    DESCRIPTION
       "This is a status variable.
       It is written by the SME when a measurement report is completed.

       This variable indicates the offset of the secondary channel relative to
       the primary channel, equal to 1 if the secondary channel is above the pri-
       mary channel, equal to 3 if the secondary channel is below the primary
       channel, equal to 0 if no secondary channel is present. The value 2 is
       reserved. See 9.4.2.55"

    DESCRIPTION
       "This is a status variable.
       It is written by the SME when a measurement report is completed.

       This variable indicates protection requirements of HT transmissions. Equal
       to 0 if all STAs detected in the primary or the secondary channel or that
       are a member of this BSS are HT STAs and either all STAs that are known by
       the transmitting STA to be a member of this BSS are 20/40 MHz HT in a 20/
       40 MHz BSS or this BSS is a 20 MHz BSS. Equal to 1 (nonmember protection
       mode) if there is at least one non-HT STA detected in either the primary
       or the secondary channel or in both the primary and secondary channels and
       that is not known by the transmitting STA to be a member of this BSS and
       all STAs that are known by the transmitting STA to be a member of this BSS
       are HT STAs. Equal to 2 if all STAs detected in the primary or the second-
       ary channel or that are known by the transmitting STA to be a member of
       this BSS are HT STAs and this BSS is a 20/40 MHz BSS and there is at least
       one 20 MHz HT STA associated with this BSS. Equal to 3 (non-HT mixed mode)
       otherwise. See 9.4.2.54.2"

```
        row creation attempt for dot11WNMRequestTable. If no new rows can be cre-
        ated for some reason, such as memory, processing requirements, etc, the
        SME shall set this attribute to 0. It shall update this attribute to a
        proper value other than 0 as soon as it is capable of receiving new mea-
        surement requests. The nextIndex is not necessarily sequential nor mono-
        tonically increasing."
    ::= { dot11WNMRequest 1 }

dot11WNMRequestTable OBJECT-TYPE
    SYNTAX SEQUENCE OF Dot11WNMRequestEntry
    MAX-ACCESS not-accessible
    STATUS current
    DESCRIPTION
        "This group contains the current list of requests for WNM reports to be
        issued and have been issued until removed. A network manager adds a WNM
        request by creating a row with createAndWait row status and then filling
        in the request parameters/attributes. The request becomes active to be
        issued when the row status is set to Active. The columnar objects or
        attributes other than the rowStatus shall not be written if the rowStatus
        is Active. The request rows can be deleted, if commanded by a network man-
        ager via changing the value of dot11WNMRqstRowStatus to Destroy. This may
        leave orphaned rows if a manager crashes and forgets which rows are being
        used by it. One recommended way to manage orphaned or finished rows is to
        delete rows if their dot11WNMRqstRowStatus remains other than Active for
        longer than a period (recommend at least 5 minutes, IETF RFC 2579). Or
        another recommended way is to delete older rows as needed based on their
        dot11WNMRqstTimeStamp values. This can be done by the agent as well as the
        manager."

    SYNTAX RowStatus
    MAX-ACCESS read-create
    STATUS current
    DESCRIPTION
        "This is a control variable.
        It is written by an external management entity when requesting a measure-
        ment, and by the SME when accepting a management request.

        The Row Status column of the current row, used for tracking status of an
        individual request. When this attribute is set to Active, AND a measure-
        ment request can be unambiguously created based on the parameters in the
        row, then the MLME may proceed to issue the request to its intended tar-
        gets when appropriate. If not, this attribute may be set to Not-ready
        immediately to indicate parametric errors. However, it is the network man-
        agers
        responsibility to correct the error. If the request is successfully issued
        to the target STA, then the rowStatus is set to notInService."

   STATUS current
   DESCRIPTION
      "This is a status variable.
      It is written by the SME when a management report is completed.

      This attribute indicates the value of the STA TSF timer at the time the
      measurement started. In a triggered Multicast Diagnostics report, this is
      the TSF value at the reporting STA when the trigger condition was met.
      When the reason for sending the report is Performance Measurement and the
      Multicast Received MSDU Count is nonzero, the Measurement Time field is
      set to the value of the STA TSF timer at the time of the first group
      addressed MSDU received during the measurement interval."

    MAX-ACCESS read-only
    STATUS current
    DESCRIPTION
        "This is a status variable.
        It is written by the SME when a management report is completed.

        This attribute indicates the twelve least significant bits of the First
        Sequence Number field. When the LSB of the first octet of the Multicast
        MAC address field in the multicast diagnostic request is set to 1, the
        twelve LSBs of the First Sequence Number field contain the sequence number
        of the first frame received with destination address equal to the value in
        the Multicast MAC address field during the measurement period. When the
        LSB of the first octet of the Multicast MAC address field in the multicast
        diagnostic request is set to 0, the twelve LSBs of the First Sequence Num-
        ber field contain the sequence number of the first group addressed frame,
```

dot11WNMMulticastDiagnosticRprtMcstRate OBJECT-TYPE
    SYNTAX Unsigned32 (0..65535)
    UNITS "0.5 Mb/s"
    MAX-ACCESS read-only
    STATUS current
    DESCRIPTION
        "This is a status variable.
        It is written by the SME when a management report is completed.

        This attribute indicates the highest data rate at which the STA has
        received a group addressed frame during the measurement period. The Multi-
        cast Rate field is encoded with the MSB set to 1 to indicate that the data
        rate is in the basic rate set, and set to 0 to indicate that the data rate
        is not in the basic rate set. The remaining 15-bit value is multiplied by
        0.5 Mb/s to indicate the data rate. The Multicast Rate field is set to 0
        by the STA to indicate that it has not received a group addressed frame
        during the measurement period."

```
        This attribute indicates the interval between two successive periods of
        interference. When the interval between two successive periods of inter-
        ference is variable the field is set to 2^32-1. When the interval between
        two successive periods of interference is equal or greater than 2**32-2
        the field is set to 2^32-2. If no colocated interference is present the
        field is set to 0."

    MAX-ACCESS read-only
    STATUS current
    DESCRIPTION
        "This is a status variable.
        It is written by the SME when a management report is completed.

        This attribute contains the least significant 4 octets (i.e., B0-B31) of
        the TSF timer at the start of the interference burst. When either the
        Interference Interval or the Interference Burst Length fields are set to
        2^32-1, this field indicates the average duty cycle. The average duty
        cycle value is defined as Floor((2^32-2) * [average interference burst
        length (microsecond)]/[average interference interval (microsecond)] +
        0.5). When the interference is nonperiodic the Interference Start Time
        field is set to 0. If no colocated interference is present the field is
        set to 0."

    DESCRIPTION
       "This is a control variable.
       It is written by the SME or external management entity.
       In a non-AP STA or mesh STA receiving GCR service, it is written by the
       MAC when it receives a DMS Response frame that contains a DMS Status field
       with a GCR Response subelement and a Response Type subfield set to Accept.
       In an AP or mesh STA providing GCR service, changes take effect for the
       next MLME-START.request primitive.
       In a non-AP STA or mesh STA receiving GCR service, changes take effect as
       soon as practical in the implementation.

       The purpose of dot11GCRConcealmentAddress is to define the group address
       that is used by the GCR procedures (as defined in 11.21.16.3.5) to conceal
       group addressed frames from STAs that do not support GCR."

   DESCRIPTION
      "This is a control variable.
      It is written by an external management entity or the SME.
      Changes take effect as soon as practical in the implementation.

      Datum is an 8-bit value encoding the horizontal and vertical references
      used for the coordinates given in this LCI. IETF RFC 6225 defines the
      values of Datum. Type 1 is WGS-84, the coordinate system used by GPS. Type
      2 is NAD83 with NAVD88 vertical reference. Type 3 is NAD83 with Mean Lower
      Low Water vertical datum. All other types are reserved. This field is
      derived from IETF RFC 6225."

    STATUS current
    DESCRIPTION
       "This is a control variable.
       It is written by an external management entity.
       Changes take effect as soon as practical in the implementation.

       This attribute indicates the number of octets in a PSDU, below which an
       RTS/CTS handshake is not performed if dot11TXOPDurationRTSThreshold is
       1023 or it is not present, except as RTS/CTS is used as a cross modulation
       protection mechanism as defined in 10.27. An RTS/CTS handshake is per-
       formed at the beginning of any frame exchange sequence where the PSDU con-
       tains an MPDU with the Type subfield equal to Data or Management and an
       individual address in the Address 1 field, and the length of the PSDU is
       greater than this threshold. Setting this attribute to be larger than the
       maximum PSDU size has the effect of turning off the RTS/CTS handshake for
       frames of Data or Management type transmitted by this STA. Setting this
       attribute to 0 has the effect of turning on the RTS/CTS handshake for all
       frames of Data or Management type transmitted by this STA."

dot11MUEDCATableCWmin OBJECT-TYPE
   SYNTAX Unsigned32 (0..255)
   MAX-ACCESS read-only
   STATUS current
   DESCRIPTION
      "This is a control variable.
      It is written by the MAC upon receiving an MU EDCA Parameter Set.
      Changes take effect as soon as practical in the implementation.

      This attribute specifies the value of the minimum size of the window that
      is used by a STA for a particular AC for generating a random number for
      the backoff. The value of this attribute is such that it could always be
      expressed in the form of 2**X - 1, where X is an integer. "
   ::= { dot11MUEDCAEntry 2 }

dot11MUEDCATableCWmax OBJECT-TYPE
   SYNTAX Unsigned32 (0..65535)
   MAX-ACCESS read-only
   STATUS current
   DESCRIPTION
      "This is a control variable.
      It is written by the MAC upon receiving an MU EDCA Parameter Set.
      Changes take effect as soon as practical in the implementation.

      This attribute specifies the value of the maximum size of the window that
      is used by a STA for a particular AC for generating a random number for
      the backoff. The value of this attribute is such that it could always be
      expressed in the form of 2**X - 1, where X is an integer."
   ::= { dot11MUEDCAEntry 3 }

dot11MUEDCATableAIFSN OBJECT-TYPE
   SYNTAX Unsigned32 (0..15)
   MAX-ACCESS read-only
   STATUS current
   DESCRIPTION
      "This is a control variable.
      It is written by the MAC upon receiving an MU EDCA Parameter Set element.
      Changes take effect as soon as practical in the implementation.

      This attribute specifies the number of slots, after a SIFS, that the STA,
      for a particular AC, senses the medium idle either before transmitting or
      executing a backoff, except that the value 0 indicates that EDCA is
      disabled for that AC."
   ::= { dot11MUEDCAEntry 4 }

dot11MUEDCATableTimer OBJECT-TYPE
   SYNTAX Unsigned32 (1..255)
   UNITS "8 TUs"
   MAX-ACCESS read-only
   STATUS current
   DESCRIPTION
      "This is a control variable.
      It is written by an external management entity.
      Changes take effect as soon as the STA sends a frame in response to a
      Basic Trigger frame.

      This attribute specifies the duration of time during which the HE STA uses
      the MU EDCA parameters for the corresponding AC."

    STATUS current
    DESCRIPTION
        "This is a capability variable.
        Its value is determined by STA capabilities.

        This attribute is a bitmap that indicates the preamble pruncturing
        support, where bit 0 is set to 1 to indicate support for the reception of
        an 80 MHz preamble where the only punctured subchannel is the secondary 20
        MHz subchannel, bit 1 is set to 1 to indicate support for the reception of
        an 80 MHz preamble where the only punctured subchannel is one of the two
        20 MHz subchannels in the secondary 40 MHz channel, bit 2 is set to 1 to
        indicate support for the reception of a 160 MHz or 80+80 MHz preamble
        where the only punctured subchannels are the secondary 20 MHz channel and
        zero to two of the 20 MHz subchannels in the secondary 80 MHz channel, and
        bit 3 is set to 1 to indicate support for the reception of a 160 MHz or
        80+80 MHz preamble where the only punctured subchannels are zero, one or
        both of the 20 MHz subchannels in the secondary 40 MHz channel and zero to
        two of the 20 MHz subchannels in the secondary 80 MHz channel with at
        least one 20 MHz subchannel punctured. For bits 2 and 3, if two of the 20
        MHz subchannels in the secondary 80 MHz channel are punctured, these are
        either the lower two or the higher two. No more than two adjacent 20 MHz
        subchannels are punctured across a 160 MHz preamble."

```
        It is written by an external management entity or the SME.
        Changes take effect as soon as practical in the implementation.

        This attribute contains the national subdivisions (state, Region,
        province, prefecture). Example: California. The A1 element is used for the
        top level subdivision within a country. In the absence of a country-
        specific guide on how to use the A-series of elements, the second part of
        the ISO 3166-2 code for a country subdivision SHOULD be used. The ISO
        3166-2 code is a formed of a country code and hyphen plus a code of one,
        two or three characters or numerals. For the A1 element, the leading
        country code and hyphen are omitted and only the subdivision code is
        included.

        For example, the codes for Canada include CA-BC, CA-ON, CA-QC; Luxembourg
        has just three single character codes: LU-D, LU-G And LU-L; Australia uses
        both two and three character codes: AU-ACT, AU-NSW, AU-NT; France uses
        numeric codes for mainland France and letters for territories: FR-75, FR-
        NC."

Annex D

(normative)

Regulatory references

D.1 External regulatory references

This annex and Annex E provide information and specifications for operation in many regulatory domains.

WLANs implemented in accordance with this standard and the specifications and definitions referenced in it are subject to equipment certification and operating requirements established by regional and national regulatory administrations. The specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regional and national regulations are subject to revision or may be superseded. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Table D-1 for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

The documents listed in Table D-1 specify current regulatory requirements for various frequency bands and geographic areas at the time this standard was developed. They are provided for information only and are subject to change or revision at any time.

Table D-1—Regulatory requirement list

Geographic area	Approval standards	Documents	Approval authority
Australia	Federal Register of Legislative Instruments	Radiocommunications (Low Interference Potential Devices) Class Licence 2000, Sections 132 and 135	FRLI
Canada	Minister of Industry	RSS-210 — License-exempt Radio Apparatus (All Frequency Bands): Category I Equipment	Industry Canada
China	Ministry of Industry and Information Technology (MIIT)	Xin Bu Wu [2002] #353, Xin Bu Wu [2002] #277, Gong Xin Bu Wu Han [2012] #620, MIIT Wireless [2005] 423	MIIT
Europe	European Conference of Postal and Telecommunications (CEPT) Administrations and its Electronic Communications Committee (ECC). Also, European Radiocommunications Office, European Telecommunications Standards Institute (ETSI)	ECC DEC (04) 08, ETSI EN 300 328 [B10], ETSI EN 301 893, ETSI ES 202 663 [B12], ETSI EN 302 571 [B11], Clause 5, ERC Recommendation 70-03 [B8]	CEPT
Japan	Ministry of Internal Affairs and Communications (MIC)	MIC Equipment Ordinance (EO) for Regulating Radio Equipment Articles 7, 49.20, 49.21[a], 49.14, 54.5	MIC
New Zealand	Radio Spectrum Management	Section 111 of Radiocommunications Act 1989, Regulation 9 of Radiocommunications Regulations 2001	Ministry of Economic Development

Table D-1—Regulatory requirement list *(continued)*

Geographic area	Approval standards	Documents	Approval authority
United States and its territories	Federal Communications Commission (FCC)	47 CFR [B6], Part 15, Sections 15.205, 15.209, 15.247 and 15.255; and Subpart E, Sections 15.401–15.407, and Subpart H, Sections 15.701–15.716, Section 90.210, Sections 90.371–383, Sections 90.1201–90.1217, Sections 90.1301–90.1337, Section 95.639, Sections 95.1501–1511 First Report and Order, 35 FCC Rcd. 13440 (15)[b]	FCC
Singapore	Infocomm Development Authority of Singapore	IDA TS SRD 2011 Technical Specification for Short Range Devices	IDA
South Korea	Ministry of Science, ICT and Future Planning / Radio Research Agency (MSIP RRA) Public Regulations Announcement	Doc. No. 2012-101 “Wireless Facilities”	MSIP RRA

[a] Frequency planning for licensed STAs in Japan is performed by the regulatory authority and the licensees, addressing the coexistence among STAs operating with a variety of air propagation times and the coexistence between STAs using 20 MHz channel spacing, STAs operating with 10 MHz channel spacing, and STAs operating with 5 MHz channel spacing. Note also the CCA mechanism is preserved in licensed operation.
[b] The FCC adopted on 18 November 2020 a First Report and Order to make the 5.9 GHz band’s lower 45 MHz available for unlicensed operations.

Behavior limits are listed in Table D-2.

