response frame or at the reception of any individually addressed frame sent by the initiator. The responder shall transmit an FST Ack Response frame to the initiator no later than FSTSessionTimeout after the transmission of an Ack frame sent in response to an FST Ack Request frame from the initiator.

b) The SME of both the initiator and responder generates an MLME-FST-INCOMING.request primitive that includes the parameters of the FST. This primitive shall be generated to the MLME associated with the channel number, operating class, and band ID specified in the Multi-band element negotiated during the FST session setup. This primitive notifies the MLME of an impending FST.

c) The initiator shall send an FST Ack Request frame or may send any other individually addressed MPDU to the responder.

NOTE 1—Depending on the BSS configuration in the new band/channel, the initiator might have to associate and/or authenticate with the BSS before it is allowed to transmit a frame to the responder.

d) Upon receipt of an FST Ack Request frame, the responder shall respond to the initiator with an FST Ack Response frame.

NOTE 2—Depending on the BSS configuration in the new band/channel, the responder might have to associate and/or authenticate with the BSS before it is allowed to transmit a frame to the initiator.

e) The initiator shall move to the Transition Confirmed state
   1) Upon transmission of an Ack frame sent in response to any individually addressed frame, including an FST Ack Response frame, received from the responder; or
   2) When the initiator receives an Ack frame from the responder to any non-FST Ack Request frame the initiator transmitted to the responder.

f) The responder shall move to the Transition Confirmed state
   1) When the responder receives an Ack frame in response to any individually addressed frame, including an FST Ack Response frame, sent to the initiator; or
   2) Upon transmission of an Ack frame sent in response to any individually addressed non-FST Ack Request frame.

Following the transition to the Transition Confirmed state, a STA shall adopt the role indicated in the STA Role field corresponding to the channel number, operating class and band ID that was last transmitted to the peer STA within the Multi-band element. If the STA was operating within a PBSS, was the initiator of the FST session, and the new role of the STA is as an IBSS STA, then the STA shall be a DFS Owner of the IBSS.

In case the transition to the Transition Confirmed state was the result of a Stream-based Link Loss Countdown, the stream shall remain in the Transition Confirmed state until all of the streams included within the corresponding Switching Stream element reach the Transition Confirmed state. Once all streams within the corresponding Switching Stream element reach the Transition Confirmed state or the FST session ceases to exist, the STA moves to the Initial state.

If neither the initiator nor the responder perform in the role of AP or PCP as indicated through the STA Role field within the Multi-band element corresponding to the new band for that STA, one of the STAs can initialize a new BSS (11.1) on the new band for communication between the STAs.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the Switch Intent field in the last Session Transition element transmitted to a responder is 1, an initiator may switch to the new band and channel indicated in the last transmitted FST Setup Request frame and Multi-band element, respectively, if at least one of the following conditions is satisfied:

— The Status Code field within the FST Setup Response frame received in response to the transmitted FST Setup Request frame is equal to REQUEST_DECLINED.

— The initiator moves to the Initial state due to the STT at the initiator moving from 1 to 0.

— The initiator moves to the Initial state due to the reception of an FST Teardown frame from the responder.

Immediately before an initiator switches to a new band and/or channel, the initiator shall disassociate and delete all TS and block ack agreement(s) it has with a responder for which at least one of the above conditions is met.

Following the successful fast session transfer to a new band, the STA of the FST session shall follow the medium access rules applicable to the new band.

11.31.3.3 FST TS switching

If a STA transmitting an FST Setup Request frame or an FST Setup Response frame does not intend to switch all its streams, then the STA shall include the Switching Stream element in the transmitted frame to indicate which streams are requested to be transferred to the other band/channel. If the FST Setup Request frame includes a Switching Stream element, the FST Setup Response frame should include a Switching Stream element. If the FST Setup Request frame does not include a Switching Stream element, the FST Setup Response frame may include a Switching Stream element. If the STA transmitting the Switching Stream element has not set up a stream in the band indicated in the New Band ID field within this element, it shall set the Stream ID In New Band Valid field to 0. A STA may set up a stream in any band/channel by transmitting ADDBA Request or ADDTS Request frames that include the Multi-band element.

If a STA transmits an ADDTS Request frame to another STA with which it has established an FST session and the ADDTS Request frame is transmitted in a band or channel different from the band or channel to which the ADDTS request is intended to apply, the ADDTS Request frame shall include the Multi-band element with the Band ID, Operating Class, and Channel Number fields set to indicate to which channel the ADDTS Request frame applies. In addition, if these STAs use the nontransparent mode for FST, the STA transmitting the ADDTS Request frame sets the STA MAC Address Present field to 1 and the STA MAC Address field to the MAC address that the STA uses in the band and channel number that are indicated in the Multi-band element contained in the ADDTS Request frame. Similar to the ADDTS Request frame, the Multi-band element shall be included in the ADDBA Request, ADDTS Response, ADDBA Response, DELTS, and DELBA frames when these frames are transmitted in a band or channel different from the band or channel to which they are intended to apply.

When using transparent mode to transfer an FST session corresponding to a TID/TSID, the Direction subfield within the TSPEC element, if any, used to set up the TID/TSID should not be set to indicate a bidirectional link. This enables the SME to use the TID/TSID in conjunction with the source and destination MAC addresses in both the old and new frequency band/channel to uniquely identify the FST session.

If any of the ADDTS variants is used to switch the TS, then the PTP TSPEC or the DMG TSPEC shall be used when the TS is being established to operate in a DMG BSS, and the Basic TSPEC shall be used when the TS is being established to operate in a non-DMG BSS irrespective of the band and channel used to communicate the ADDTS frames and the DMG ADDTS frames.

The rules defined below apply when the ADDTS frames or the DMG ADDTS frames are used to switch TS. When the ADDTS frames and the DMG ADDTS frames are used, then the ADDTS requester and the ADDTS responder provide the functions defined for the ADDBA originator and the ADDBA recipient, respectively.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the ADDBA recipient includes the Switching Stream element in any of the FST Setup Request or FST Setup Response frames and if the Stream ID In New Band Valid field within the Switching Stream element is 0, the ADDBA originator should issue the DELBA frame to reject the block ack agreements indicated in the Stream ID In Old Band field. If the originator intends to establish new block ack agreements in the band indicated in the Multi-band element sent by the recipient and with the recipient MAC address indicated in the Multi-band element sent by the recipient, the originator shall transmit an ADDBA Request frame addressed to the recipient.