Table D-2—Behavior limits

Behavior limit	Description
NomadicBehavior	The location of the station may change but is stationary while in use. The nomadic use EIRP power limits apply if the country allows more than one transmit power limit in the band. This behavior is specified only in bands where behavior 10 License Exempt bands is also allowed.
LicenseExemptBehavior	Frequency bands where some fixed stations can be operated without a license at a higher radiated transmit power than permitted for nomadic use. This behavior is specified only in bands where behavior 1 nomadic use is also allowed.
PrimaryChannelLowerBehavior[a]	20/40 MHz BSS primary channel with secondary channel above the primary channel or 20 MHz BSS primary channel operated by a 40MC HT AP and also 20 MHz operational channel for a non-AP STA when the non-AP STA is associated with a 40MC HT AP. See NOTE 1.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table D-2—Behavior limits *(continued)*

Behavior limit	Description
PrimaryChannelUpperBehavior[a]	14 20/40 MHz BSS primary channel with secondary channel below the primary channel or 20 MHz BSS primary channel operated by a 40MC HT AP and also 20 MHz operational channel for a non-AP STA when the non-AP STA is associated with a 40MC HT AP. See NOTE 1.
CCA-OCSEDBehavior[b]	The PHY shall also indicate a medium busy condition when CCA-Operating Class Specific Energy Detect detects a channel busy condition.
DFS_50_100_Behavior	A station operating in a band where radiolocation radar is primary, and station operation has in-service monitoring requirements for 50-100 μs radar pulses.
ITS_nonmobile_operations	Operations related to an ITS station operating at a fixed location registered with regulatory authorities, e.g., a Dedicated Short Range Communication Services (DSRCS) Roadside Unit (RSU).
ITS_mobile_operations	Operations related to an ITS mobile station, e.g., a vehicle's DSRCS On-board Unit (OBU).
80+	In a channel width that contains two or more frequency segments, the frequency segment that does not contain the primary 80 MHz channel (see NOTE 2)
UseEirpForVHTTxPowEnv	A STA that sends one or more Transmit Power Envelope elements shall indicate EIRP in the Local Maximum Transmit Power Unit Interpretation subfield in one of the Transmit Power Envelope elements
GeoDB	A STA operating in a TVWS band where broadcast TV operation is primary and STA operation has GDB requirements. When operating in TVWS, channel numbers are as assigned in regulation.
DSSSonly	A STA operating in a band where modulation is restricted to the DSSS PHY or HR/DSSS PHY as described in Clause 15 and Clause 16, respectively.
NOTE 1—The fields that specify the 40 MHz channels are described in 19.3.15.4. NOTE 2—The maximum number of frequency segments is PHY dependent.	

[a] For 20 MHz operation where the operating class signifies 40 MHz channel spacing, the 20 MHz channel corresponds to the channel number indicated.
[b] Procedures that may be used to improve sharing spectrum in addition to explicit regulatory requirements.

D.2 Radio performance specifications

D.2.1 Transmit and receive in-band and out-of-band spurious emissions

Spurious transmissions shall comply with national regulations.

D.2.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

The maximum allowable STA transmit power classifications for ITS nonmobile operations in the United States and its territories 5.85–5.925 GHz band are shown in Table D-3.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table D-3—Maximum STA transmit power classification for the 5.85–5.925 GHz band in the United States and its territories

STA transmit power classification	Maximum STA transmit power (mW)	Maximum permitted EIRP (dBm)
A	1	23
B	10	23
C	100	33
D	760 Note that for this class higher power is permitted as long as the power level is reduced to this level at the antenna connector and the emission mask specifications are met.	33 for nongovernment 44.8 for government

The maximum allowed transmit power and maximum bandwidth (BW) limits for an S1G STA are shown by country in Table D-4.

Table D-4—Maximum STA transmit power and maximum BW allowed for the S1G band

Geographic area	Frequency (MHz)	Maximum BW allowed (MHz)	Maximum STA transmit power (Max EIRP (mW) except where noted)
Australia	915–928	8	See NOTE 1
Europe	863–868	1	See NOTE 5
	917.4–919.4		
Japan	915.9–916.9	1	See NOTE 6
	920.5–929.7	4	See NOTE 2
	920.5–923.5	1	See NOTE 3
New Zealand	915–928	8	See NOTE 4
United States and its territories	902–928	Not defined	1000
Singapore	866–869, 920–925	4	500
South Korea	917–923.5	Not defined	3, 10

NOTE 1—Max EIRP ≤ 30 dBm and PSD ≤ 25 mW/3 kHz

NOTE 2—1 or 20 mW transmitter output power plus up to 3 dBi antenna gain (maximum EIRP is 1 or 20 mW + 3 dBi)

NOTE 3—250 mW transmitter output power plus up to 3 dBi antenna gain (maximum EIRP is 250 mW + 3 dBi)

NOTE 4—Max EIRP ≤ 5 dBm (915 MHz to 928 MHz) for general sensor-type devices and Max EIRP ≤ 36 dBm (921.5 MHz to 928 MHz) for digital modulation transmitters

NOTE 5—Maximum effective radiated power ≤ 25 mW

NOTE 6—1 mW transmitter output power plus up to 3 dBi antenna gain (maximum EIRP is 1 mW + 3 dBi)

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

D.2.3 Transmit spectrum mask

Transmit spectrum masks defined in regulation are subject to change or revision at any time.

For operation in the 5.85–5.925 GHz band the transmitted spectrum shall be as follows:

a) For any STA using 5 MHz channel spacing, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 4.5 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-5 for the transmit power class of the STA.

b) For any STA using 10 MHz channel spacing, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 9 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-6 for the transmit power class of the STA.

c) For any STA using 20 MHz channel spacing and transmitting a PPDU that is not a 20 MHz NGV PPDU or 20 MHz non-NGV duplicate PPDU, the transmitted spectral density shall have a 0 dBr bandwidth not exceeding 18 MHz and shall not exceed the spectrum mask created using the permitted power spectral density levels listed in Table D-7 for the transmit power class of the STA.

NOTE—The conditions under which conformance to transmit spectral mask C2 is required are specified in 32.3.11.1.

Table D-5—Spectrum mask data for 5 MHz channel spacing

STA transmit power class	Permitted power spectral density, dBr				
	± 2.25 MHz offset (±f1)	± 2.5 MHz offset (±f2)	± 2.75 MHz offset (±f3)	±5 MHz offset (±f4)	± 7.5 MHz offset (±f5)
Class A	0	–10	–20	–28	–40
Class B	0	–16	–20	–28	–40
Class C	0	–26	–32	–40	–50
Class D	0	–35	–45	–55	–65

Table D-6—Spectrum mask data for 10 MHz channel spacing

STA transmit power class	Permitted power spectral density, dBr				
	± 4.5 MHz offset (±f1)	± 5.0 MHz offset (±f2)	± 5.5 MHz offset (±f3)	± 10 MHz offset (±f4)	± 15 MHz offset (±f5)
Class A	0	–10	–20	–28	–40
Class B	0	–16	–20	–28	–40
Class C	0	–26	–32	–40	–50
Class D	0	–35	–45	–55	–65

Table D-7—Spectrum mask data for 20 MHz channel spacing

STA transmit power class	Permitted power spectral density, dBr				
	± 9 MHz offset (±f1)	± 10.0 MHz offset (±f2)	± 11 MHz offset (±f3)	± 20 MHz offset (±f4)	± 30 MHz offset (±f5)
Class A	0	–10	–20	–28	–40
Class B	0	–16	–20	–28	–40
Class C	0	–26	–32	–40	–50
Class D	0	–35	–45	–55	–65

The transmit spectral mask is created and applied as shown in Figure D-1 about the channel center frequency (Fc) defined by the channel starting frequency and channel number from the operating class. The 0 dBr level is the maximum power spectral density measured in the channel. The measurements of transmit spectral density are made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

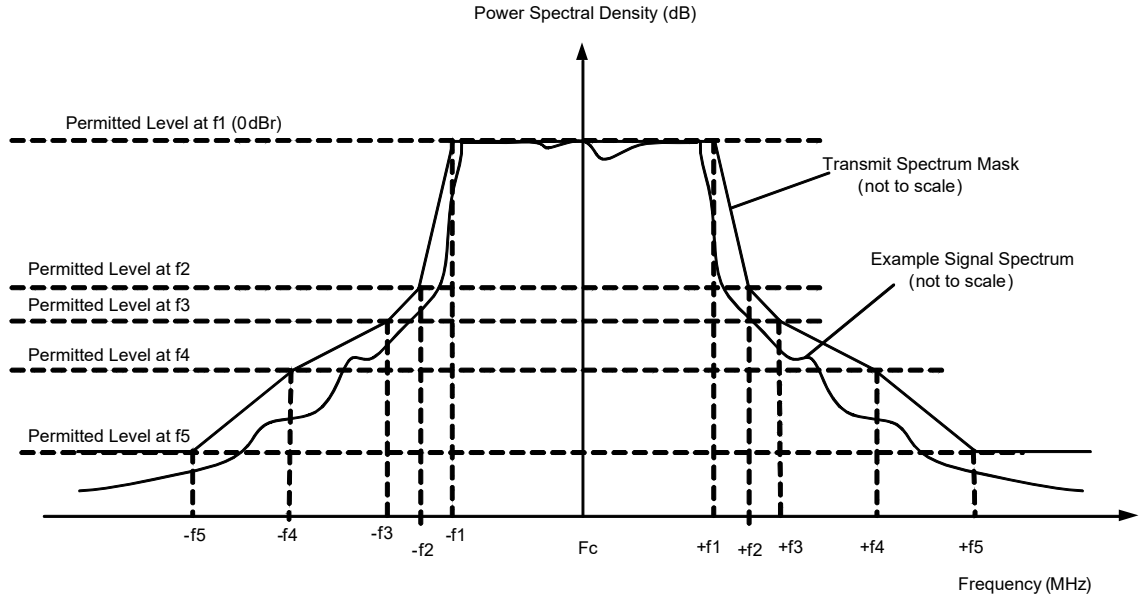

Figure D-1—Transmit spectrum mask and application

D.2.4 Transmit Mask M

This subclause defines the characteristics of transmit mask M.

The power spectral density of the emissions shall be attenuated below the output power of the transmitter as follows:

a) On any frequency removed from the center frequency between 0% and 45% of the channel bandwidth (BW): 0 dB.

b) On any frequency removed from the center frequency between 45% and 50% of the channel bandwidth: 568 log10 (% of (BW)/45) dB.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

c) On any frequency removed from the center frequency between 50% and 55% of the channel bandwidth: 26 + 145 log10 (% of BW/50) dB.

d) On any frequency removed from the center frequency between 55% and 100% of the channel bandwidth: 32 + 31 log10 (% of (BW)/55) dB.

e) On any frequency removed from the center frequency between 100% and 150% of the channel bandwidth: 40 + 57 log10 (% of (BW)/100) dB.

f) On any frequency removed from the center frequency between above 150% of the channel bandwidth: 50 dB or 55 + 10 log10 (P) dB, whichever is the lesser attenuation.

g) The 0 dB reference is measured relative to the highest average power of the fundamental emission measured across the designated channel bandwidth using a resolution bandwidth of 100 kHz and a video bandwidth of 30 kHz. The power spectral density is the power measured within the resolution bandwidth of the measurement device divided by the resolution bandwidth of the measurement device. Emission levels are also based on the use of measurement instrumentation employing a resolution bandwidth of at least one percent of the occupied bandwidth.

D.2.5 CCA-OCSED threshold

CCA-OCSED thresholds for operation in specific bands are given in E.2.

Annex E

(normative)

Country elements and operating classes

E.1 Country information and operating classes

WLANs implemented in accordance with this standard and the specifications and definitions referenced in it may be subject to equipment certification and operating requirements established by regional and national regulatory administrations. The specification establishes minimum technical requirements for interoperability, taking into consideration established regulations at the time this standard was issued. These regional and national regulations may be revised or may be superseded. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Table D-1 and their successors for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

The Country element (see 9.4.2.7) allows a STA to configure its PHY and MAC for operation when the Operating Triplet field is present. The Operating Triplet field indicates both PHY and MAC configuration characteristics and operational characteristics. The First Channel Number field of subsequent Subband Triplet fields is based on the dot11ChannelStartingFactor that is indicated by the Operating Class field.

The operating class value is an index into sets of values for radio operation in a regulatory domain. An operating class value indicates:

- The frequencies corresponding to channel numbers (they are defined in PHY clauses)
- The channel center frequencies that may be used (they are defined in PHY clauses)
- The maximum channel width that may be used
- Behavioral constraints listed in Table D-2

The channel starting frequency variable is a frequency, used together with an operating class number and a channel number, to calculate a channel center frequency. A "—" in the Channel starting frequency column of the operating classes tables (Table E-1 to Table E-6) indicates the channel starting frequency is not defined by the operating class and is derived from regulation.

Channel spacing is the frequency difference between nonoverlapping adjacent channel center frequencies when using the maximum bandwidth of one frequency segment allowed for this operating class.

The channel set is the list of integer channel numbers that are legal for a regulatory domain and class. A "—" in the Channel set column of the operating classes tables (Table E-1 to Table E-6) indicates either that the values in the channel number of the center frequency field apply for calculating channel center frequencies of this operating class, or where both the channel set field and the channel number of the center frequency field are "—" indicates that the channel set is not defined by the operating class and is derived from regulation. It is not required that a station supports operation on any of the channels in the channel set.

The channel number of the center frequency is the set of integer channel numbers that correspond to frequency segments and that are allowed for the operating class. A"—" in the channel number of the center frequency column of the operating classes tables (Table E-1 to Table E-6) indicates either that the values in the channel set field apply for calculating channel center frequencies of this operating class or, when both the Channel set and the channel number of the center frequency column of the operating classes tables

(Table E-1 to Table E-6) are "—", indicates that the channel number of the center frequency is not defined by the operating class and is derived from regulation.

A behavior limits set is an enumerated list, each element of which points to a row in Table D-2 containing behavior limits in various regulatory domains.

Operating classes for operation in the United States and its territories are enumerated in Table E-1.

Table E-1—Operating classes in the United States and its territories

Operating class	Global operating class (see Table E-4)	Channel starting frequency (GHz)	Channel spacing (MHz)	LC IF Channel starting frequency (MHz)	Channel set	Channel number of the center frequency	Behavior limits set
1	115	5	20	–154	36, 40, 44, 48	—	Applicable to LC

131–255	Reserved	Reserved	Reserved		Reserved	Reserved	Reserved

NOTE 1—The channel spacing for operating classes 22 to 33 specifies the maximum radio bandwidth of one frequency segment. In these operating classes, the AP operating in a 20/40 MHz BSS, and the operating channel width for a non-AP STA is either 20 MHz or 40 MHz.

NOTE 2—The channel spacing for operating classes 128, 129, and 130 specifies the maximum radio bandwidth of one frequency segment.

[a] This operating class specifies a list of channels in the 5.9 GHz band. Current regulations might permit only a subset of these channels.

[b] It is the responsibility of management layers outside the scope of this standard to ensure that channels in use at any location are nonoverlapping.

Operating classes for operation in Europe are enumerated in Table E-2.

Table E-2—Operating classes in Europe

Operating class	Global operating class (see Table E-4)	Channel starting frequency (GHz)	Channel spacing (MHz)	LC IF Channel starting frequency (MHz)	Channel set	Channel number of the center frequency	Behavior limits set

NOTE 2—The channel spacing for operating classes 128, 129, and 130 specifies the maximum radio bandwidth of one frequency segment.

[a] The use of channels 34, 38, 42, and 46 was included in the initial 5 GHz rules in May, 2005 and cannot be used after May 2012.

Operating classes for operation anywhere in the world are enumerated in Table E-4, and are used in addition to the operating classes enumerated in Table E-1, Table E-2, Table E-3, Table E-5, and Table E-6 (see 9.4.2.52). Where a BSS includes STAs that do not support global operating classes, then all requests and Action frames to those STAs that convey elements containing operating classes shall use nonglobal operating class values.

Table E-4—Global operating classes

Operating class	Nonglobal operating class(es) (see NOTE 3)	Channel starting frequency (GHz)	Channel spacing (MHz)	LC IF Channel starting frequency (MHz)	Channel set	Channel number of the center frequency	Behavior limits set

Table E-4—Global operating classes *(continued)*

Operating class	Nonglobal operating class(es) (see NOTE 3)	Channel starting frequency (GHz)	Channel spacing (MHz)	LC IF Channel starting frequency (MHz)	Channel set	Channel number of the center frequency	Behavior limits set
192–254	—	Vendor specific	Vendor specific		Vendor specific	—	Vendor specific
255	—	Reserved	Reserved		Reserved	—	Reserved

NOTE 1—The channel spacing for operating classes 116, 117, 119, 120, 122, 123, 126, and 127 specifies the maximum radio bandwidth of one frequency segment In these operating classes, the AP operates in a 20/40 MHz BSS, and the operating channel width for a non-AP STA is either 20 MHz or 40 MHz.

NOTE 2—The channel spacing for operating classes 128, 129, and 130 specifies the maximum radio bandwidth of one frequency segment.

NOTE 3—E-x-y refers to operating class y in Table E-x.

For Behavior limit GeoDB, the channel starting frequency shall be the frequency that results in the regulatory domain's channel number being the RLAN channel number.

S1G operating classes are enumerated in Table E-5. Definition of type 1 and type 2 channels for CCA Level Classification and required behavior is described in #23.3.18.5.3 and 23.3.18.5.4.

Table E-5—S1G operating classes

16–127	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
128	128	5	80	—	42, 58, 155	UseEirpForVHTTxPowEnv
129	129	5	160	—	50	UseEirpForVHTTxPowEnv
130	130	5	80	—	42, 58, 155	80+ UseEirpForVHTTxPowEnv
131–255	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved

NOTE 1—The channel spacing for operating classes 4 to 6 specifies the maximum radio bandwidth of one frequency segment In these operating classes, the AP operates in a 20/40 MHz BSS, and the operating channel width for a non-AP STA is either 20 MHz or 40 MHz.

NOTE 2—The channel spacing for operating classes 128, 129, and 130 specifies the maximum radio bandwidth of one frequency segment.

Nonglobal operating classes refer to the operating classes enumerated in the leftmost column of Table E-1, Table E-2, Table E-3, and Table E-6 (see 9.4.2.52).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 1—The following example Country element (see Figure 9-224) describes U.S. operation (55, 53) using both Table E-1 class 12 (nonglobal) and Table E-4 class 81 (global) for the 2.4 GHz band, 11 channels at 20 dBm limit (in hexadecimal): 07, 0F, 55, 53, 04, C9, 0C, 00, 01, 0B, 14, C9, 51, 0, 01, 0B, 14.

NOTE 2—The following example Country element describes U.S. operation for an 80+80 MHz BSS using Table E-4 classes 116, 128 and 130 at a 100 mW limit for 40 MHz. The contents (in decimal) are 7 [Country element ID], 18 [Length], 85, 83, 4 [Country string indicating the United States and Table E-4], 201, 116, 0 [Operating Triplet field for 20/40 MHz with the primary 20 MHz channel on the lower 20 MHz], 36, 1, 20 [Subband triplet field indicating 20 dBm on the 40 MHz channel 36+40], 201, 128, 0 [Operating Triplet field for 80 MHz], 201, 130, 0, 201, 128, 0 [Pair of Operating Triplet field indicating 80+80 MHz]. Although the Operating Triplet fields for 80 MHz and 80+80 MHz only express BSS bandwidths rather than specific regulatory permissions (so are optional), they are included in this example.

Vendor Specific operating classes are used to carry information not defined in this standard within a single defined format, so that reserved operating classes are not usurped for nonstandard purposes and so that interoperability is more easily achieved in the presence of nonstandard information.

E.2 Band-specific operating requirements

E.2.1 General

E.2 contains requirements specific to particular bands and regulatory domains.

E.2.2 3650–3700 MHz band in the United States and its territories

FCC Part 96 rules for operation in the 3550–3700 MHz frequency band are in force, and operating in the 3650–3700 MHz band under Part 90 Subpart Z rules [B7] ends May 2020. The following text in this subclause contains requirements for operation under Part 90 Subpart Z rules.

The registration authority is the FCC's Universal Licensing System (ULS).

Regulations specify the following:

— Certified mobile and portable STAs do not need to be registered, but they "must" operate under the control of an enabling STA (using DSE procedures).
— A registered STA "must" be a fixed STA.
— A registered STA "must" not operate as an enabling STA until the licensee has registered it as a "base station" in ULS.

Enabling STAs and fixed STAs are registered STAs. Dependent non-AP STAs and dependent APs are dependent STAs.

A STA shall use the following:

— CCA-OCSED
— CS/CCA
— TPC
— DFS

For OFDM PHY operation in this specific band, the CCA-OCSED thresholds shall be less than or equal to –72 dBm for 20 MHz channel widths, –75 dBm for 10 MHz channel widths, and –78 dBm for 5 MHz channel widths (minimum sensitivity for BPSK, R=1/2 + 10 dB in Table 17-21).

No STA shall use channel switch announcement.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

No station may transmit for more than 4 ms without carrier sensing, whether transmitting fragments or frames, unless it is controlled by another STA.

A STA shall have the following equal to true:

— dot11LCIDSERequired
— dot11SpectrumManagementRequired
— dot11MultiDomainCapabilityActivated
— dot11ExtendedChannelSwitchActivated

A STA shall support receiving all channels associated with operating classes 13–15.

A STA shall support transmitting on all channels associated with operating class 15.

A STA shall set the value of dot11DSETransmitDivisor to 256 and the other dot11DSE timer values as shown in Table E-7.

Table E-7—DSE timer limits

Parameter	Seconds
dot11DSEEnablementTimeLimit	32
dot11DSEEnablementFailHoldTime	512
dot11DSERenewalTime	60

E.2.3 5.9 GHz band in the United States and its territories (5.850–5.925 GHz)

STAs operating with a behavior limit of ITS_nonmobile_operations in Table D-2 are required to be registered with the FCC ULS. The registration includes the following:

— Classification by coverage size, which is defined by EIRP, and
— Identification of channels the STA is permitted to use.

A STA shall be classified for operation in this band by their maximum transmit power capability, as listed in Table D-3 in D.2.2. A STA shall be compliant with the spectral emission requirements for their class listed in D.2.3.

A STA shall have dot11OCBActivated equal to true.

EPD as defined in IEEE Std 802 shall be used for transmission of all MSDUs.

E.2.4 5.9 GHz band in Europe (5.855–5.925 GHz)

A STA shall have dot11OCBActivated equal to true.

EPD as defined in IEEE Std 802 shall be used for transmission of all MSDUs.

E.2.5 TVWS band in the United States and its territories and Canada (54–698 MHz)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Each GDD enabling STA and AP in TVWS determines the available TV channels at its location using its own geographic location identification and TV bands database access capabilities. Each GDD dependent STA in TVWS receives an available TV channel list from the STA that enables its operation.

The registration authorities are FCC designated TV bands administrators (FCC 47 CFR [B6], sections 15.713–715).

NOTE 1—IEEE 802.11 terms differ from FCC 47 CFR [B6], section 15.703, in many particulars. However, generally, a GDD enabling STA is Fixed or Mode II TVBD, and each GDD dependent STA has only one GDD enabling STA at any time. Generally, GDD dependent STAs are Mode I TVBDs. Each Fixed or Mode II TVBD is required to contact an authorized TV bands device database and operate based on the information received from that TV bands database. Fixed and Mode II TVBDs are certified to operate with specific TV bands databases using protocols specified by TV bands database administrators. FCC regulations require an encrypted Contact Verification Signal be received by Mode I TVBD to verify the integrity of the list of available channels FCC 47 CFR, section 15.711. Canadian regulation RSS-196 allows Remote Rural Broadband operation at transmit powers to 125 W in 6 MHz. The Canadian Minister of Industry held a consultation documented in SMSE-012-12, wherein a decision to act in concert with FCC license-exempt low power regulations was taken. It is expected that Canadian RSS-210 will be revised to align with FCC 47 CFR, Part 15, Subpart H-Television Band Devices.

STAs operating in TVWS shall use

— CS/CCA
— DFS

No STA operating in TVWS shall use Channel Switch Announcement.

STAs operating in TVWS shall have the following equal to true

— dot11GDDActivated
— dot11OperatingClassesRequired
— dot11SpectrumManagementRequired
— dot11MultiDomainCapabilityActivated
— dot11ContactVerificationSignalActivated

For GDD dependent STA operation in TVWS, the GDD enabling signal (see 11.42.2) is received directly from a GDD enabling STA and is a Beacon frame or Probe Response frame containing a Geodatabase Inband Enabling Signal field indicating that enablement in the frequency band is possible.

All GDD dependent STAs shall set dot11GDD timer values as shown in Table E-8, unless otherwise mandated by regulatory authorities.

Table E-8—TVWS GDD timer limits

Parameter	Seconds
dot11GDDEnablementTimeLimit	32
dot11GDDEnablementFailHoldTime	512
dot11ContactVerificationSignalInterval	60

NOTE 2—Be aware that most protocols above the MAC operate in the opposite endianness from what is used in Table E-9 and Table E-10.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The Device Identification Information format is shown in Table E-9. US is to be understood as also including the United States' territories

Table E-9—Device Identification Information Value fields

Name	Type	Length (octets)	Value	Scope/ Country code
FCC ID	4	14	The device identification contains the 14-octet FCC ID of the device.	US
Industry Canada ID	5	11	The device identification contains the 11-octet Industry Canada ID of the device. .	CA
Device Serial Number	6	4	The Device Serial Number field contains the manufacturer's serial number. This field is present only if the Device Class field (Table 9-419) is equal to 2 (GDD AP) or 3 (GDD fixed STA); otherwise, this field is not present.	US

The WSM Information Value fields format is shown in Table E-10. In some regulatory domains, an AP can retrieve the WSM information from the GDB through the upper layer protocol (e.g., IETF RFC 7545 [B53]). When the AP retrieves the WSM information from the upper layer, it may translate it to the WSM Information field format shown in Table E-10, which is the link-layer-specific information. US is to be understood as also including the United States' territories

Table E-10—WSM Information Value fields

Name	Length (octets)	Value	Scope/ Country code
Device Class	1	Single octet TLV comprising fields in Table 9-419.	WSM
Map ID	1	Bit 0: The Type bit, which indicates whether the following channel list is a full channel list or a partial channel list. If the Type bit is 1, the following channel list is a full channel list; and if the Type bit is 0, the following channel list is a partial channel list. Bits 1–7: The Map version field, which identifies the version of the WSM.	WSM
Channel Number	1	The Channel Number field is a positive integer value as defined in E.1 that indicates the available TV channel for WLAN operation. When the Channel Number field and Maximum Power Level field pairs are repeated, they are listed in ascending TV channel order.	WSM, US
Maximum Power Level	1	The Maximum Power Level field indicates the maximum power, in units of 0.5 dBm, allowed to be transmitted on the channel indicated in the Channel Number field.	WSM, US

NOTE 3—In the United States and its territories, an example for a GDD non-AP STA describing two available channels with power limits of 100 mW and 40 mW is shown as 85, 0x06, 0x00, 0x03, 0x15, 0x28, 0x33, 0x20. Type is 85, length is 0x06, device class is 0x00, a full map with version 1 is 0x03, TV channel 21 is 0x15, 20 dBm maximum power level is 0x28, TV channel 51 is 0x33, 16 dBm maximum power level is 0x20.

E.2.6 TVWS band in Europe

Each GDD enabling STA and AP in TVWS determines the available TV channels at its location using its own geographic location identification and TV bands database access capabilities. Each GDD dependent STA in TVWS receives an available TV channel list from the STA that enables its operation.

The Harmonized Standard for unlicensed device operation in TVWS is EN 301 598.

STAs operating in TVWS shall use:

— CS/CCA
— DFS

No STA operating in TVWS shall use Channel Switch Announcement.

STAs operating in TVWS shall have the following equal to true

— dot11GDDActivated
— dot11OperatingClassesRequired
— dot11SpectrumManagementRequired
— dot11MultiDomainCapabilityActivated
— dot11ContactVerificationSignalActivated

For GDD dependent STA operation in TVWS, the GDD enabling signal (see 11.42.2) is received directly from a GDD enabling STA and is a Beacon frame or Probe Response frame containing a Geodatabase Inband Enabling Signal field indicating that enablement in the frequency band is possible.

All GDD dependent STAs shall set dot11GDD timer values as shown in Table E-11, unless otherwise mandated by regulatory authorities.

Table E-11—TVWS GDD timer limits

Parameter	Seconds
dot11GDDEnablementTimeLimit	32
dot11GDDEnablementFailHoldTime	512
dot11ContactVerificationSignalInterval	60

E.2.7 6 GHz band

When operating in the 6 GHz band, Table E-4 is used for the operating classes, so the third octet of the dot11CountryString is 4. For example, when operating in the 6 GHz band in the United States, the Country String field in the Country element is set to (in hexadecimal) 0x55, 0x53, 0x04.

NOTE 1—The first two octets indicate the United States. The third octet indicates that Table E-4 is in use (see Annex C).

The Regulatory Info subfield in the Control field of the 6 GHz Operation Information field of the HE Operation element expresses the current operational mode of the AP and is interpreted by non-AP STAs with dot11ExtendedRegInfoSupport not set to true as shown in Table E-12, and is interpreted by non-AP

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

STAs with dott11ExtendedRegInfoSupport set to true as shown in Table E-13 when operating in the 6 GHz band.

NOTE 2—Non-AP STAs with dott11ExtendedRegInfoSupport not set to true parse B3 to B5 of the Control field as the Regulatory Info subfield, and ignore B6 of the Control field.

Each regulatory domain might have additional regulations for each Regulatory Info subfield value. Operation in such regulatory domains is subject to the additional regulations. If a non-AP STA is unable to interpret the value of the Regulatory Info field, it might still, in accordance with local regulations, be able to determine a regulatory maximum transmit power to connect to the AP using received Transmit Power Envelope element(s) and/or local sources (see 11.7.5).

Some values defined in Table E-12 and Table E-13 might not be valid in all regulatory domains. If a certain Regulatory Info subfield encoding value is not valid in a regulatory domain, then the value is not used when operating in that regulatory domain.

Table E-12—Regulatory Info subfield interpretation by non-AP STAs with dot11ExtendedRegInfoSupport not set to true

Value	Description
0 or 8	Indoor AP An AP whose operation does not require control from an external system such as an Automated Frequency Coordination (AFC) system but operates under regulatory rules requiring indoor operation, and is subject to additional regulatory requirements intended to prohibit outdoor operation.
1 or 9	Standard power AP An AP whose operation requires control from an external system such as an AFC system.
2 or 10	Very low power AP An AP whose operation does not require control from an external system such as an AFC system, is not subject to additional regulatory requirements intended to prohibit outdoor operation, and is restricted to very low transmit power. NOTE—A 6 GHz non-AP STA conformant with an amendment to a previous revision of this standard might not be able to interpret these values.
3 or 11	Indoor enabled AP An AP whose operation relies on being able to successfully receive an enabling signal (as defined by the regulatory rules) from an indoor AP or an indoor standard power AP. NOTE—A 6 GHz non-AP STA conformant with an amendment to a previous revision of this standard might not be able to interpret these values.
4 or 12	Indoor standard power AP (deprecated) An AP whose operation requires control from an external system such as an AFC system and that is subject to additional regulatory requirements intended to prohibit outdoor operation. NOTE—A 6 GHz non-AP STA conformant with an amendment to a previous revision of this standard might not be able to interpret these values.

Copyright © 2025 IEEE. All rights reserved.

Table E-12—Regulatory Info subfield interpretation by non-AP STAs with dot11ExtendedRegInfoSupport not set to true *(continued)*

Value	Description
5 or 13	Reserved
6 or 14	Reserved
7 or 15	AP role not relevant. An AP whose operation does not affect the regulated behavior of associated or enabled devices. NOTE 1—For instance, the transmission of Transmit Power Envelope elements by the AP might suffice. NOTE 2—A 6 GHz non-AP STA conformant with an amendment to a previous revision of this standard might not be able to interpret these values.

Table E-13—Regulatory Info subfield interpretation by non-AP STAs with dot11ExtendedRegInfoSupport set to true

Value	Description
0	Indoor AP An AP whose operation does not require control from an external system such as an Automated Frequency Coordination (AFC) system but operates under regulatory rules requiring indoor operation, and is subject to additional regulatory requirements intended to prohibit outdoor operation.
1	Standard power AP An AP whose operation requires control from an external system such as an AFC systems.
2	Very low power AP An AP whose operation does not require control from an external system such as an AFC system, is not subject to additional regulatory requirements intended to prohibit outdoor operation, and is restricted to very low transmit power.
3	Indoor enabled AP An AP whose operation relies on being able to successfully receive an enabling signal (as defined by the regulatory rules) from an indoor AP or an indoor standard power AP.
4–6	Reserved

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table E-13—Regulatory Info subfield interpretation by non-AP STAs with dot11ExtendedRegInfoSupport set to true *(continued)*

Value	Description
7	AP role not relevant An AP whose operation does not affect the regulated behavior of associated or enabled devices. NOTE—For instance, the transmission of Transmit Power Envelope elements by the AP might suffice.
8	Indoor standard power AP An AP whose operation requires control from an external system such as an AFC system and also operates under regulatory rules requiring indoor operation, and is subject to additional regulatory requirements intended to prohibit outdoor operation.
9–15	Reserved

In Table E-12 and Table E-13, a WLAN STA is not an external system.
NOTE 3—For example, an indoor enabled AP is not a standard power AP because the indoor AP or the indoor standard power AP (from which the indoor enabled AP receives the enabling signal) are not external systems.