The originator may include the Multi-band element and the Ethernet type TCLAS element in the ADDBA Request frame. If the MAC Addresses of the originator and recipient to be used in the new band are different from the MAC addresses used in the old band, then the ADDBA Request frame sent in the old band to establish a block ack agreement in the new band shall include the Multi-band and the TCLAS elements. The resulting block ack agreement, if established, applies to the band and channel identified in the Multi-band element included in the ADDBA Request frame. The BlockAck is identified by the TID/TSID and MAC addresses of the originator and the recipient used in the band and channel indicated in the Multi-band element included in ADDBA Request and ADDBA Response frames.

The ADDBA Request frame may be issued in the old band and channel, and the corresponding ADDBA Response frame may be transmitted in the band and channel indicated in the Multi-band element within the ADDBA Request frame.

The following rules for establishment of a multi-band block ack agreement shall apply:

a) If the TA and/or the RA fields of the ADDBA Request frame are different from the originator MAC address and/or the recipient MAC address, respectively, used in the channel and band where the block ack agreement should operate, then the originator shall set the Source Address field and the Destination Address field of the classifier to the originator MAC address and the recipient MAC address, respectively, to be used in the band and channel indicated in the Multi-band element included in the ADDBA Request frame.

b) If the TA and RA are equal to the originator MAC address and the recipient MAC address, respectively, then the Multi-band element, if any, included in the ADDBA Request frame shall indicate the band and channel over which the block ack agreement is to operate. The TCLAS element shall not be included in this ADDBA Request frame.

c) The Multi-band element should not be included in the ADDBA Request frame if in the case b) the ADDBA Request frame is issued in the same band and channel over which the block ack agreement is to operate.

d) If the TA and/or the RA fields of the ADDBA Response frame are different from the recipient MAC address and/or the originator MAC address, respectively, to be used in the channel and band where the block ack agreement should operate, then the recipient shall set the Source Address field and the Destination Address field of the classifier to the recipient MAC Address and the originator MAC address, respectively, to be used in the band and channel indicated in the Multi-band element included in the ADDBA Response frame. The indicated band and channel shall be equal to the band and channel indicated in the Multi-band element of the ADDBA Request frame.

e) If the TA and RA fields are equal to the recipient MAC address and the originator MAC address, respectively, then the Multi-band element, if any, included in the ADDBA Response frame shall indicate the band and channel over which the block ack agreement is to operate. The indicated band and channel shall be equal to the band and channel indicated in the Multi-band element of the ADDBA Request frame. The TCLAS element shall not be included in the ADDBA Response frame.

f) The Multi-band element should not be included in the ADDBA Response frame if in case e) the ADDBA Response frame is issued in the same band and channel over which the block ack agreement is to operate.

11.31.4 FST teardown

At the Setup Completed state or Transition Done state, a STA may transmit an FST Teardown frame to its peer STA of the FST session in order to tear down an FST session that was previously set up using the FST Setup Request/Response frame exchange. Upon transmission or reception of an FST Teardown frame, the initiator and responder move to the Initial state (11.31.3). When moving to the Initial state and if the Switch Intent field in the last Session Transition element transmitted to a responder is 1, the initiator behaves as described in 11.31.3.2.

11.31.5 On-channel Tunneling (OCT) operation

OCT allows the following:

— A STA of a multi-band capable device or a STA that is in the same device as another STA to transmit or forward an MMPDU that was constructed by, addressed by, or addressed to a different STA in the same device.

— An AP to transmit or forward an MMPDU that was constructed by, addressed by, or addressed to another AP if either one of the APs sends a Reduced Neighbor Report element with a TBTT Information field describing the other AP or if either one of the APs sends a Neighbor Report element describing the other AP, and where both APs support OCT.

An MMPDU transmitted this way is referred to as an *OCT MMPDU*. The MLME of the nontransmitting STA that constructs or is the destination of an OCT MMPDU is referred to as an *NT-MLME*. The MLME of the STA that transmits or receives an OCT MMPDU over the air is referred to as a *TR-MLME*. An NT-MLME that constructs an OCT MMPDU destined to a peer NT-MLME does so according to the capabilities of the STA that contains the peer NT-MLME.

NOTE 1—OCT can be used in conjunction with or independent from the FST setup protocol.

Either of the following conditions indicates that a STA supports OCT and has dot11OCTOptionImplemented equal to true:

— A STA supports OCT if the OCT Not Supported subfield within the STA's Multi-band element is 0.

— A non-AP STA supports OCT if the OCT field is equal to true in the Extended Capabilities elements it transmits.

— If a reporting AP sends a frame with a Reduced Neighbor Report element with a TBTT Information field describing a reported AP that has the OCT Recommended subfield equal to 1, then both the reporting AP and the reported AP support OCT.

— If a reporting AP sends a frame with a Neighbor Report element describing a reported AP that has the OCT Supported With Reporting AP subfield equal to 1, then both the reporting AP and the reported AP support OCT.

A STA should not perform OCT with a peer STA that does not support OCT. A STA that does not support OCT shall ignore a received OCT MMPDU.

Figure 11-92 depicts the overall OCT procedure. In this figure, <primitive> refers to the name of any of the MLME primitives defined in 6.4 that meets all of the following conditions:

— Includes a peer Multi-band element. The peer Multi-band element is used to identify the peer NT-MLME.

— Includes a local Multi-band element. The local Multi-band element is used to identify the local TR-MLME.

An MLME primitive meeting all of the above conditions is referred to as an *OCT MLME primitive*.

[1] Primitive invoked if defined. If not defined, invocation is not present.

Figure 11-92—On-channel tunneling procedure

NOTE 2—MLME-AUTHENTICATE, MLME-ASSOCIATE, and MLME-REASSOCIATE are examples of primitives that are OCT MLME primitives.

The OCT procedure can be used both with the OCT MLME primitives and to transmit a response to an On-channel Tunnel Request frame tunneling a Probe Request frame. The Timestamp field of the Probe Response frame tunneled in an On-channel Tunnel Request frame is reserved.