The values 8 (indoor standard power AP) for the Regulatory Info subfield are used instead of the value 0 (indoor AP) when the transmit power for all or part of the indoor AP's BSS bandwidth is controlled by an external system such as an AFC system.

A *fixed client device* is a non-AP STA that operates only on channels provided by an external system for the regulatory domain in which the non-AP STA is operating such as an AFC system with additional requirements specified by the regulatory domain.

A non-AP STA that is capable of operating as a STA 6G and has dot11ExtendedRegInfoSupport equal to true may transmit in a Non-AP STA Regulatory Connectivity element (see 9.4.2.311) in Probe Request frames and in (Re)Association Request frames to an HE AP that does not transmit a Country element. A non-AP STA that is capable of operating as a STA 6G and has dot11ExtendedRegInfoSupport equal to true shall transmit a Non-AP STA Regulatory Connectivity element (see 9.4.2.311) in (Re)Association Request frames to an AP that transmits a Country element.

The Maximum Transmit Power Category subfield in the Transmit Power Information field of the Transmit Power Envelope element is interpreted as shown in Table E-14 when operating in the 6 GHz band. This table describes the non-AP STAs for which a Transmit Power Envelope element with a given Maximum Transmit Power Category field value is applicable. Each regulatory domain might have additional regulations for each Maximum Transmit Power Category subfield value. Operation in such regulatory domains is subject to the additional regulations. Some values defined in Table E-14 might not be valid in all

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

regulatory domains. If a certain Maximum Transmit Power Category subfield encoding value is not valid in a regulatory domain, then the value is not used when operating in that regulatory domain.

Table E-14—Maximum Transmit Power Category subfield encoding

Value	Description
0	Default
1	Subordinate device A device that operates under the control of an indoor AP with additional requirements specified by the regulatory domain in which the AP is operating.
2–3	Reserved

An AP operating in the 6 GHz band shall send at least one Transmit Power Envelope element in Beacon and Probe Response frames as follows:

— Maximum Transmit Power Category subfield = Default; Maximum Transmit Power Interpretation subfield = Regulatory client EIRP PSD

When operating in the 6 GHz band in a regulatory domain in which a subordinate device (see Table E-14) is supported, an AP that is an indoor AP or indoor standard power AP per regulatory rules shall also send the following Transmit Power Envelope element in Beacon and Probe Response frames:

— Maximum Transmit Power Category subfield = Subordinate device; Maximum Transmit Power Interpretation subfield = Regulatory client EIRP PSD

An AP that transmits a Regulatory Information field indicating indoor standard power AP shall send at least one Transmit Power Envelope element in Beacon and Probe Response frames as follows:

— Maximum Transmit Power Category subfield = Default; Maximum Transmit Power Interpretation subfield = Additional regulatory client EIRP PSD

An *SP only client* is a non-AP STA that is capable of operating under the control of a standard power AP and is incapable of operating under the control of an indoor AP per regulatory rules. An *LPI only client* is a non-AP STA that is capable of operating under the control of an indoor AP and is incapable of operating under the control of a standard power AP per regulatory rules.

A regulatory client EIRP PSD value advertised by an AP that is a standard power AP shall be set to the highest value that meets the authorized client transmit power limits for the corresponding category obtained from the external system required by the regulatory rules, such as an AFC system, and any other client PSD regulatory rules for the corresponding 20 MHz channel.

A regulatory client EIRP PSD value advertised by an AP that is an indoor standard power AP shall be set o the higher of the following two values:

— The highest value that meets the authorized client transmit power limits for the corresponding category obtained from the external system required by the regulatory rules, such as an AFC system, and any other client PSD regulatory rules for the corresponding 20 MHz channel.

— The highest value that meets the LPI only client transmit power limits authorized by the regulatory rules for the corresponding category for the corresponding 20 MHz channel.

An additional regulatory client EIRP PSD value advertised by an AP that is an indoor standard power AP shall be set to the highest value that meets the authorized client transmit power limits for the corresponding

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

category obtained from the external system required by the regulatory rules, such as an AFC system, and any other client PSD regulatory rules for the corresponding 20 MHz channel.

If the regulatory client EIRP PSD values advertised by an AP that is a standard power AP or indoor standard power AP are insufficient to ensure that regulatory client limits on total EIRP are always met for all transmission bandwidths within the bandwidth of the AP's BSS, the AP shall also send a Transmit Power Envelope element in Beacon and Probe Response frames as follows:

— Maximum Transmit Power Category subfield = Default; Maximum Transmit Power Interpretation subfield = Regulatory client EIRP

NOTE 4—In the case of regulatory rules where the maximum transmit power for client devices is lower than the maximum transmit power for APs, the regulatory client maximum transmit power advertised by the AP for client devices might be lower than the regulatory client maximum transmit power the AP is authorized to use for its own transmissions.

If a non-AP STA receives a Transmit Power Envelope element with Maximum Transmit Power Category subfield that is not applicable to that non-AP STA, the non-AP STA may ignore that element.

NOTE 5—For example, if the non-AP STA is a subordinate device per regulatory rules and receives a Transmit Power Envelope element with Maximum Transmit Power Category subfield indicating a subordinate device, it may ignore any other received Transmit Power Envelope elements that indicate other values in the Maximum Transmit Power Category subfield.

NOTE 6—For example, if the non-AP STA is a device that, per regulatory rules, determines its regulatory client transmit power entirely using sources other than the AP (see 11.7.5), it can ignore all received Transmit Power Envelope elements with unit interpretation of Regulatory Client EIRP PSD or Regulatory Client EIRP from that AP.

An SP only client that is associated to an indoor standard power AP that receives, from the AP, one Transmit Power Envelope element with the Maximum Transmit Power Category subfield indicating Default and with the Maximum Transmit Power Interpretation subfield indicating Regulatory Client EIRP and another Transmit Power Envelope element with the Maximum Transmit Power Category subfield also indicating Default yet with the Maximum Transmit Power Interpretation subfield indicating Additional Regulatory Client EIRP shall comply with both elements.

An SP only client that is associated to an indoor standard power AP that receives, from the AP, one Transmit Power Envelope element with the Maximum Transmit Power Category subfield indicating Default and with the Maximum Transmit Power Interpretation subfield indicating Regulatory Client EIRP PSD and another Transmit Power Envelope element with the Maximum Transmit Power Category subfield also indicating Default yet with the Maximum Transmit Power Interpretation subfield indicating Additional Regulatory Client EIRP PSD shall comply with both elements.

NOTE 7—The Transmit Power Envelope element sent by an indoor standard power AP are insufficient for a client that is not an SP only client to determine its regulatory maximum power level; rather the client uses the regulatory maximum transmit power for the channel in the current regulatory domain known by the client from other sources following 11.7.5 and 11.7.6.

Annex G

(informative)

Frame exchange sequences

G.1 General

The allowable frame exchange sequences are defined using an extension of the EBNF format as defined in ISO/IEC 14977:1996 [B60]. The elements of this syntax that are used here are as follows:

- [a] = a is optional.
- {a} = a is repeated zero or more times.
- n{a} = a is repeated n or more times. For example, 3{a} requires 3 or more “a”. This notation is an extension to ISO/IEC 14977 and equivalent to n*a{a} as defined in that standard.
- a|b|c|... = selection between mutually exclusive alternatives, a, b, c ....
- ( ) = grouping, e.g., “a (b|c)” is equivalent to “a b | a c”.
- (* a *) = “a” is a comment. Comments are placed before the text they relate to.
- < > = order of frames not relevant. For example, <a b> is either “a b” or “b a”.
- A rule is terminated by a semicolon ‘;’
- The meaning of whitespace is changed from ISO/IEC 14977. The name of terminals do not contain whitespace, and the concatenate-symbol (comma in ISO/IEC 14977) is replaced by white space. Whitespace appearing between the names of terminals indicates concatenation. Otherwise, whitespace is not significant and is used to highlight the nesting of grouped terms.

Two types of terminals are defined:

- **Frames.** The name of a frame is shown in **bold** and identified by its type/subtype (e.g., **Beacon**, **Data**). Frames are shown with an initial capital letter.
- *Attributes.* The name of attributes are shown in *italic*. An attribute is introduced by the ‘+’ character. The attribute specifies a condition that applies to the frame (or alternatively, for the attributes that start +mu, the A-MPDU) that precedes it. Where there are multiple attributes applied, they are generally ordered in the same order of the fields in the frame to which they refer. The syntax a+(b|c) where b and c are attributes is equivalent to (a+b) | (a+c).

In this syntax the names of nonterminals are shown in a normal font, i.e., a sequence of words joined by hyphens (e.g., cf-frame-exchange-sequence).

The attributes are defined in Table G-1.

Table G-1—Attributes applicable to frame exchange sequence definition

Attribute	Description
a-mpdu	Frame is part of an A-MPDU aggregate. See NOTE 2.
a-mpdu-end	Frame is the last frame in an A-MPDU aggregate. See NOTE 2.
block-ack	QoS Data frame with Block Ack ack policy.
broadcast	Frame RA is the broadcast address.

Table G-1—Attributes applicable to frame exchange sequence definition *(continued)*

Attribute	Description
csi	An Action frame carrying channel state feedback (i.e., CSI, uncompressed beamforming, or compressed beamforming feedback matrices).
csi-request	A +HTC frame with the Feedback Request field equal to a value > 0.
delayed	BlockAck or BlockAckReq frame under a delayed policy.
DTIM	Beacon is a DTIM.
frag	Frame has its More Fragments subfield equal to 1.
group	Frame RA has Individual/Group bit equal to 1.
HTC	+HTC frame, i.e., a frame that contains the HT Control field, including the Control Wrapper frame. See NOTE 1.
I2R	ISTA to RSTA transmission
implicit-bar	QoS Data frame in an A-MPDU with Implicit BAR ack policy.
individual	Frame RA has Individual/Group bit equal to 0 or is sent to an AP or PCP.
last	Frame has its More Fragments subfield equal to 0.
action-no-ack	Management frame of subtype Action No Ack.
mfb	A +HTC frame with the MFB field is not equal to all 1s.
mrq	A +HTC frame with the MRQ subfield equal to 1.
mu-ppdu-end	This attribute delineates the end of a VHT MU PPDU. See NOTE 3 and NOTE 4.
mu-user-respond	The preceding frame or A-MPDU is part of a VHT MU PPDU and is addressed to a user from which an immediate response is expected. See NOTE 3 and NOTE 4.
mu-users-respond	The preceding frame or A-MPDU is part of an HE MU PPDU.
mu-user-not-respond	The preceding frame or A-MPDU is part of a VHT MU PPDU and is addressed to a user from which no immediate response is expected. See NOTE 3 and NOTE 4.
ndp-announce	A +HTC frame with the HT NDP Announcement subfield equal to 1.
no-ack	QoS Data frame with No Ack ack policy.
normal-ack	QoS Data frame with Normal Ack ack policy.
non-QAP	Frame is transmitted by a non-AP QoS STA.
non-stbc	PPDU TXVECTOR STBC parameter is equal to 0.
null	Data type Null Data subtype bit (Frame Control field B6) equal to 1.
pifs	Frame is transmitted following a PIFS.
QAP	Frame is transmitted by a QoS AP or a PCP.
QoS	Data type QoS subtype bit (Frame Control field B7) equal to 1.
R2I	RSTA to ISTA transmission
ranging-poll	Trigger frame of type Ranging Subtype Poll
ranging-secure-sound	Trigger frame of type Ranging Subtype Secure Sounding
ranging-sound	Trigger frame of type Ranging Subtype Sounding
RD	For a non-DMG STA, frame includes an HT Control field in which the RDG/More PPDU subfield is equal to 1. For a DMG STA, frame has RDG/More PPDU subfield in the QoS Control field equal to 1.
self	Frame RA = TA.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table G-1—Attributes applicable to frame exchange sequence definition *(continued)*

Attribute	Description
sounding	PPDU TXVECTOR SOUNDING parameter is present and equal to SOUNDING.
stbc	PPDU TXVECTOR STBC parameter is equal to a value >0.
to-ap	Frame is addressed to the AP.
trq	Frame is a +HTC frame with the TRQ field equal to 1.
non-S1GAP	Frame is transmitted by a non-AP S1G STA.
S1GAP	Frame is transmitted by an S1G AP.
CT	A frame that contains a control trailer.
TRN	A DMG PPDU that carries a TRN field.
ssw	TDD Beamforming frame with TDD Beamforming Frame Type subfield set to 0.
ssw-ack	TDD Beamforming frame with TDD Beamforming Frame Type subfield set to 2.
ssw-feedback	TDD Beamforming frame with TDD Beamforming Frame Type subfield set to 1.

NOTE 1—A Control frame that contains the HT Control field is always transmitted using the Control Wrapper frame.

NOTE 2—In the case of S-MPDU, a single MPDU is carried in an A-MPDU, but the attributes +*a-mpdu* and +*a-mpdu-end* are not used.

NOTE 3—+*mu-ppdu-end*, +*mu-user-respond* and +*mu-user-other* are used in productions that generate VHT MU PPDUs, according to the pattern: [“an A-MPDU (which might contain a S-MPDU) needing a response” +*mu-user-respond*] {“an A-MPDU (which might contain a S-MPDU) not needing a response” +*mu-user-not-respond*} +*mu-ppdu-end*. There is at least one of +*mu-user-respond* or +*mu-user-not-respond* in a VHT MU PPDU.

NOTE 4—In the sequence **A**+*mu-user-respond* **B**+*mu-user-not-respond* … +*mu-ppdu-end*, although the terms **A**, **B** … (which represent one or more frames) are listed sequentially in these productions, the per-user sequence of frames represented by **A**, **B**, ... are transmitted simultaneously per-user using a VHT MU PPDU.

G.2 Basic sequences

An allowable frame exchange sequence is defined by the rule frame-exchange-sequence. Except where modified by the *pifs* attribute, frames are separated by a SIFS or RIFS.

(* This rule defines all of the allowable frame exchange sequences *)
frame-exchange-sequence =

([**CTS**] (**Management** +*broadcast* | **Data** +*group*)) |
([**CTS** | **RTS CTS** | **PS-Poll**] {frag-frame **Ack**} last-frame **Ack**) |
(**PS-Poll Ack**) |
hcf-sequence |
mcf-sequence |
s1g-sequence |
dmg-sequence;

(* A frag-frame is a nonfinal part of an individually addressed MSDU or MMPDU *)
frag-frame = (**Data** | **Management**) +*individual* +*frag*;

(* This is the last (or only) part of a an individually addressed MSDU or MMPDU *)
last-frame = (**Data** | **Management**) +*individual* +*last*;

Annex H

(normative)

Usage of EtherType 89-0d

The MSDU with EtherType 89-0d is specified in Figure H-1.

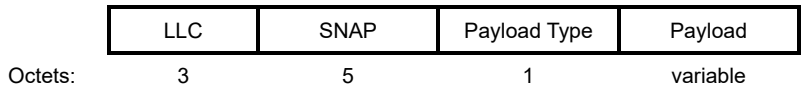

Figure H-1—MSDU with EtherType 89-0d frame

LLC is defined in ISO/IEC 8802-2:1998.

SNAP is defined in IEEE Std 802. The formatting of the SNAP header is according to IETF RFC 1042. The EtherType field is set to 89-0d.

The Payload Type field is set to one of the values in Table H-1.

Table H-1—Payload Type field values

Protocol name	Payload type	Subclause
Remote Request/Response	1	13.10.3
TDLS	2	11.20.2
FST	3	11.31.6
RLQP	4	11.22.3.4
Reserved	0, 5–255	

The Payload depends on the value inside the Payload Type field and is defined in the subclauses listed in Table H-1.

Annex I

(informative)

Examples of encoding a frame for OFDM PHYs, DMG PHYs, and EDMG PHYs

I.1 Example 1—BCC encoding

I.1.1 Introduction

The purpose of this annex is to show an example of encoding a frame for the OFDM PHY, as described in Clause 17. This example covers all of the encoding details defined by this standard.

The encoding illustration goes through the following stages:

a) Generating the short training sequence section of the preamble;
b) Generating the long preamble sequence section of the preamble;
c) Generating the SIGNAL field bits;
d) Coding and interleaving the SIGNAL field bits;
e) Mapping the SIGNAL field into frequency domain;
f) Pilot insertion;
g) Transforming into time domain;
h) Delineating the data octet stream into a bit stream;
i) Prepending the SERVICE field and adding the pad bits, thus forming the DATA;
j) Scrambling and zeroing the tail bits;
k) Encoding the DATA with a convolutional encoder and puncturing;
l) Mapping into complex 16-QAM symbols;
m) Pilot insertion;
n) Transforming from frequency to time and adding a circular prefix;
o) Concatenating the OFDM symbols into a single, time-domain signal.

In the description of time domain waveforms, a complex baseband signal at 20 Msample/s shall be used.

This example uses the 36 Mb/s data rate and a message of 100 octets. These parameters are chosen in order to illustrate as many nontrivial aspects of the processing as possible:

— Use of several bits per symbol (4 in this case);
— Puncturing of the convolutional code;
— Interleaving, which uses the LSB–MSB swapping stage;
— Scrambling of the pilot subcarriers.

In each Annex I table that has Binary value columns, the bit positions of the binary values are specified in the header of the table.

I.1.2 The message for the BCC example

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The message being encoded consists of the first 72 characters (shown in **bold** and including line breaks) of the well-known “Ode to Joy” by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power reunites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.
NOTE—The typo in "Fire-insired" is deliberate.

The message is converted to ASCII, using LF (0x0A) for line breaks; then it is prepended with an appropriate MAC header and an FCS is added. The resulting 100-octet PSDU is shown in Table I-1.

Table I-1—The message for the BCC example

The single period of the short training sequence is extended periodically for 161 samples (about 8 μs), and then multiplied by the window function:

$$W(k) = \begin{bmatrix} 0.5 & \text{k} = 0 \\ 1 & 1 \le k \le 159 \\ 0.5 & \text{k} = 160 \end{bmatrix}$$

The last sample serves as an overlap with the following OFDM symbol. The 161 samples vector is shown in Table I-4. The time-windowing feature illustrated here is not part of the normative specifications.

Table I-4—Time domain representation of the short sequence

The time domain representation is derived by performing IFFT on the contents of Table I-5, cyclically extending the result to get the cyclic prefix, and then multiplying with the window function given in I.1.3.1. The resulting 161 points vector is shown in Table I-6. The samples are appended to the short sequence section by overlapping and adding element 160 of Table I-4 to element 0 of Table I-6.

Table I-6—Time domain representation of the long sequence

I.1.4 Generation of the SIGNAL field

I.1.4.1 SIGNAL field bit assignment

The SIGNAL field bit assignment follows 17.3.4 and Figure 17-5. The transmitted bits are shown in Table I-7, where bit 0 is transmitted first.

Table I-7—Bit assignment for SIGNAL field

##	Bit	Meaning		##	Bit	Meaning
0	1	RATE: R1		12	0	—
1	0	RATE: R2		13	0	—
2	1	RATE: R3		14	0	—
3	1	RATE: R4		15	0	—
4	0	Reserved		16	0	LENGTH (MSB)
5	0	LENGTH (LSB)		17	0	Parity
6	0	—		18	0	SIGNAL TAIL
7	1	—		19	0	SIGNAL TAIL
8	0	—		20	0	SIGNAL TAIL
9	0	—		21	0	SIGNAL TAIL
10	1	—		22	0	SIGNAL TAIL
11	1	—		23	0	SIGNAL TAIL

I.1.4.2 Coding the SIGNAL field bits

7	1	15	1	23	0	31	0	39	0	47	0

I.1.4.3 Interleaving the SIGNAL field bits

The encoded bits are interleaved according to the interleaver of 17.3.5.7. A detailed breakdown of the interleaving operation is described in I.1.6.2. The interleaved SIGNAL field bits are shown in Table I-9.

Table I-9—SIGNAL field bits after interleaving

##	Bit	##	Bit	##	Bit	##	Bit	##	Bit	##	Bit
0	1	8	1	16	0	24	1	32	0	40	1

Four pilot subcarriers are added by taking the values {1.0,1.0,1.0,–1.0}, multiplying them by the first element of sequence $p_{0...126}$, given in Equation (17-22) (in 17.3.5.10), and inserting them into location {–21,–7,7,21}, respectively. The resulting frequency domain values are given in Table I-11.

Table I-11—Frequency domain representation of SIGNAL field with pilots inserted

I.1.4.5 SIGNAL field time domain

The time domain representation is derived by performing IFFT on the contents of Table I-11, extending cyclically, and multiplying by the window function

$$W(k) = \begin{bmatrix} 0.5 & \mathrm{k} = 0 \\ 1 & 1 \le k \le 79 \\ 0.5 & \mathrm{k} = 80 \end{bmatrix}.$$

The resulting 81 samples vector is shown in Table I-12. Note that the time-windowing feature illustrated here is not a part of the normative specifications.

Table I-12—Time domain representation of SIGNAL field

The SIGNAL field samples are appended with one sample overlap to the preamble, given in Table I-6.

I.1.5 Generating the DATA bits for the BCC example

I.1.5.1 Delineating, SERVICE field prepending, and zero padding

The transmitted message shown in Table I-1 contains 100 octets or, equivalently, 800 bits. The bits are prepended by the 16 SERVICE field bits and are appended by 6 tail bits. The resulting 822 bits are appended by some number of bits with value 0 to yield an integer number of OFDM symbols. For the 36 Mb/s mode, there are 144 data bits per OFDM symbol; the overall number of bits is $\lceil 822/144 \rceil \times 144 = 864$. Hence, 864 – 822 = 42 zero bits are appended.

The DATA bits are shown in Table I-13.

Table I-13—The DATA bits before scrambling

I.1.6.2 Interleaving the DATA bits

The interleaver is defined as a two-permutation process. The index of the coded bit before the first permutation shall be denoted by *k*; *i* shall be the index after the first and before the second permutation; and *j* shall be the index after the second permutation, just prior to modulation mapping. The mapping from *k* to *i* is shown in Table I-17, and the mapping from *i* to *j* is shown in Table I-18.

As a specific example, consider the case of $k = 17$ (the 18^{th} bit after encoding and puncturing). It is mapped by the first permutation to $i = 13$ and by the second permutation to $j = 12$ (the 13^{th} bit before mapping).

I.1.6.3 Mapping into symbols

The frequency domain symbols are generated by grouping 4 coded bits and mapping into complex 16-QAM symbols according to Table 17-17 (in 17.3.5.8). For instance, the first 4 bits (0 1 1 1) are mapped to the complex value, –0.316 + 0.316j, inserted at subcarrier #26.

Four pilot subcarriers are added by taking the values {1.0,1.0,1.0,–1.0}, multiplying them by the second element of sequence p, given in Equation (17-22) (in 17.3.5.10), and inserting them into location {–21,–7,7,21}, respectively.

The frequency domain is shown in Table I-20.

Table I-20—Frequency domain of first DATA symbol

–17	–0.316	0.316		–1	–0.949	0.949		15	0.949	–0.949		31	0.000	0.000

The time domain samples are produced by performing IFFT, cyclically extending, and multiplying with the window function in the same manner as described in I.1.4.5. The time domain samples are appended with one sample overlap to the SIGNAL field symbol.

I.1.7 Generating the additional DATA symbols

The generation of the additional five data symbols follows the same procedure as described in Clause 4. Special attention should be paid to the scrambling of the pilot subcarriers. Table I-21 lists the polarity of the pilot subcarriers and the elements of the sequence $p_{0...126}$ for the DATA symbols. For completeness, the pilots in the SIGNAL are included as well. The symbols are appended one after the other with a one-sample overlap.

Table I-21—Polarity of the pilot subcarriers

i	OFDM symbol	Element of p_i	Pilot at #–21	Pilot at #–7	Pilot at #7	Pilot at #21
0	SIGNAL	1	1.0 +0 j	1.0 +0 j	1.0 +0 j	–1.0 +0 j
1	DATA 1	1	1.0 +0 j	1.0 +0 j	1.0 +0 j	–1.0 +0 j
2	DATA 2	1	1.0 +0 j	1.0 +0 j	1.0 +0 j	–1.0 +0 j

Table I-21—Polarity of the pilot subcarriers

3	DATA 3	1	1.0 +0 j	1.0 +0 j	1.0 +0 j	–1.0 +0 j
4	DATA 4	–1	–1.0 +0 j	–1.0 +0 j	–1.0 +0 j	1.0 +0 j
5	DATA 5	–1	–1.0 +0 j	–1.0 +0 j	–1.0 +0 j	1.0 +0 j
6	DATA 6	–1	–1.0 +0 j	–1.0 +0 j	–1.0 +0 j	1.0 +0 j

I.1.8 The entire PPDU for the BCC example

The PPDU in its entirety is shown in the tables in this subclause. These tables illustrate the short training sequence section (Table I-22), the long training sequence section (Table I-23), the SIGNAL field (Table I-24), and the six DATA symbols (Table I-25 to Table I-30).

I.2 Generating encoded DATA bits—LDPC example 1

I.2.1 General

LDPC example 1 is similar to the BCC example. This example illustrates LDPC shortening, encoding, and puncturing of a single codeword.

Input TXVECTOR parameters for LDPC example 1:

— FEC_CODING = LDPC_CODING = 1 (LDPC encoder; not BCC)
— CH_BANDWIDTH = HT_CBW20 = 0 (CH_BANDWIDTH = 0 => 20 MHz)
— MCS = 4 (MCS = 4; 16-QAM; Coding rate = 3/4)
— Coding rate R = 3/4
— LENGTH = 100 octets (with 16-bit SERVICE field becomes 102 Octets = 816 bits to scramble and encode)
— STBC = 0 (STBC = 0 => OFF; m_STBC=1)

I.2.2 The message for LDPC example 1

The message being encoded consists of the first 72 characters (shown in **bold** and including line breaks) of the well-known “Ode to Joy” by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread
Thy sanctuary.
Thy magic power reunites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.

NOTE 1—The typo in "Fire-insired" is deliberate.

The message is converted to ASCII, using LF (0x0A) for line breaks; then it is prepended with an appropriate MAC header, and an FCS is added. The resulting 100-octet PSDU is shown in Table I-31.

NOTE 2—The message for LDPC example 1 is identical to the message for the BCC example; in other words, the FCS field (octets 97–100) has the same value.

NOTE 3—The DurationID field (i.e., octets 3 and 4) remains 0x02E = 46 μs.

96...100	0x61	0x67	0x33	0x21	0xB6

I.2.3 Prepending the SERVICE field for LDPC example 1

The transmitted message shown in Table I-31 contains 100 octets, or equivalently, 800 bits. The bits are prepended by the 16 SERVICE field bits (bits 0–15 in Table I-32), as defined in 19.3.11.2, but tail bits and padding bits are not appended as in the BCC example. The resulting 816 bits are shown in Table I-32.

Table I-32—DATA bits for LDPC example 1 before scrambling

I.2.4 Scrambling LDPC example 1

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The 816 bits are scrambled by the scrambler defined in 17.3.5.5. The initial state of the scrambler is the state 1011101 binary (0x5D). The scrambled sequence is given in Table I-33.

NOTE—The scrambled entries for the correct FCS field value are given in bits 784–815.

Table I-33—DATA bits for LDPC example 1 after scrambling

Bit ##	Binary value B0 B7	Binary value B8 B15	Binary value B16 B23	Hexadecimal value	Hexadecimal value	Hexadecimal value

I.2.5 Inserting shortening bits for LDPC example 1

The equations of 19.3.11.7.5 are solved to calculate the following derived parameters for LDPC example 1 from the input TXVECTOR parameters:

— $N_{CW} = 1$ (number of codewords)
— $L_{LDPC} = 1944$ (size of codeword)
— $N_{CBPS} = 208$ (number of coded bits per symbol)
— $N_{avbits} = 1248$ (number of available bits)
— $N_{shrt} = 642$ (number of bits to be shortened)
— $N_{punc} = 54$ (number of bits to be punctured)
— $N_{SYM} = 6$ (number of OFDM symbols)
— $N_{rep} = 0$ (number of bits to be repeated)

The results of applying shortening bits, as prescribed in paragraph (c) of 19.3.11.7.5, is given in Table I-34.

NOTE—$N_{shrt} = 642$ shortening bits have been inserted as 0s in bits 816–1457.

I.2.6 Encoding data for LDPC example 1

The DATA with shortening bits are LDPC encoded as a single (N_{CW}=1) codeword (L_{LDPC}=1944; R=3/4) as prescribed by paragraph (c) of 19.3.11.7.5. The results are given in Table I-35.
NOTE—The LDPC encoder appends 486 bits (i.e., bits 1458–1943) after the shortening bits.

Table I-35—DATA bits for LDPC example 1 after LDPC encoding

I.2.7 Removing shortening bits and puncturing for LDPC example 1

The shortening bits, applied before LDPC encoding, are now removed as prescribed in paragraph (c) of 19.3.11.7.5. Finally, either puncturing is applied as described in paragraph (d) of the same subclause, or the copying of repeated bits is applied as described in paragraph (e) of the same subclause. In LDPC example 1, because N_{punc} = 54 is nonzero and N_{rep} = 0, puncturing is prescribed and completes the LDPC encoding process.

The results are given in Table I-36.

NOTE—The N_{shrt} = 642 shortening bits have been removed, and the N_{punc} = 54 bits have been punctured from Table I-35 to produce bits 816–1247 of Table I-36.

I.3 Generating encoded DATA bits—LDPC example 2

I.3.1 General

LDPC example 2 exercises the alternative branches of the LDPC encoding procedure not exercised in LDPC example 1. Example 2 also exhibits LDPC shortening, encoding, and padding by repetition and employs multiple codewords and diversifies the TXVECTOR parameters—all without making the length of this example cumbersome.

The length of the text of the message is increased by 40 octets, from 72 characters to 112 characters, in order to illustrate padding (rather than puncturing) and encoding of multiple codewords.

Input TXVECTOR parameters for LDPC example 2:

- FEC_CODING = LDPC_CODING = 1 (LDPC encoder; not BCC)
- CH_BANDWIDTH = HT_CBW40 = 1 (CH_BANDWIDTH = 1 => 40 MHz)
- MCS = 1 (MCS = 1; QPSK; coding rate = 1/2)
- Coding rate R = 1/2
- LENGTH = 140 octets (with 16-bit SERVICE field becomes 142 octets = 1136 bits to scramble and encode)
- STBC = 1 (STBC = 1 => ON; m_STBC = 2)

I.3.2 The message for LDPC example 2

The message being encoded consists of the first 112 characters (shown in **bold** and including line breaks) of the well-known “Ode to Joy” by F. Schiller:

Joy, bright spark of divinity,
Daughter of Elysium,
Fire-insired we tread

Thy sanctuary.
Thy magic power reunites
All that custom has divided,
All men become brothers
Under the sway of thy gentle wings.
NOTE—The typo in "Fire-insired" is deliberate.

The message is converted to ASCII, using LF (0x0A) for line breaks; then it is prepended with an appropriate MAC header and an FCS is added. The resulting 140-octet PSDU is shown in Table I-37.

Because of the additional 40 characters, note that the message for LDPC example 2 has a different FCS field (octets 137–140) than the previous examples and that the DurationID field (i.e., octets 3 and 4) changes to 0x036 = 54 μs.

Table I-37—Message for LDPC example 2

I.3.3 Prepending the SERVICE field for LDPC example 2

The transmitted message shown in Table I-37 contains 140 octets, or equivalently, 1120 bits. The bits are prepended by the 16 SERVICE field bits (bits 0–15 in Table I-38), as defined by 19.3.11.2, but tail bits and padding bits are not appended as in the BCC example. The resulting 1136 bits are shown in Table I-38.

I.3.4 Scrambling LDPC example 2

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The 1136 bits are scrambled by the scrambler defined in 17.3.5.5. The initial state of the scrambler is the state 1011101 binary (0x5D). The scrambled sequence is given in Table I-39.

Table I-39—DATA bits for LDPC example 2 after scrambling

I.3.5 Inserting the shortening bits for LDPC example 2

The equations of 19.3.11.7.5 are solved to calculate the following derived parameters for LDPC example 2 from the input TXVECTOR parameters:

- $N_{CW} = 2$ (number of codewords)
- $L_{LDPC} = 1296$ (size of codeword)
- $N_{CBPS} = 216$ (number of coded bits per symbol)
- $N_{avbits} = 2592$ (number of available bits)
- $N_{shrt} = 160$ (number of bits to be shortened)
- $N_{punc} = 0$ (number of bits to be punctured)
- $N_{SYM} = 12$ (number of OFDM symbols)
- $N_{rep} = 160$ (number of bits to be repeated)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The results of applying shortening bits, as prescribed in paragraph (c) of 19.3.11.7.5, is given in Table I-40.
NOTE—N_{shrt} = 160 shortening bits have been inserted as 0s: 80 0s at bits 568–647 and 80 0s at bits 1216–1295; this order equally distributes the shortening bits across the N_{CW} = 2 codewords.

Table I-40—DATA bits for LDPC example 2 after insertion of shortening bits

I.3.6 Encoding the data for LDPC example 2

The DATA with shortening bits are LDPC encoded as two (N_{CW} = 2) codewords (L_{LDPC} = 1296; R = 1/2) as prescribed by paragraph (c) of 19.3.11.7.5. The results are given in Table I-41.