To perform the OCT procedure, the values of the Band ID, Channel Number and BSSID fields in a Multi-band element or OCT Source element are used to identify an MLME. All other fields in the Multi-band element shall be reserved.

Except for the following cases, the values of the Band ID, Channel Number and BSSID fields in a Multi-band element or OCT Source element are used by an NT-MLME to deliver messages to a TR-MLME through the OCTunnel.request primitive, and are used by a TR-MLME to deliver messages to an NT-MLME through the OCTunnel.indication primitive:

— If the BSSID field is the wildcard BSSID, an MLME (either TR-MLME or NT-MLME) shall not use the BSSID field in selecting the MLME to deliver a message and shall, instead, invoke the corresponding primitive for all MLMEs that match the Band ID and Channel Number fields.

— If the OCT MLME request primitive is the MLME-SCAN.request primitive with ScanType parameter set to ACTIVE and that includes the ChannelList parameter, the NT-MLME shall not use the Channel Number field within the Multi-band local parameter of the MLME-SCAN.request primitive in selecting the TR-MLME to deliver a message and shall, instead, invoke the OCTunnel.request primitive at the TR-MLME(s) that match the Band ID field and BSSID field within Multi-band local parameter, and the channels specified in the ChannelList parameter.

— If the Channel Number field is 0 and the OCT MLME request primitive is not the MLME-SCAN.request primitive with ScanType parameter set to ACTIVE and that includes the ChannelList parameter, an MLME (either TR-MLME or NT-MLME) shall not use the Channel Number field in selecting the MLME to deliver a message and shall, instead, invoke the corresponding primitive for all MLMEs that match the Band ID and BSSID fields.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— If the Channel Number field is 0 and the OCT MLME request primitive is not the MLME-SCAN.request primitive with ScanType parameter set to ACTIVE and that includes the ChannelList parameter, and the BSSID field is the wildcard BSSID, an MLME (either TR-MLME or NT-MLME) shall use neither the BSSID field nor the Channel Number field in selecting the MLME to deliver a message and shall, instead, invoke the corresponding primitive for all MLMEs that match the Band ID field.

In the following procedure, a "request tunneled MMPDU" is an MMPDU generated in the context of an MLME.request primitive. A "response tunneled MMPDU" is an MMPDU generated in the context of an MLME.response primitive.

To transmit a tunneled MMPDU, the SME of a STA that supports OCT generates an OCT MLME request primitive that includes the peer Multi-band element and the local Multi-band element. If the OCT MLME request primitive is the MLME-SCAN.request primitive with the ScanType parameter set to ACTIVE, the BSSID field within the peer Multi-band element shall be set to the value of the BSSID parameter in the MLME-SCAN.request primitive and the BSSID field within the local Multi-band element shall be set to an individual address.

An NT-MLME receiving an OCT MLME request primitive shall

— As defined in this standard, process the request and construct an OCT MMPDU corresponding to the primitive in question. The NT-MLME shall not transmit any frame as a result of this primitive.
— Generate an MLME-OCTunnel.request primitive with parameters including the OCT MMPDU, the Multi-band peer parameter set to the peer Multi-band element and the OCT source parameter set to the OCT Source element identifying the NT-MLME.

An NT-MLME does not issue an MLME-OCTunnel.request primitive if a selected TR-MLME does not exist. A TR-MLME does not issue an MLME-OCTunnel.indication primitive if a selected NT-MLME does not exist.

A single OCT MLME request primitive received by an NT-MLME may result in the invocation of one or more MLME-OCTunnel.request primitives at TR-MLME(s). Each invocation shall be towards a different TR-MLME.

A TR-MLME receiving an MLME-OCTunnel.request primitive with a request tunneled MMPDU shall transmit an On-channel Tunnel Request frame addressed to the peer TR-MLME and which includes the tunneled MMPDU. The peer TR-MLME(s) is identified by the PeerSTAAddress parameter of the MLME-OCTunnel.request primitive. The On-channel Tunnel Request frame shall not be group addressed. Once the On-channel Tunnel Request frame is transmitted and acknowledged or attempts to transmit the frame are abandoned, the TR-MLME shall issue an MLME-OCTunnel.confirm primitive, with the appropriate result code, to inform the NT-MLME of the outcome of the frame transmission.

A receiving TR-MLME shall discard the received On-channel Tunnel Request frame if that frame is not targeting an NT-MLME in the same multi-band capable device as the TR-MLME.

NOTE 3—The mechanism for a TR-MLME to forward an OCT MMPDU received in an On-channel Tunnel Request frame to an NT-MLME not in the same multi-band capable device as the TR-MLME is outside the scope of this standard.

A TR-MLME receiving an On-channel Tunnel Request frame carrying a request tunneled MMPDU shall generate an MLME-OCTunnel.indication primitive with the Multi-band local parameter set to the Multi-band element identifying the TR-MLME, the OCT source parameter set to the value of the OCT Source field contained in the On-channel Tunnel Request frame and the Tunneled RXVECTOR parameter set to the RXVECTOR of the On-channel Tunnel Request frame. The MLME-OCTunnel.indication primitive shall be generated to the NT-MLME identified by the peer Multi-band element contained within the received On-channel Tunnel Request frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

An NT-MLME receiving an MLME-OCTunnel.indication primitive carrying a request tunneled MMPDU shall

- As defined in this standard, process the OCT MMPDU parameter of the primitive as if the MMPDU had been received over the air, with the exception that an acknowledgment, if any, shall not be sent as a response to the reception of the MMPDU.
- Generate an OCT MLME indication primitive, if one is defined, corresponding to the frame type of tunneled MMPDU. This primitive is generated to the SME of the STA, which processes the MMPDU as defined in this standard. The Multi-band local parameter of the OCT MLME indication primitive shall be set to the value of the Multi-band local parameter of the MLME-OCTunnel.indication primitive and the Multi-band peer parameter shall be set to a Multi-band element where the value of the Band ID, Channel Number and BSSID fields are set to the value of the corresponding fields in the OCT source parameter of the MLME-OCTunnel.indication primitive.

In the case of a .request/.indication primitive, the process stops here. Otherwise, the process continues as described below.