NOTE—The LDPC encoder appends 648 bits as follows: bits 648–1295 after the first shortened codeword and another 648 bits (bits 1944–2591) after the second shortened codeword.

I.3.7 Removing shortening bits and repetition for LDPC example 2

2448–2471	00000101	00011000	00101000	0x05	0x18	0x28
2472–2495	11110011	00111001	11011000	0xF3	0x39	0xD8
2496–2519	00010001	01110101	00010111	0x11	0x75	0x17
2520–2543	11011101	11111011	11010010	0xDD	0xFB	0xD2
2544–2567	10101010	11101011	10100110	0xAA	0xEB	0xA6
2568–2591	10000101	10110011	01011000	0x85	0xB3	0x58

The shortening bits, applied before LDPC encoding, are now removed as prescribed in paragraph (c) of 19.3.11.7.5. Finally, either puncturing is applied as described in paragraph (d) of the same subclause, or the copying of repeated bits is applied as described in paragraph (e) of the same subclause. In LDPC example 2, because $N_{punc} = 0$ and $N_{rep} = 160$ are nonzero, repetition is prescribed and completes the LDPC encoding process.

The results are given in Table I-42.

NOTE—The first 80 shortening bits (bits 568–647 from Table I-41) have been removed from the first codeword between bits 567 and 568 of Table I-42, and the second 80 shortening bits (bits 1864–1943 of Table I-41) have been removed between bits 1215 and 1216 of Table I-42. Also, 80 bits have been repeated from the beginning of the first codeword (bits 0–79) to the end of the first codeword (bits 1216–1295), and 80 bits have been repeated from the beginning of the second codeword (bits 1296–1375) to end of the second codeword (bits 2512–2591) in Table I-42.

I.4 DMG example data vectors

I.5, I.6, and I.7 contain example data vectors for the DMG PHY (see Clause 20).

For each described node, there is a cross-reference in this annex that is of the form

Reference: <**filename.txt**>

where the named file is one of the text files contained in the DMGEncodingExamples.zip file embedded in the IEEE 802.11 Working Group document 11-12/0751r1, located at https://mentor.ieee.org/802.11/dcn/12/11-12-0751-01-00ad-dmg-encoding-examples.docx).

Depending on the node being illustrated, the text file might represent bit data, symbol data, or sample data:

- For bit data, the text file contains a time ordered sequence of 1 and 0 characters, separated by spaces and without any carriage control characters.
- For symbol data, the text file contains a time ordered sequence of signed integers, separated by spaces and without any carriage control characters.
- For sample data, the text file contains a time ordered sequence of complex values, formatted as ±<re>±<im>j, separated by spaces and without any carriage control characters.

When referencing specific bits, symbols, or samples in the files, they are considered to be numbered starting from 1.

This formatting of the text files has been chosen to facilitate import into other tools. For example, the files can be read using the MATLAB `dlmread('filename')` command.

For DMG control mode, SC mode and low-power (LP) SC mode modulation samples, no spectrum shaping has been applied to the data because the implementation of spectrum shaping is not defined in this standard.

I.5 DMG Example 1—DMG control mode encoding

I.5.1 DMG control mode preamble

The DMG control mode preamble Short Training field (STF) and Channel Estimation field (CEF) are each constructed from a concatenation of real valued bipolar Golay sequences that is π/2-BPSK modulated, as shown in Figure I-1.

The DMG control mode preamble is 7552 samples long.

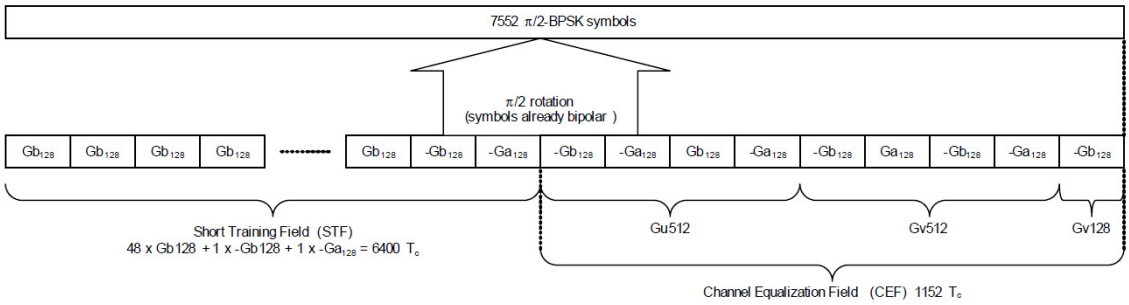

Figure I-1—DMG control mode preamble expressed in Ga_{128} and Gb_{128} sequences

I.5.2 Control mode header

I.5.2.1 General

The DMG control mode header coding and modulation are shown in Figure I-2.

I.5.2.2 DMG control mode header and payload bits

Figure I-2 node ①. The 5 octets of header data followed by the payload data. The first 6 octets of the data payload are used to complete the construction of the single LDPC codeword of the DMG control mode header. For this example, the DMG control mode header fields are set as listed in Table I-43.

The data payload octets are provided by a count, modulo 256, starting at 0. The resulting header and payload sequence is 1000 bits long, of which the first 88 bits are encoded in the header modulation block. For this example, with a payload of 120 octets, $L_{DPFCW} = 88$, $L_{DPCW} = 152$ and $L_{DPLCW} = 152$.

These numbers illustrate that the payload is not simply packed 168 bits at a time into the LDPC encoding, with the last few bits (modulo 168) in the last PPDU getting disproportionate coding gain. The specified calculation spreads the excess coding gain evenly across all of the packets, so the number of payload bits in each packet varies between approximately 120 and the maximum 168.

Reference: Bits 1 to 88 of the file **CPHY_Header and Payload bits.txt**

Table I-43—DMG control mode header settings

Field	Value
Scrambler Initialization	2
Length	120

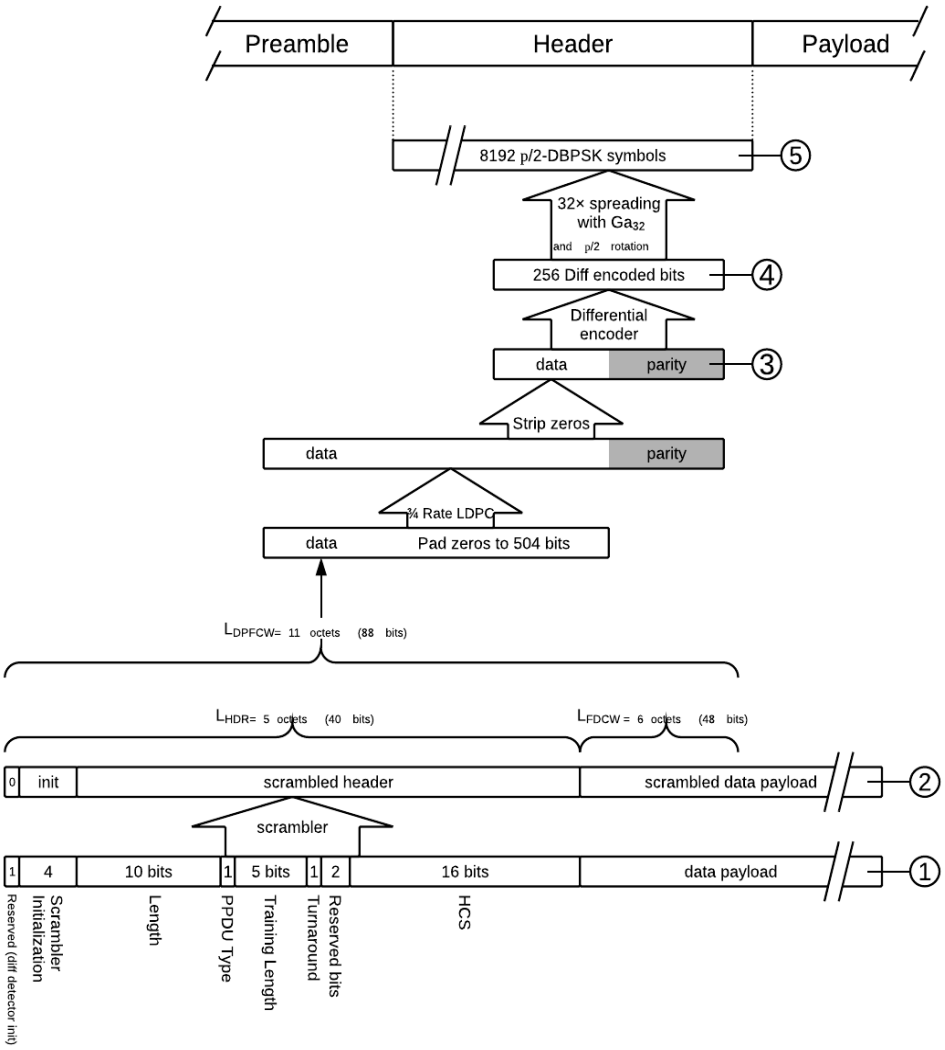

Figure I-2—DMG control mode header coding and modulation

I.5.2.3 DMG control mode scrambled header and payload bits

Figure I-2 node ②. The 5 header plus 6 data = 11 octets after scrambling.

Reference: Bits 1 to 88 of the file **CPHY_Scrambled Header and Payload bits.txt**

I.5.2.4 DMG control mode LDPC encoded header bits

Figure I-2 node ③. In this example there are 7 LDPC codewords. The number of bits produced by the first codeword after zero stripping is 88 + 168 = 256, and the number of bits produced by each of the remaining 6 codewords is 152 + 168 = 320. The total number of bits after LDPC encoding is 256 + 6 x 320 = 2176, of which the first 256 bits correspond to the LDPC encoded header.

Reference: Bits 1 to 256 of the file **CPHY_LDPC Encoded Header and Payload bits.txt**

I.5.2.5 DMG control mode differentially encoded header symbols

Figure I-5 node ⑤. The 448 bit concatenated CS1/CS2 sequence including the PN scrambling of CS2.

Reference: **SCPHY_MCS2_Final CS1 CS2 Sequence bits.txt**

I.6.2.7 DMG SC mode header samples

Figure I-5 node ⑥. The fully modulated signal after BPSK mapping, duplication (with negation), guard interval addition and π/2 rotation are applied.

The 448 header bits are BPSK mapped to 448 modulation symbols and increased to 512 symbols by the addition of a 64 symbol guard interval. A second, negated, copy of the 448 modulation symbols is also increased to 512 symbols by the addition of a 64 symbol guard interval. The two 512 symbol blocks are concatenated and π/2 rotated to create 1024 samples.

Reference: **SCPHY_MCS2_Header Samples.txt**

I.6.3 DMG SC mode payload

I.6.3.1 General

The DMG SC mode payload coding and modulation are shown in Figure I-6 (for MCS1) and Figure I-7 (for MCS2–MCS12).

I.6.3.2 DMG SC mode MCS 1 payload

I.6.3.2.1 Payload bits

Figure I-6 node ①. The payload at node ① is a count, modulo 256, starting at 0.

For MCS 1 each rate 1/2 LDPC codeword encodes 168 bits (with $\rho = 2$ repetition) so the payload padding calculation gives $N_{CW} = 48$ and $N_{DATA\_PAD} = 64$.

There are 1000 × 8 = 8000 payload bits plus 64 padding bits giving a total of 8 064 bits.

Reference: **SCPHY_MCS1_Payload bits.txt**

I.6.3.2.2 Scrambled payload bits

Figure I-6 node ②. All 8 064 bits are scrambled according to a scrambler initialization value of 66.

Reference: **SCPHY_MCS1_Scrambled Payload bits.txt**

I.6.3.2.3 Rate 1/2 LDPC encoded bits before scrambled duplication

Figure I-6 node ③. The rate 1/2 LDPC encoding of each block of $L_z = 168$ scrambled payload bits plus $L_z = 168$ padding zero bits. In this example, the 8064 actual payload bits are doubled, by repetition, to an effective payload of 16 128 bits, then doubled again to 32 256 bits by LDPC encoding.

This node, unique to MCS 1, is the raw LDPC encoded payload bits before scrambled duplication.

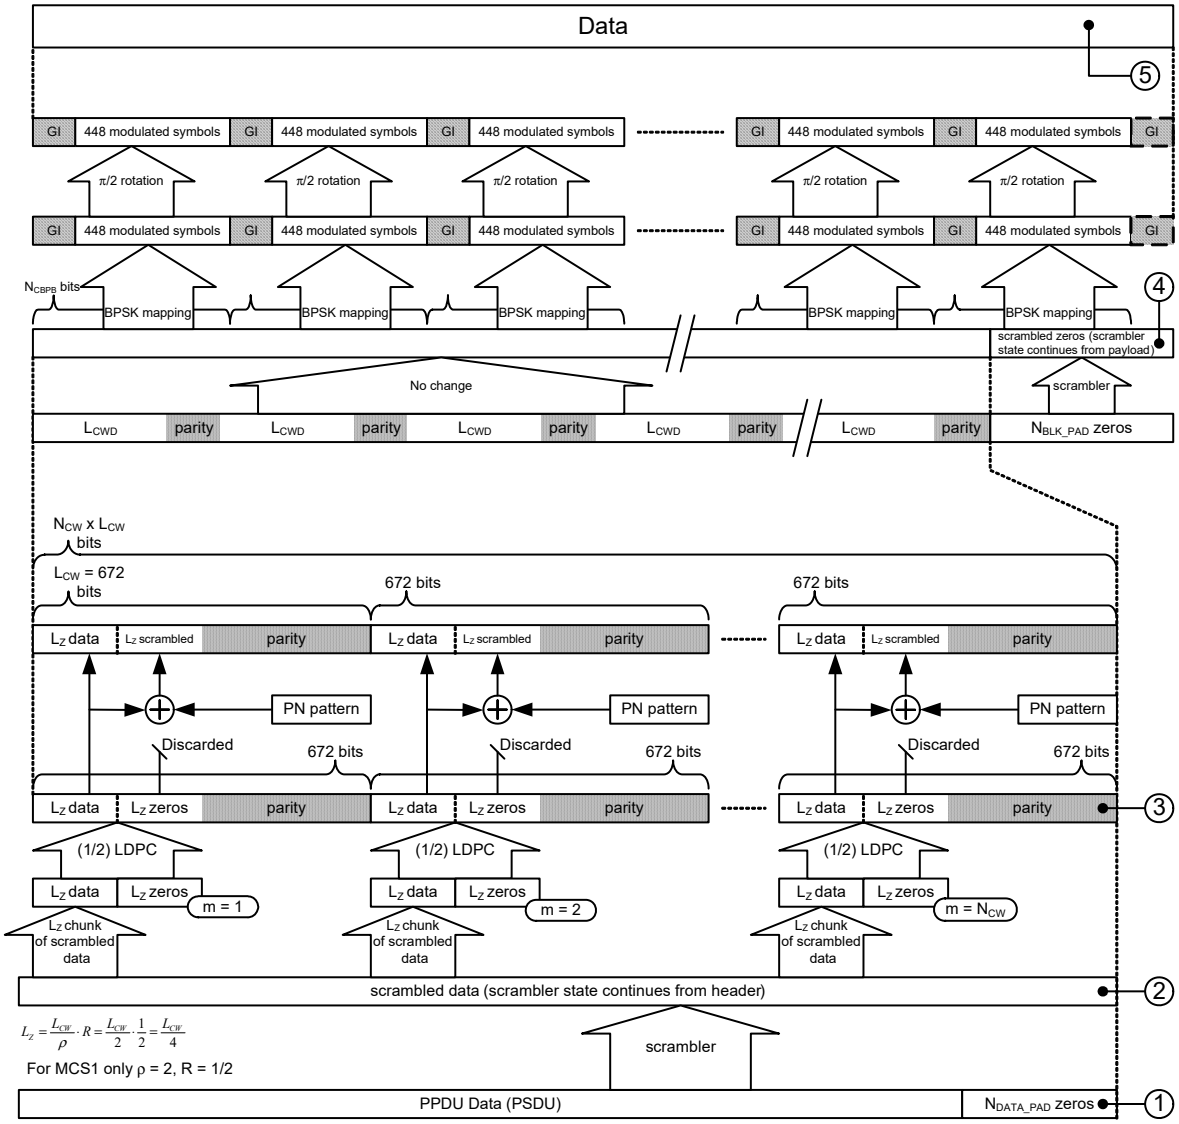

Figure I-6—DMG SC mode MCS 1 payload coding and modulation

I.6.3.2.4 Rate 1/2 LDPC encoded bits after scrambled duplication

Figure I-6 node ④. The LDPC codewords after the $L_z = 168$ 0s have been replaced by the $L_z = 168$ rescrambled data octets. The data at this node also includes the appended N_{BLK_PAD} scrambled 0s; however, in this example, $N_{BLK\_PAD} = 0$, so there are still 32 256 bits.