The peer SME responds to the reception of an OCT MLME indication primitive by generating the corresponding OCT MLME response primitive. This response includes the peer Multi-band element and the local Multi-band element.

An NT-MLME receiving an OCT MLME response primitive, if one is defined, or generating a response by itself, if no OCT MLME response primitive is defined (e.g., MLME-SCAN.response is not defined), shall

- As defined in this standard, process the response and construct an OCT MMPDU corresponding to the primitive in question. The NT-MLME shall not transmit any frame as a result of this primitive.
- Generate an MLME-OCTunnel.request primitive with parameters including the OCT MMPDU, the Multi-band peer parameter set to the peer Multi-band element and the OCT source parameter set to the OCT Source element identifying the NT-MLME. If no OCT MLME response primitive is defined, the Multi-band peer parameter shall be set to a Multi-band element where the value of the Band ID, Channel Number and BSSID fields are set to the value of the corresponding fields in the OCT source parameter received in the corresponding MLME-OCTunnel.indication primitive. The MLME-OCTunnel.request primitive shall be generated to the TR-MLME identified by the local Multi-band element specified in the OCT MLME response primitive, if one is defined, or to the TR-MLME identified by the Multi-band local parameter of the MLME-OCTunnel.indication primitive that triggered this response, if no OCT MLME response primitive is defined.

A TR-MLME receiving an MLME-OCTunnel.request primitive with a response tunneled MMPDU shall transmit an On-channel Tunnel Request frame addressed to the peer TR-MLME that includes the tunneled MMPDU. The peer TR-MLME(s) is identified by the PeerSTAAddress parameter of the MLME-OCTunnel.request primitive. Once the On-channel Tunnel Request frame is transmitted and acknowledged or attempts to transmit the frame are abandoned, the TR-MLME shall issue an MLME-OCTunnel.confirm primitive, with the appropriate result code, to inform the NT-MLME of the outcome of the frame transmission.

A TR-MLME receiving an On-channel Tunnel Request frame carrying a response tunneled MMPDU shall generate an MLME-OCTunnel.indication primitive with the Multi-band local parameter set to the Multi-band element identifying the TR-MLME, the OCT source parameter set to the value of the OCT Source field contained in the On-channel Tunnel Request frame and the Tunneled RXVECTOR parameter set to the RXVECTOR of the On-channel Tunnel Request frame. The MLME-OCTunnel.indication primitive shall be generated to the NT-MLME identified by the peer Multi-band element contained within the received On-channel Tunnel Request frame.

An NT-MLME receiving an MLME-OCTunnel.indication primitive carrying a response tunneled MMPDU shall

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— Process the OCT MMPDU parameter of the primitive as if the MMPDU had been received over the air.

— Generate an OCT MLME confirm primitive, if one is defined, corresponding to the frame type of the tunneled MMPDU. This primitive is directed at the SME and has the Multi-band local parameter set to the value of the Multi-band local parameter of the MLME-OCTunnel.indication primitive and the Multi-band peer parameter set to a Multi-band element where the value of the Band ID, Channel Number and BSSID fields are set to the value of the corresponding fields in the OCT source parameter of the MLME-OCTunnel.indication primitive. If the OCT MLME confirm primitive is the MLME-SCAN.confirm primitive and the NT-MLME did not scan all the channels specified in the corresponding MLME-SCAN.request primitive, the ResultCode parameter in the MLME-SCAN.confirm primitive shall be set to PARTIAL_SCAN and the ScannedChannelList parameter shall list all channels that have been scanned.

An NT-MLME receiving an MLME-OCTunnel.confirm primitive shall:

— As defined in this standard, take action, if there is one, based on the success or otherwise of the OCT MMPDU transmission by the TR-MLME.

Figure 11-93 and Figure 11-94 illustrate the complete forwarding of OCT messages based on the procedure described above in this subclause. Figure 11-93 depicts the forward path, i.e., from a requesting multi-band device (MBD) that initiates the OCT procedure with a responding MBD. Figure 11-94 depicts the return path, i.e., from a responding MBD that generates an OCT MMPDU in response to an OCT MMPDU from a requesting MBD.

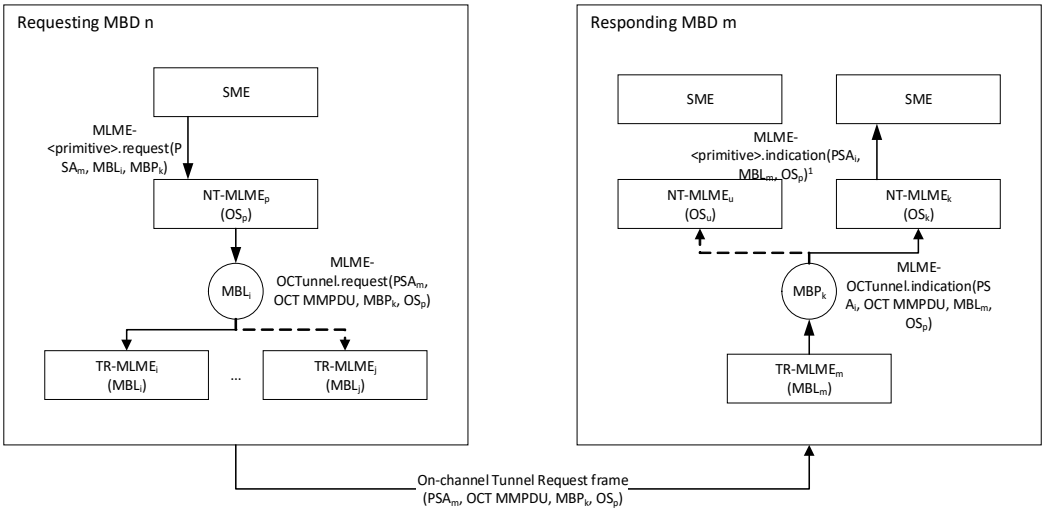

Figure 11-93—Forward path of OCT messages based on OCT parameters

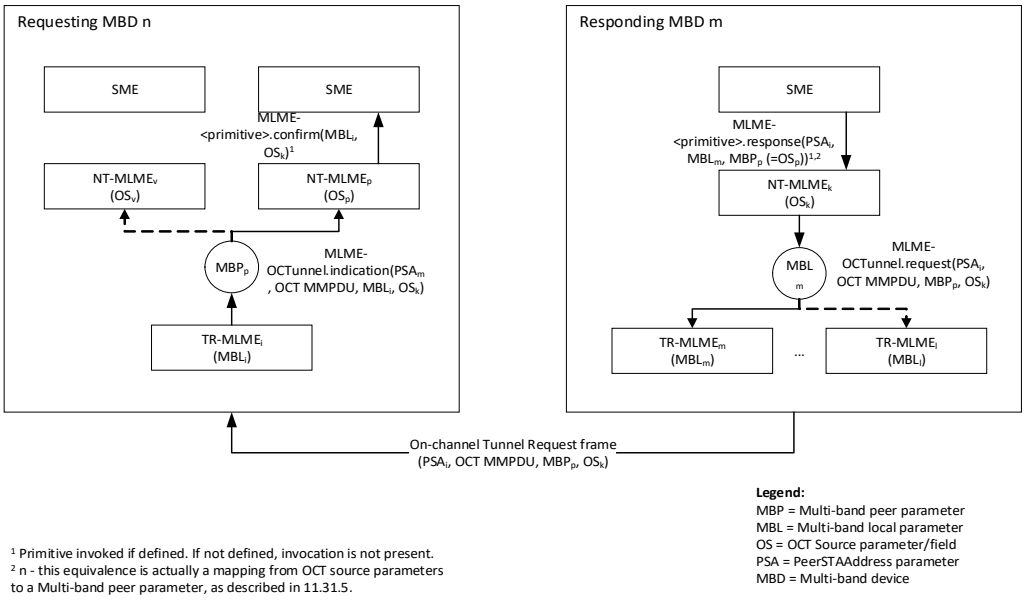

Figure 11-94—Return path of OCT messages based on OCT parameters

11.31.6 FST payload

When FST Action frames are forwarded by an AP, FST uses MSDUs with EtherType 89-0d as defined in Annex H. In this case, the Payload field of the MSDUs contains an FST Action frame body as is specified in 9.6.20.

11.31.7 Multi-band discovery assistance procedure

11.31.7.1 Multi-band discovery assistance request procedure

The multi-band discovery assistance procedure allows discovery of DMG BSSs using a STA of a multi-band capable device that operates on a band other than its intended band of communication.

A device is multi-band discovery assistance capable if the value of both dot11MultibandImplemented and dot11DiscoveryAssistanceActivated are true for all discovery assistance cooperating STAs in the device. A STA that is part of a multi-band discovery assistance capable device shall advertise the capability of multi-band discovery assistance by setting the Discovery Assistance Enabled subfield in the Multi-band Control field of its Multi-band element to 1.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Figure 11-95 depicts an example of the overall multi-band discovery assistance procedure.

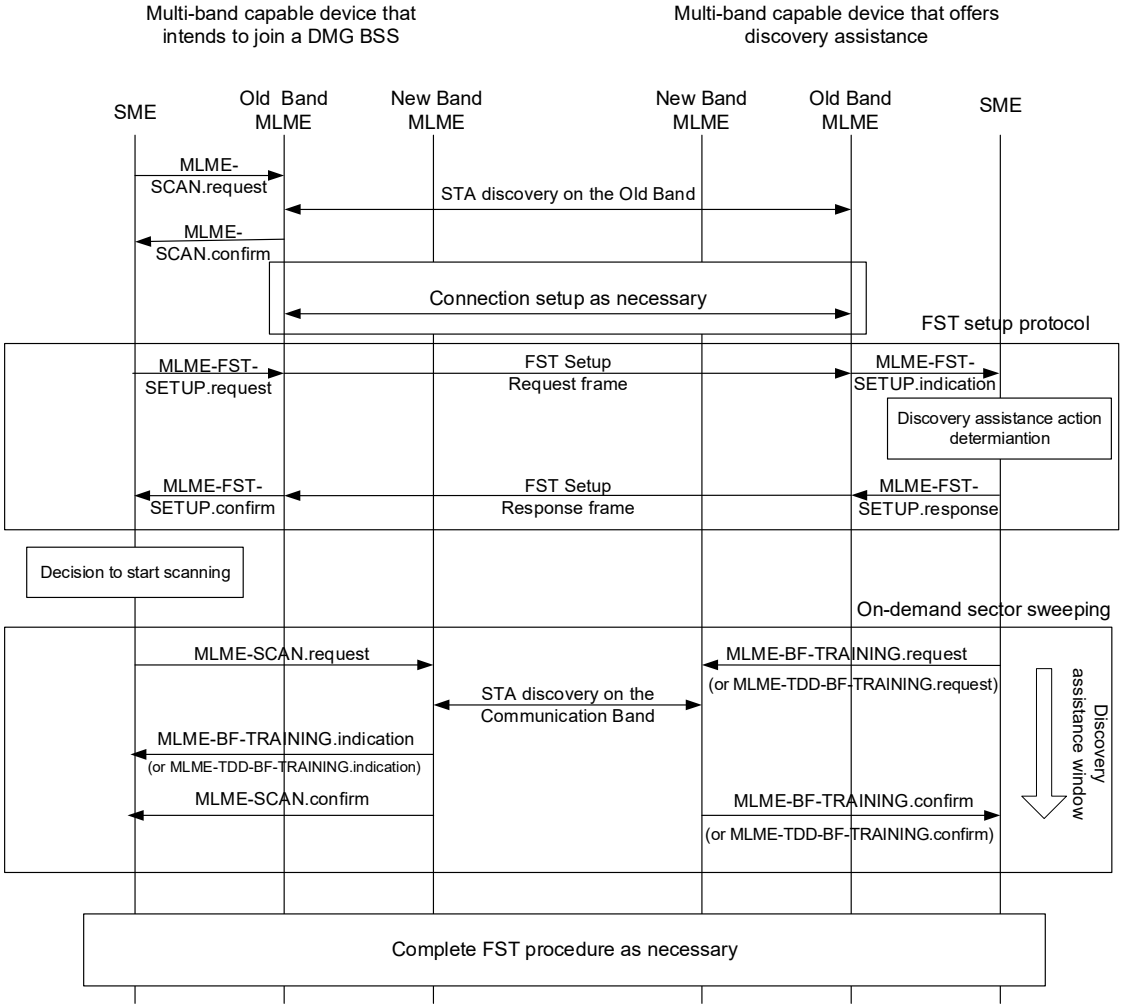

Figure 11-95—Multi-band discovery assistance procedure

The SME of a STA of a multi-band capable device that intends to join a DMG BSS issues an MLME-SCAN.request primitive to the *Old Band MLME* of the device. After the scanning procedure completes, the *Old Band MLME* issues an MLME-SCAN.confirm primitive to the SME of the STA. The MLME-SCAN.confirm primitive contains information indicating which STAs support multi-band discovery assistance and for which band, i.e., the Discovery Assistance Enabled subfield in the Multi-band Control field of the Multi-band element.