Each 448 bits in the reference file is the $N_{CBPB} = 448$ bits required to build a modulation block of the MCS 1 payload.

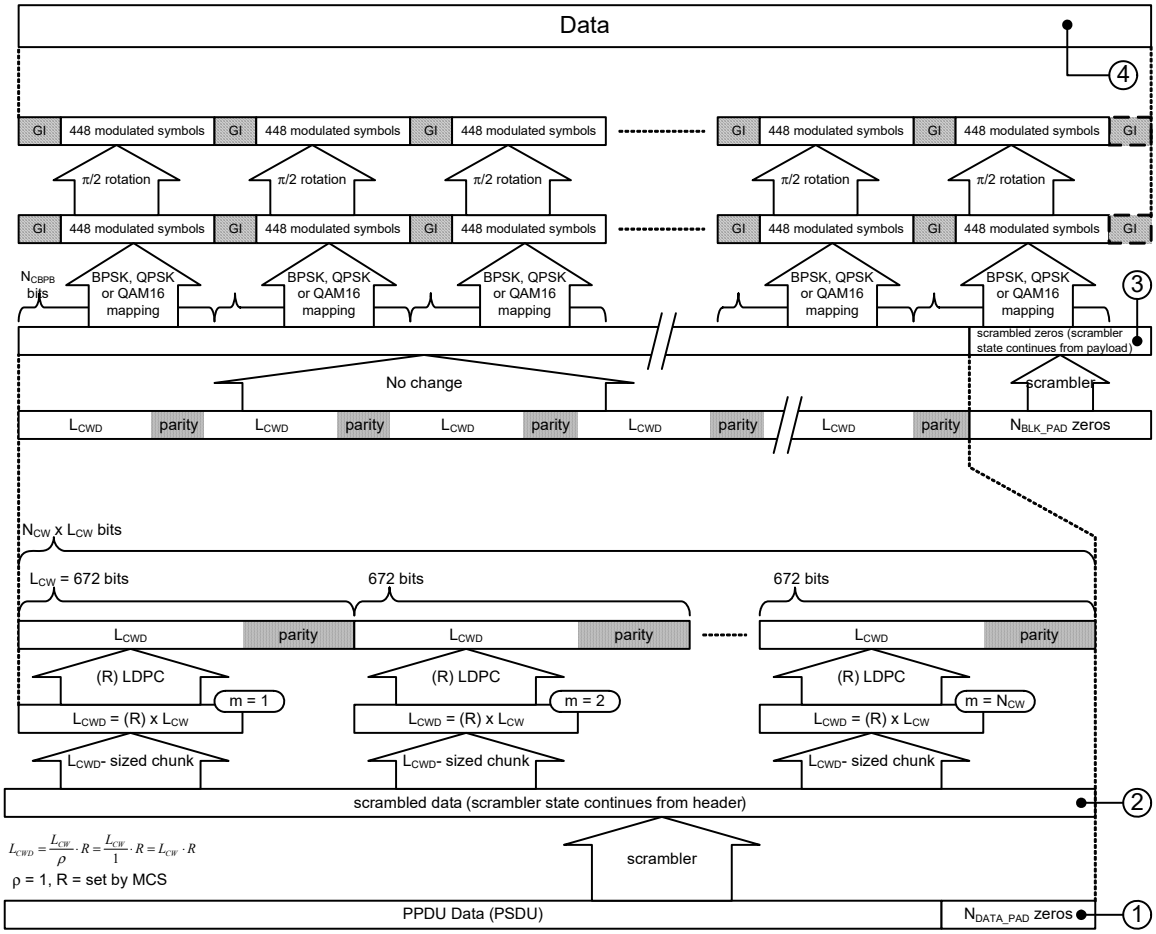

Figure I-7—DMG SC mode MCS 2—MCS 12 payload coding and modulation

I.6.3.2.5 Payload samples

Figure I-6 node ⑤. The modulated signal after BPSK mapping, guard interval addition and π/2 rotation has been applied.

In this example, the 32 256 encoded bits are divided into 72 × 448 bit blocks. BPSK mapping converts this to 72 × 448 modulation symbols which the guard interval increases to 72 × 512 modulation symbols. When the closing 64-symbol guard interval is added, it results in a total of 72 × 512 + 64 = 36 928 payload samples.

Reference: **SCPHY_MCS1_Payload Samples.txt**

I.6.3.3 DMG SC mode MCS 5 payload

I.6.3.3.1 Payload bits

Figure I-7 node ①. The payload at node ① is a count, modulo 256, starting at 0.

For MCS 5 each rate 13/16 LDPC codeword encodes 546 bits so the payload padding calculation gives N_{CW} = 15 and N_{DATA_PAD} = 190.

There are 1000 × 8 = 8000 payload bits plus 190 padding bits giving a total of 8 190 bits.

Reference: **SCPHY_MCS5_Payload bits.txt**

I.6.3.3.2 Scrambled payload bits

Figure I-7 node ②. All 8 190 bits are scrambled according to a scrambler initialization value of 66.

Reference: **SCPHY_MCS5_Scrambled Payload bits.txt**

I.6.3.3.3 Rate 13/16 LDPC encoded payload bits

Figure I-6 node ③. The rate 13/16 LDPC encoding of each block of L_{CWD} = 546 scrambled payload bits. In this example, the 8 190 payload bits are increased to 10 080 bits by the LDPC encoding.

The data at this node also includes the appended N_{BLK_PAD} scrambled 0s. In this example, N_{BLK_PAD} = 224, so the total number of bits is 10 080 + 224 = 10 304.

Reference: **SCPHY_MCS5_LDPC Encoded Payload Bits.txt**

I.6.3.3.4 Payload samples

Figure I-7 node ④. The modulated signal after BPSK mapping, guard interval addition and π/2 rotation has been applied.

In this example, the 10 304 encoded bits are divided into 23 × 448 bit blocks. BPSK mapping converts this to 23 × 448 modulation symbols which the guard interval increases to 23 × 512 modulation symbols. When the closing 64-symbol guard interval is added, it results in a total of 23 × 512 + 64 = 11 840 payload samples.

Reference: **SCPHY_MCS5_Payload Samples.txt**

I.6.3.4 DMG SC mode MCS 7 payload

I.6.3.4.1 Payload bits

Figure I-7 node ①. The payload at node ① is a count, modulo 256, starting at 0.

For MCS 7 each rate 5/8 LDPC codeword encodes 420 bits so the payload padding calculation gives N_{CW} = 20 and N_{DATA_PAD} = 400.

There are 1000 × 8 = 8000 payload bits plus 400 padding bits giving a total of 8 400 bits.

Reference: **SCPHY_MCS7_Payload bits.txt**

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

I.6.3.4.2 Scrambled payload bits

Figure I-6 node ②. All 8 400 bits are scrambled according to a scrambler initialization value of 66.

Reference: **SCPHY_MCS7_Scrambled Payload bits.txt**

I.6.3.4.3 Rate 5/8 LDPC encoded payload bits

Figure I-7 node ③. The rate 5/8 LDPC encoding of each block of L_{CWD} = 420 scrambled payload bits. In this example, the 8 400 payload bits are increased to 13 440 bits by the LDPC encoding.

The data at this node also includes the appended N_{BLK_PAD} scrambled 0s. In this example, N_{BLK_PAD} = 0, so there are still a total of 13 440 bits.

Reference: **SCPHY_MCS7_LDPC Encoded Payload Bits.txt**

I.6.3.4.4 Payload samples

Figure I-7 node ④. The modulated signal after QPSK mapping, guard interval addition and π/2 rotation has been applied.

In this example, the 13 440 encoded bits are divided into 15 × 896 bit blocks. QPSK mapping converts this to 15 × 448 modulation symbols which the guard interval increases to 15 × 512 modulation symbols. When the closing 64-symbol guard interval is added, it results in a total of 15 × 512 + 64 = 7 744 payload samples.

Reference: **SCPHY_MCS7_Payload Samples.txt**

I.6.3.5 DMG SC mode MCS 12 payload

I.6.3.5.1 Payload bits

Figure I-7 node ①. The payload at node ① is a count, modulo 256, starting at 0.

For MCS 12 each rate 3/4 LDPC codeword encodes 504 bits so the payload padding calculation gives N_{CW} = 16 and N_{DATA_PAD} = 64.

There are 1000 × 8 = 8000 payload bits plus 64 padding bits giving a total of 8 064 bits.

Reference: **SCPHY_MCS12_Payload bits.txt**

I.6.3.5.2 Scrambled payload bits

Figure I-7 node ②. All 8 064 bits are scrambled according to a scrambler initialization value of 66.

Reference: **SCPHY_MCS12_Scrambled Payload bits.txt**

I.6.3.5.3 Rate 3/4 LDPC encoded payload bits

Figure I-7 node ③. The rate 3/4 LDPC encoding of each block of L_{CWD} = 504 scrambled payload bits. In this example, the 8 064 payload bits are increased to 10 752 bits by the LDPC encoding.

The data at this node also includes the appended N_{BLK_PAD} scrambled 0s. In this example, N_{BLK_PAD} = 0, so there are still a total of 10 752 bits.

Reference: **SCPHY_MCS12_LDPC Encoded Payload Bits.txt**

I.6.3.5.4 Payload samples

Figure I-7 node ④. The modulated signal after 16-QAM mapping, guard interval addition and π/2 rotation has been applied.

In this example, the 10 752 encoded bits are divided into 6 × 1 792 bit blocks. 16-QAM mapping converts this to 6 × 448 modulation symbols which the guard interval increases to 6 × 512 modulation symbols. When the closing 64-symbol guard interval is added, it results in a total of 6 × 512 + 64 = 3 136 payload samples.

Reference: **SCPHY_MCS12_Payload Samples.txt**

I.7 DMG Example 3—DMG low-power SC mode encoding

I.7.1 Introduction

The DMG low-power SC mode is obsolete.

I.7.2 DMG low-power SC mode preamble

The DMG low-power SC mode preamble is identical to the DMG SC mode preamble.

I.7.3 DMG low-power SC mode header

The DMG low-power SC mode header fields are the same as the DMG SC mode header fields. The DMG low-power SC mode header is encoded and modulated in the same way as the DMG SC mode header.

I.7.4 DMG low-power SC mode MCS 26 payload

I.7.4.1 General

The DMG low-power SC mode payload coding and modulation are shown in Figure I-8.

I.7.4.2 Payload bits

Figure I-8 node ①. The payload at node is a count, modulo 256, starting at 0.

For MCS 26, the DMG low-power SC mode payload padding calculation gives $N_{DATA\_PAD} = 368$; however, unlike the other modes, this padding data is not appended before FEC computation.

So there are just 1000 × 8 = 8000 payload bits.

Reference: **LPSCPHY_MCS26_Payload bits.txt**

I.7.4.3 Scrambled payload bits

Figure I-8 node ②. All 8000 bits are scrambled according to a scrambler initialization value of 66.

Reference: **LPSCPHY_MCS26_Scrambled Payload bits.txt**

Copyright © 2025 IEEE. All rights reserved.

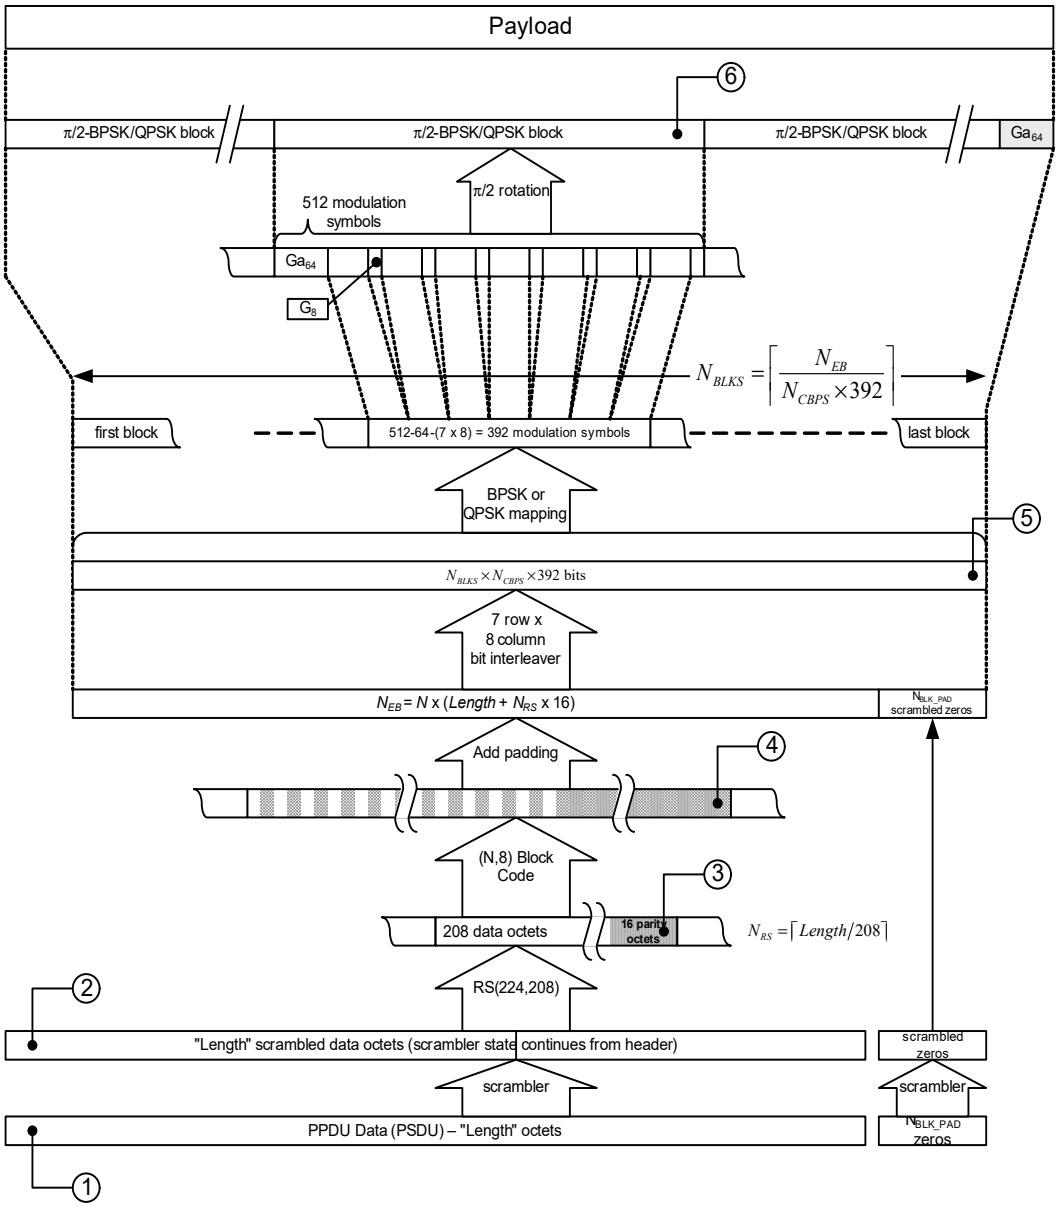

Figure I-8—DMG low-power SC mode payload coding and modulation

I.7.4.4 RS(224,208) encoded payload bits

Figure I-8 node ③. In this example, there are 4 RS(224,208) codewords and one shortened RS(184,168) codeword, giving a total of (4 × 224 + 1 × 184) × 8 = 8 640 bits at this node.

Reference: **LPSCPHY_MCS26_RS(224,208) Output bits.txt**

I.7.4.5 (12,8) block coded payload bits

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Figure I-8 node ④. The (12,8) block coder increases the effective bits from 8 640 to 12 960.

Reference: **LPSCPHY_MCS26_Block Coded Payload bits.txt**

I.7.4.6 Interleaved payload bits

Figure I-8 node ⑤. Before interleaving the block coder output is padded with $N_{DATA\_PAD} = 368$ scrambled 0s to give 13 328 bits (34 x 392). The interleaver then redistributes these bits in time, as specified.

Reference: **LPSCPHY_MCS26_RS Encoded and Interleaved Payload bits.txt**

I.7.4.7 Payload samples

Figure I-8 node ⑥. Each block of 392 bits from the interleaver output is BPSK mapped to 392 modulation symbols, prepended with a Ga_{64} sequence as a guard interval and punctuated by G_8 (last 8 samples of Ga_{64}) guard intervals, then π/2 rotated, thus resulting in a 512 symbol π/2-BPSK modulation block.

In this example, there are 34 modulation blocks and, as specified, the last one is followed by a terminating Ga_{64} guard interval sequence, so there are 34 × 512 + 64 = 17 472 samples at this node.

Reference: **LPSCPHY_MCS26_Payload Samples.txt**

I.7.5 DMG low-power SC mode MCS 30 payload

I.7.5.1 Payload bits

Figure I-8 node ①. The payload at node is a count, modulo 256, starting at 0.