If a multi-band discovery assistance capable device is found and a STA of the device operates a DMG BSS or an EDMG BSS, the SME of the STA that performed scanning may issue MLME-FST-SETUP.request primitive to the *Old Band MLME* of the STA to request the discovered STA to start the discovery assistance procedure with its DMG STA. The *Old Band MLME* receiving the MLME-FST-SETUP.request primitive shall transmit an FST Setup Request frame.

NOTE—If the recipient of an FST Setup Request frame is an AP, the STA transmitting the FST Setup Request frame needs to complete the association and authentication process before transmitting the frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The two multi-band capable devices exchange FST Setup Request frame and FST Setup Response frames, as described in 11.31.3 (FST setup protocol), containing the DMG Discovery Assistance element.

Upon reception of the MLME-FST-SETUP.indication primitive, the SME of the STA that received the discovery assistance request determines if it accepts the requested discovery assistance. The SME shall encode the determination results in the DMG Discovery Assistance element, and issue an MLME-FST-SETUP.response primitive to the *Old Band MLME* to send back discovery assistance response.

The SME that received the MLME-FST-SETUP.confirm primitive including the DMG Discovery Assistance element shall determine if the discovery assistance response indicates that the discovery assistance is accepted. If it has been accepted, the device shall start its DMG STA on the channel specified in the Multi-band element. Further, the SME of the DMG STA shall issue an MLME-SCAN.request primitive to its *New Band MLME* in accordance with the parameters contained in the elements in the received frame.

Upon the successful completion of the on demand sector sweeping, the two multi-band devices may complete the FST procedure as described in 11.31.3 (FST setup protocol).

11.31.7.2 Discovery assistance action determination and on demand sector sweeping

When the SME receiving the discovery assistance request accepts the request, it shall set the Discovery Assistance Request Status Code field of the DMG Discovery Assistance element transmitted in the FST Setup Response frame containing the discovery assistance response to SUCCESS and take one of the following actions with the corresponding DMG STA.

If the DMG STA operates non-TDD channel access, the DMG STA shall provide discovery assistance through one of the following two options:

- Option 1: The DMG STA schedules DMG Beacon frame transmissions sweeping all of its sectors so that the STA requesting discovery assistance can attempt to receive it. The STA sets fields in the DMG Discovery Assistance element as follows and includes it in transmitting response:
  - Sets the Discovery Assistance Type subfield in the Discovery Assistance Control field to 0.
  - Sets the Sector Sweep Start Time field to the TSF value indicating its TBTT when the discovery assistance starts.
  - Sets the Discovery Assistance Window Length to the time duration of the discovery assistance, i.e., DMG Beacon sweeping. The number of transmit antenna sectors in the STA requesting discovery assistance is used to determine the exact number of slots needed in the A-BFT period for the responder TXSS. The DMG STA might use multiple beacon intervals to complete full DMG Beacon sweeping. The Discovery Assistance Window Length might include one or more complete full DMG Beacon Sweep.
- Option 2: The DMG STA schedules a beamforming training period with the discovery assistance requesting DMG STA. The DMG STA adds the beamforming training period allocation to the Extended Schedule element and includes this element in its response. The total duration of the beamforming period shall at least cover the initiator TXSS and the responder TXSS. The DMG STA shall assign a temporary AID to the DMG STA that is requesting discovery assistance, in order to identify the STA in the element. The DMG STA sets fields in the Extended Schedule element sent in its response as follows:
  - Sets the Beamforming Training field, the IsInitiatorTXSS and IsResponderTXSS subfields in the BF Control subfield in the Allocation field to 1 to indicate that beamforming training is initiated at the start of the allocation.
  - If the DMG STA is offering discovery assistance with active scanning, it sets the Source AID subfield in the Allocation field to the temporary AID value that is assigned to the requesting DMG STA. If the DMG STA is offering discovery assistance with passive scanning, it sets the Destination AID subfield in the Allocation field to the temporary AID value that is assigned to the requesting DMG STA.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The DMG STA sets the fields in the DMG Discovery Assistance element sent in its response as follows:

- Sets the Discovery Assistance Type subfield in the Discovery Assistance Control field to 1.
- Sets the Temporary AID field to the temporary value that is assigned to the requesting DMG STA.
- Sets the Discovery Assistance Window Length to the time duration of the beamforming period, including all time blocks if more than one time block is scheduled.

If the DMG STA operates TDD channel access, the DMG STA shall provide discovery assistance through one of the following two options:

- Option 1: The DMG STA initiates TDD beamforming, as specified in 10.41.11 (TDD beamforming), with the STA that requested discovery assistance. The STA sets fields in the DMG Discovery Assistance element sent in the response as follows:
  - Sets the Discovery Assistance Type subfield in the Discovery Assistance Control field to 0.
  - Sets the Sector Sweep Start Time field to the TSF value when the STA starts TDD beamforming procedure.
  - Sets the Dwelling Time field to the recommended time to sweep the receive antenna pattern during the scanning.
  - Sets the Discovery Assistance Window Length to the time duration for the TDD beamforming. The number of DMG STA transmit antenna sectors, the number of receive antenna sectors in the STA requesting discovery assistance and the dwelling time are used to calculate the time required for TDD beamforming as described in 10.41.11 (TDD beamforming).
- Option 2: The DMG STA schedules TDD beamforming with the STA that requested discovery assistance. The DMG STA schedules the allocation as part of an Extended Schedule element and includes this element in its response. The TDD Applicable SP subfield in the Allocation Control subfield of the Allocation field in the Extended Schedule field is set to 1 and either the Source AID or the Destination AID subfields in the Allocation field in the Extended schedule element is set to the DMG STA requesting a temporary AID. The DMG STA may include a TDD Slot Structure element and a TDD Slot Schedule element in its response. The DMG STA sets fields in the DMG Discovery Assistance element sent its response as follows:
  - Sets the Discovery Assistance Type subfield in the Discovery Assistance Control field to 1.
  - Sets the Temporary AID field to a temporary value that is assigned to the requesting DMG STA. This temporary AID value is used to identify the requesting DMG STA in the Extended Schedule element.
  - Sets the Dwelling Time field to the recommended time to sweep the receive antenna pattern during the scanning.
  - Sets the Discovery Assistance Window Length to the time duration of the TDD beamforming period, including all time blocks if more than one time block is scheduled.

When a STA that is a part of a multi-band capable device receives an FST Setup Response frame with a Discovery Assistance Response element indicating SUCCESS in the Discovery Assistance Request Status Code field in the received DMG Discovery Assistance element, the STA shall take the following actions with the corresponding peer DMG STA:

- The SME shall issue an MLME-SCAN.request primitive to its New Band MLME, set the BSSID and ChannelList parameters according to the BSSID, Band ID, Operating Class and Channel Number field values captured from the Multi-band element and set the MinChannelTime parameter to the Discovery Assistance Window Length field in the received DMG Discovery Assistance element.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Depending on the values contained in the Discovery Assistance Control field in the received DMG Discovery Assistance element, the MLME-SCAN.request primitive is issued in one of the following manners:

— If the Dwelling Time Present subfield is 0 and the Discovery Assistance Type subfield is 0, the MLME-SCAN.request primitive is issued before the time specified in the Sector Sweep Start Time field in the received DMG Discovery Assistance element and the ScanType is set to passive scanning.

— If the Dwelling Time Present subfield is 0 and the Discovery Assistance Type subfield is 1, the MLME-SCAN.request primitive is issued before the time of the scheduled beamforming period specified by the Allocation field in the received Extended Schedule element. The ScanType is set to active scanning if the Source AID subfield in the Allocation field in the received Extended Scheduled element is equal to the Temporary AID field in the received DMG Discovery Assistance element. The ScanType is set to passive scanning otherwise. The DMG STA shall perform the initiator TXSS and the responder TXSS within the allocated time specified in the received Extended Schedule element.

— If the Dwelling Time Present subfield is 1 and the Discovery Assistance Type subfield is 0, the MLME-SCAN.request primitive is issued before the time specified in the Sector Sweep Start Time field in the received DMG Discovery Assistance element. The ScanType is set to TDD passive scanning, and SectorDwellTime is set to the value specified in the Dwelling Time field in the received DMG Discovery Assistance element.

— If the Dwelling Time Present subfield is 1 and the Discovery Assistance Type subfield is 1, the MLME-SCAN.request primitive is issued before the time of the scheduled beamforming period specified by the Allocation field in the received Extended Schedule element. The ScanType is set to TDD passive scanning.

The New Band MLME reports the results of the beamforming training procedure by sending an MLME-BF-TRAINING.indication primitive or MLME-TDD-BF-TRAINING.indication primitive to its SME (see 11.36 (DMG beamforming)). After the scanning procedure, the New Band MLME responds back with an MLME-SCAN.confirm primitive to its SME notifying the completion of the scanning on the New Band.

11.32 MMSL cluster operation

11.32.1 Introduction

A STA is MMSL cluster capable if it includes an MMS element in its most recent transmission of (Re)Association Request, (Re)Association Response, ADDTS Request, ADDTS Response, Probe Request, Probe Response, Information Request, or Information Response frames.

An MM-SME coordinated STA shall be MMSL cluster capable, except for an MM-SME that coordinates two STAs where one STA is a member AP or member PCP in a centralized AP or PCP cluster and the other STA is associated to the S-AP of the centralized AP or PCP cluster.

NOTE—In the centralized clustering case, the two STAs in the MM-SME are communicating with different MAC entities with different SMEs, so there is no individual link for MMSL.

A non-MM-SME coordinated STA may be MMSL cluster capable.

An MMSL cluster capable STA shall include an MMS element in transmitted (Re)Association Request and (Re)Association Response frames.

As described in 4.9.3, an MM-SME may coordinate multiple MACs (and their respective STAs).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Each STA coordinated by the same MM-SME may be used for the MMSL cluster setup and maintenance.

The PCP may deliver an MMS element that includes a MAC address that is equal to the BSSID and other MAC addresses that are not equal to the BSSID. The MAC addresses that are not the BSSID shall not be used to request and respond to association, reassociation, probing, and scheduling services provided by the PCP.

If a non-AP and non-PCP STA has delivered an MMS element to the AP or PCP, the non-AP and non-PCP STA shall not send an ADDTS Request frame to the AP or PCP with the TA field equal to a MAC address that was not included in the delivered MMS element.

If an MM-SME coordinated STA is associated with an AP or PCP that allocates one single AID to all STAs advertised in the MMS element sent by the MM-SME coordinated STA, the AID can be also used to identify the MMSL cluster. If the AID is provided for one of the advertised STAs of the MM-SME coordinated STA, then the same AID applies to all STAs whose addresses are referenced in the delivered MMS element and the Single AID field is set as per Table 9-311.

Table 11-27 covers the possible cases of the AID use for MMSL cluster identification.

Table 11-27—Setting of Single AID field

MMSL cluster configuration	Is the Single AID allocated to the MM-SME coordinated STA A?	Is the Single AID allocated to the MM-SME coordinated STA B?	AID identification of MMSL cluster
Non-AP and non-PCP MM-SME coordinated STA A is associated to PCP MM-SME coordinated STA B.	Yes	Yes	Yes
Non-AP and non-PCP MM-SME coordinated STA A and non-AP and non-PCP MM-SME coordinated STA B are both associated to the same BSS.	Yes	Yes	Yes
Non-AP and non-PCP MM-SME coordinated STA A is associated to a BSS and non-AP and non-PCP MM-SME coordinated STA B is not associated to the BSS.	Yes	No	No
Non-AP and non-PCP MM-SME coordinated STA A and non-AP and non-PCP STA B are both associated to the same BSS.	Yes	N/A	Yes
Non-AP and non-PCP MM-SME coordinated STA A is associated to a BSS and one MAC entity of non-AP and non-PCP MM-SME coordinated STA B is associated to the same BSS.	Yes	N/A	Yes

11.32.2 MMSL cluster setup

11.32.2.1 General

To establish an MMSL cluster, an MMS element of an MM-SME coordinated STA that lists its advertised STAs shall be delivered to the peer STA. The peer STA may be an MM-SME coordinated STA or a non-MM-SME coordinated STA. An MMSL cluster is identified by one of the following:

a) Advertised MAC addresses of the MAC entities of two MM-SME coordinated STAs
b) Advertised MAC addresses of the MAC entities of an MM-SME coordinated STA and of a non-MM-SME coordinated STA

In both cases, the MMS element shall be exchanged between the STAs to set up the MMSL cluster agreement.

If an MMSL cluster capable non-MM-SME coordinated STA receives an ADDTS Request frame that includes an MMS element, the SME of the non-MM-SME coordinated STA shall include the received MMS element in the MLME-ADDTS.response primitive used to send the ADDTS Response frame if the SME accepts the MMSL cluster setup. The SME of the non-MM-SME coordinated STA may set the MMS Element Owner field to “no Owner” in the MMS element included in an MLME-ASSOCIATE.request primitive and MLME-ADDTS.request primitive to establish the MMSL cluster with an MM-SME coordinated STA.

The MMS element shall be exchanged between the STAs of the MMSL cluster only once per MMSL cluster setup.

11.32.2.2 MMSL cluster setup of non-AP and non-PCP MM-SME coordinated STA with AP or PCP

The Association Request and Response frames are used to establish an MMSL cluster between a non-AP and non-PCP MM-SME coordinated STA and an AP or PCP. If the AP or PCP is not an MM-SME coordinated STA, the AP or PCP shall include the MMS element received from the non-AP and non-PCP MM-SME coordinated STA in the Association Response frame sent as response. If the AP or PCP is an MM-SME coordinated STA, the AP or PCP should include its own MMS element that contains its advertised MAC entities in the Association Response frame and shall not include the MMS element received from the non-AP and non-PCP MM-SME coordinated STA in the Association Response frame. The AP or PCP shall not respond with any MMS element if it is not MMSL cluster capable.

The setup of the MMSL cluster fails if the Association Response frame does not contain the MMS element.

11.32.2.3 MMSL cluster setup of non-AP and non-PCP STA with another non-AP and non-PCP STA

If a non-AP and non-PCP MM-SME coordinated STA associated with an AP or PCP has established an AID identified MMSL cluster with the AP or PCP, the non-AP and non-PCP MM-SME coordinated STA shall not use a MAC address that was not included in the MMS element delivered to the AP or PCP to establish an MMSL cluster with another non-AP and non-PCP MM-SME coordinated STA associated with the same AP or PCP.

An ADDTS Request/Response frame exchange with a PTP TSPEC shall be used to establish the MMSL cluster between non-AP and non-PCP MM-SME coordinated STAs and between a non-AP and non-PCP MM-SME coordinated STA and a non-AP and non-PCP non-MM-SME coordinated STA.

A non-AP and non-PCP MM-SME coordinated STA shall include an MMS element that contains its advertised MAC entities in transmitted ADDTS Request frames. If the non-AP and non-PCP STA is not an MM-SME

coordinated STA, the non-AP and non-PCP STA should include the MMS element with the MMS Element Owner field set to "no Owner" in the ADDTS Request frame.

The non-AP and non-PCP MM-SME coordinated STA shall include its own MMS element that contains its advertised MAC entities in transmitted ADDTS Response frames. The non-MM-SME coordinated STA may include the MMS element of the MM-SME coordinated STA from which it received an ADDTS Request frame in the ADDTS Response frame sent as response. The non-MM-SME coordinated STA shall not respond with any MMS element if it is not MMSL cluster capable.

The setup of the MMSL cluster fails if the ADDTS Response frame does not contain the MMS element.

11.33 DMG coexistence with non-IEEE-802.11 systems

This subclause describes the features available in this standard to improve coexistence with other systems that operate in the 60 GHz band, including IEEE 802.15 systems.

The same common channelization that is defined in other specifications for systems that operate in the 60 GHz band is adopted by the DMG PHY specifications (20.3.1 (Channelization) and 28.3.4 (Channelization)) for 2.16 GHz channels. In regulatory domains where 2 or more channels are defined, a DMG STA should support at least 2 channels.

An AP should not start an infrastructure BSS on a channel where the signal level is at or above aDMGDetectionThres or upon detecting a valid IEEE 802.15.3 CMS preamble at a receive level greater than or equal to –60 dBm.

If a DMG STA is capable of performing directional channel measurements (11.30) to detect non-IEEE-Std-802.11 transmissions on a channel, it can report the results of the measurements to the STA's AP or PCP.

If a DMG STA detects a non-IEEE-802.11 transmission on its channel or if the AP or PCP receives a report (11.10) from a DMG STA on a non-IEEE-802.11 transmission, the following mechanisms might be used to mitigate interference:

- Change operating channel (11.8)
- Beamforming (10.41)
- Reduce transmit power (11.7)
- Perform FST (11.31)
- Move the TBTT (11.29.2), and thus the beacon interval, in the case of an AP or PCP
- Change the schedule of SPs and CBAPs in the beacon interval (9.4.2.130) in the case of an AP or PCP
- Defer transmission for a later time
- For periods of time in the beacon interval where the STA experiences poor channel quality, the STA can use the Traffic Scheduling Constraint Set field within the DMG TSPEC element (9.4.2.132) to request its AP or PCP to avoid scheduling an SP for that DMG STA during those periods of time in the beacon interval.
- In an EDMG BSS, when operating over multiple channels, the occupied bandwidth of a PPDU transmitted by a TXOP holder may be smaller than the occupied bandwidth of the last PPDU transmitted by the TXOP holder within the same TXOP (10.6.7.6 (Channel Width selection for Control frames transmitted by EDMG STAs)).