For MCS 30, the DMG low-power SC mode payload padding calculation gives $N_{DATA\_PAD} = 472$; however, unlike the other modes, this padding data is not appended before FEC computation.

So there are just 1000 × 8 = 8000 payload bits.

Reference: **LPSCPHY_MCS30_Payload bits.txt**

I.7.5.2 Scrambled payload bits

Figure I-8 node ②. All 8000 bits are scrambled according to a scrambler initialization value of 66.

Reference: **LPSCPHY_MCS30_Scrambled Payload bits.txt**

I.7.5.3 RS(224,208) encoded payload bits

Figure I-8 node ③. In this example, there are 4 RS(224,208) codewords and one shortened RS(184,168) codeword, giving a total of (4 × 224 + 1 × 184) × 8 = 8 640 bits at this node.

Reference: **LPSCPHY_MCS30_RS(224,208) Output bits.txt**

I.7.5.4 Spc(9,8) block coded payload bits

Figure I-8 node ④. The (9,8) block coder increases the effective bits from 8 640 to 9 720.

Reference: **LPSCPHY_MCS30_Block Coded Payload bits.txt**

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

I.7.5.5 Interleaved payload bits

Figure I-8 node ⑤. Before interleaving the block coder output is padded with $N_{DATA\_PAD} = 472$ scrambled zeros to give 10 192 bits (26 × 392). The interleaver then redistributes these bits in time, as specified.

Reference: **LPSCPHY_MCS30_RS Encoded and Interleaved Payload bits.txt**

I.7.5.6 Payload samples

Figure I-8 node ⑥. Each block of 784 bits from the interleaver output is QPSK mapped to 392 modulation symbols, prepended with a Ga_{64} sequence as a guard interval and punctuated by G_8 (last 8 samples of Ga_{64}) guard intervals, then π/2 rotated, thus resulting in a 512 symbol π/2-BPSK modulation block.

In this example, there are 13 modulation blocks and, as specified, the last one is followed by a terminating Ga_{64} guard interval sequence, so there are 13 × 512 + 64 = 6 720 samples at this node.

Reference: **LPSCPHY_MCS30_Payload Samples.txt**

I.8 EDMG example data vectors

Encoding examples are provided for the FORMAT parameter set to EDMG and the EDMG_MODULATION parameter set to EDMG_C_MODE or EDMG_SC_MODE. Encoding examples for the EDMG_OFDM_MODE are not provided.

Encoding examples are contained in the EDMGEncodingExamples.zip file embedded into the IEEE 802.11 Working Group document 11-18/1346r0, located at https://mentor.ieee.org/802.11/documents?is_dcn=1346&is_group=00ay. The specified document provides the detailed description of the input and output interfaces as well as the modes that were tested.

The EDMGEncodingExamples.zip contains three types of files:

— "PSDU.txt" – the TXT-file containing a time ordered sequence of 1 and 0 digits, separated by commas. It contains PSDU payload bit content used in all configuration modes.

— "*.xlsx" – the XLSX-file containing the configuration parameters for given mode of operation. The file represents an XL table with fields used to configure the PPDU transmission. Each field is represented in the decimal notation with bit precision defined in the EDMG PHY. The field names are aligned with the ones used in the TX/RXVECTOR and PHY headers.

— "*.mat" – the MATLAB MAT-file containing the output encoded and modulated PPDU. The file names for the MAT-files are identical to the XLSX-files to which they are coupled. The MAT-file contains a time ordered sequence of complex symbols, formatted as ±<real>±<imag>*j* with double floating point precision.

For EDMG_C_MODE and EDMG_SC_MODE, the spectrum shaping filter is not applied to the output PPDU and it is defined at the original chip rate. The shaping filter is not defined in the EDMG PHY and is implementation dependent.

For EDMG_C_MODE, the Preamble and Data fields are defined at the chip rate $F_c = 1.76$ GHz and the TRN field (if present) is defined at the chip rate $F_{c\ EDMG} = 1.76 \times N_{CB}$ GHz, where N_{CB} defines the number of contiguous 2.16 GHz channels. For EDMG_SC_MODE, the pre-EDMG modulated fields are defined at the chip rate $F_c = 1.76$ GHz and the EDMG modulated fields are defined at the chip rate $F_{c\ EDMG} = 1.76 \times N_{CB}$ GHz.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The TXT, XLSX, and MAT-files can be read using the standard MATLAB dlmread(), xlsread(), and load() functions respectively. To convert the cell array into the ordinary array and to the char array, the standard MATLAB cell2mat() and char() functions can be used.

Annex J

(informative)

RSNA reference implementations and test vectors

J.1 TKIP temporal key mixing function reference implementation and test vector

J.1.1 TKIP temporal key mixing function reference implementation

This clause provides a C-language reference implementation of the temporal key mixing function.

```
*   The purpose of this routine is solely to illustrate and
*   verify the following properties of the Sbox table:
*      - the Sbox is a "2×2" subset of the AES table:
*            Sbox + affine transform + MDS.
*      - the Sbox table can be easily designed to fit in a
*            512-byte table, using a byte swap
*      - the Sbox table can be easily designed to fit in a
*            256-byte table, using some shifts and a byte swap
**********************************************************************

/*
*****************************************************************
* Routine: Phase 2 -- generate ARC4KEY, given TK, P1K, IV16
*
* Inputs:
*     TK[]      = Temporal Key                        [128 bits]
*     P1K[]     = Phase 1 output key                  [ 80 bits]
*     IV16      = low 16 bits of IV counter           [ 16 bits]
* Output:
*     ARC4KEY[]  = the key used to encrypt the frame  [128 bits]
*
* Note:
*     The value {TA,IV32,IV16} for Phase1/Phase2 shall be unique
*     across all frames using the same key TK value. Then, for a
*     given value of TK[], this TKIP48 construction guarantees that
*     the final ARC4KEY value is unique across all frames.
*
* Suggested implementation optimization: if PPK[] is "overlaid"
*     appropriately on ARC4KEY[], there is no need for the final
*     for loop below that copies the PPK[] result into ARC4KEY[].

J.2 Michael reference implementation and test vectors

J.2.1 Michael test vectors

J.2.1.1 Introduction

Test vectors are provided below in order to support correct implementation of michael. These test vectors still have to be confirmed by an independent implementation.

J.2.1.2 Block function

Table J-1 gives some test vectors for the block function.

Table J-1—Test vectors for block function

Input	# times	Output
(00000000, 00000000)	1	(00000000, 00000000)
(00000000, 00000001)	1	(c00015a8, c0000b95)
(00000001, 00000000)	1	(6b519593, 572b8b8a)
(01234567, 83659326)	1	(441492c2, 1d8427ed)
(00000001, 00000000)	1000	(9f04c4ad, 2ec6c2bf)

The first four rows give test vectors for a single application of the block function *b*. The last row gives a test vector for 1000 repeated applications of the block function. Together these should provide adequate test coverage.

J.2.1.3 Michael

Table J-2 gives some test vectors for michael.

Table J-2—Test vectors for michael

Key	Message	Output
0000000000000000	""	82925c1ca1d130b8
82925c1ca1d130b8	"M”	434721ca40639b3f

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table J-2—Test vectors for michael

Key	Message	Output
434721ca40639b3f	"Mi “	e8f9becae97e5d29
E8f9becae97e5d29	"Mic"	90038fc6cf13c1db
90038fc6cf13c1db	"Mich"	D55e100510128986
D55e100510128986	"Michael"	0a942b124ecaa546

Note that each key is the result of the previous line, which makes it easy to construct a single test out of all of these test cases.

J.2.2 Sample code for michael

```
//
// Michael.h    Reference implementation for michael

//
// A michael object implements the computation of the MIC.
//
// Conceptually, the object stores the message to be authenticated.
// At construction the message is empty.
// The append() method appends bytes to the message.
// The getMic() method computes the MIC over the message and returns the
// result.
// As a side-effect it also resets the stored message
// to the empty message so that the object can be reused
// for another MIC computation.

class Michael
{

public:
    // Constructor requires a pointer to 8 bytes of key
    Michael( Byte * key );

    // Destructor
    ~Michael();

    // Clear the internal message,
    // resets the object to the state just after construction.
    void clear();

    // Set the key to a new value
    void setKey( Byte * key );
```

J.4 Suggested pass-phrase-to-PSK mapping

J.4.1 Introduction

The RSNA PSK consists of 256 bits, or 64 octets when represented in hexadecimal. It is difficult for a user to correctly enter 64 hexadecimal characters. Most users, however, are familiar with passwords and pass-phrases and feel more comfortable entering them than entering keys. A user is more likely to be able to enter an ASCII password or pass-phrase, even though doing so limits the set of possible keys. This suggests that the best that can be done is to introduce a pass-phrase to PSK mapping.

This subclause defines a pass-phrase–to–PSK mapping that is the recommended practice for use with RSNAs. This pass-phrase mapping was introduced to encourage users unfamiliar with cryptographic concepts to enable the security features of their WLAN.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Keys derived from the pass-phrase provide relatively low levels of security, especially with keys generated form short passwords, since they are subject to dictionary attack. Use of the key hash is recommended only where it is impractical to make use of a stronger form of user authentication. A key generated from a pass-phrase of less than about 20 characters is unlikely to deter attacks.

The pass-phrase mapping defined in this subclause uses the PBKDF2 as defined in IETF RFC 2898 [B34] section 5.2.

PSK = PBKDF2(*passPhrase*, *ssid*, 4096, 256/8)

The following apply:

— passPhrase is a sequence of between 8 and 63 ASCII-encoded characters. The limit of 63 comes from the need to distinguish between a pass-phrase and a PSK displayed as 64 hexadecimal characters.
— Each character in the pass-phrase has an encoding in the range 32 to 126 (decimal).
— *ssid* is the SSID of the ESS or IBSS where this pass-phrase is in use, encoded as an octet string used in the Beacon and Probe Response frames for the ESS or IBSS.
— 4096 is the number of times the pass-phrase is hashed.
— 256 is the number of bits output by the pass-phrase mapping.

J.4.2 Test vectors

```
Test case 1
passPhrase = "password"
ssid = { 'I', 'E', 'E', 'E' }
PSK = f42c6fc52df0ebef9ebb4b90b38a5f90 2e83fe1b135a70e23aed762e9710a12e

Test case 2
passPhrase = "ThisIsAPassword"
ssid = { 'T', 'h', 'i', 's', 'I', 's', 'A', 'S', 'S', 'I', 'D' }
PSK = 0dc0d6eb90555ed6419756b9a15ec3e3 209b63df707dd508d14581f8982721af

Test case 3
passPhrase = "aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa"
ssid = {'Z','Z','Z','Z', 'Z','Z','Z','Z', 'Z','Z','Z','Z', 'Z','Z','Z','Z',
             'Z','Z','Z','Z', 'Z','Z','Z','Z', 'Z','Z','Z','Z', 'Z','Z','Z','Z'}
PSK = becb93866bb8c3832cb777c2f559807c 8c59afcb6eae734885001300a981cc62
```

Note that the passPhrase does not have a terminating null.

J.5 Suggestions for random number generation

J.5.1 General

In order to properly implement cryptographic protocols, every platform needs the ability to generate cryptographic-quality random numbers. IETF RFC 4086 explains the notion of cryptographic-quality random numbers and provides advice on ways to harvest suitable randomness. It recommends sampling multiple sources, each of which contains some randomness, and by passing the complete set of samples through a PRF. By following this advice, an implementation can usually collect enough randomness to distill into a seed for a PRNG whose output is unpredictable.

This clause suggests two sample techniques that can be combined with the other recommendations of IETF RFC 4086 to harvest randomness. The first method is a software solution that can be implemented on most

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

hardware; the second is a hardware-assisted solution. These solutions are expository only, to demonstrate that it is feasible to harvest randomness on any IEEE 802.11 platform. They are not mutually exclusive, and they do not preclude the use of other sources of randomness when available, such as a noisy diode in a power circuit; in this case, the more the merrier. As many sources of randomness as possible should be gathered into a buffer, and then hashed, to obtain a seed for the PRNG.

J.5.2 Software sampling

Due to the nature of clock circuits in modern electronics, there is some lack of correlation between two clocks in two different pieces of equipment, even when high-quality crystals are used—crystal clocks are subject to jitter, noise, drift, and frequency mismatch. This randomness might be as little as the placement of the clock waveform edges. Even if one entity were to attempt to synchronize itself to another entity's clock, the correlation cannot be perfect due to noise and uncertainties of the synchronization.

Two clock circuits in the same piece of equipment might synchronize in frequency, but again the correlation is not perfect due to the noise and jitter of the circuits.

The randomness between the two clocks might not be much per sample—a tenth of a bit or less—but enough samples might be collected to gather enough randomness to form a seed.

A device can use software methods to take advantage of this lack of synchronization, to collect randomness from different sources. As an example, an AP might measure the frame arrival times on Ethernet wireless ports. There is always some amount of traffic on modern Ethernets: ARPs, DHCP requests, NetBIOS advertisements, etc. The sample algorithm in this subclause uses this traffic. In the example, an AP obtains randomness from the available traffic. If Ethernet traffic is available, the AP utilizes that for a source of randomness. Otherwise, it waits for the first association and creates traffic from which it can obtain randomness.

The clocks used to time the frames should be the highest resolution available, preferably 1 ms resolution or better. The clock used to time frame arrival should not be related to the clock used for frame serialization.

```
Initialize result to empty array
LoopCounter = 0
Wait until Ethernet traffic or association
Repeat until global key counter "random enough" or 32 times {
    result = PRF-256(0, "Init Counter",
    Local MAC Address || Time || result || LoopCounter)
    LoopCounter++
    Repeat 32 times {
        If Ethernet traffic available then {
            Take least significant octet of the timestamp when Ethernet packet is received
            Concatenate this octet onto result
        } else {
            Start 4-way handshake; after receipt of message 2, deauthenticate
            Take least significant octet of the timestamp of when message 1 is sent
            Take least significant octet of the timestamp of when message 2 is received
            Take the least significant octet of RSSI from message 2
            Take SNonce from message 2
            Concatenate the sent time, received time, RSSI and SNonce octets onto result
        }
```

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

```
        }
    }
    Global key counter = result = PRF-256(0, "Init Counter",
    Local MAC Address || Time || result || LoopCounter)
```

NOTE—The Time is set to 0 if it is not available.

J.5.3 Hardware-assisted solution

The sample implementation in this subclause uses hardware ring oscillators to generate randomness, as depicted in Figure J-1.

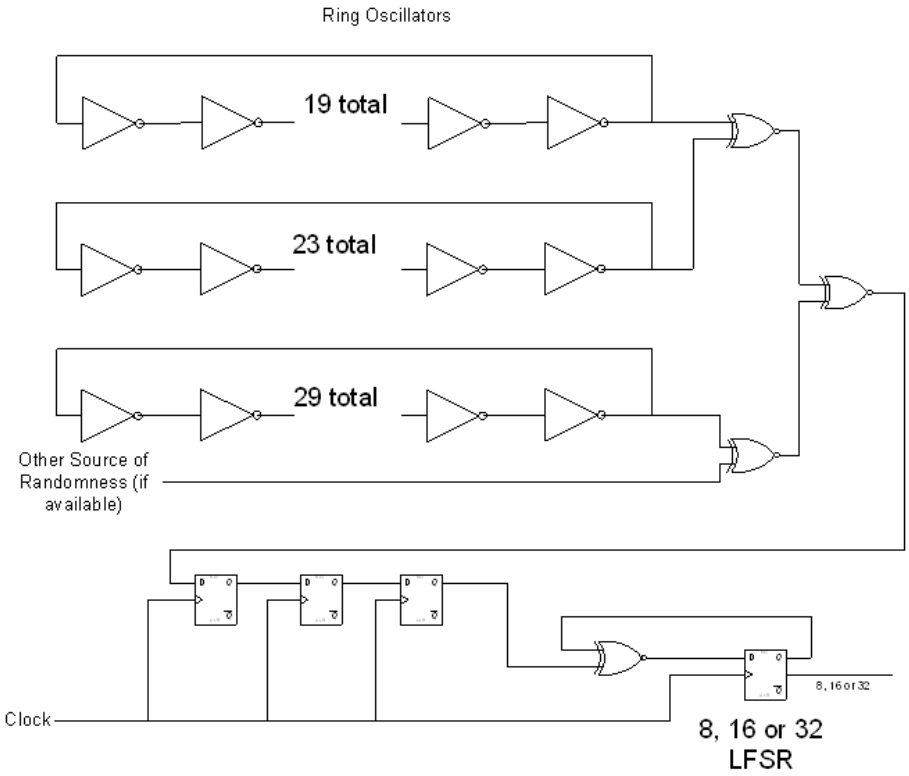

Figure J-1—Randomness generating circuit

The circuit in Figure J-1 generates randomness. The clock input should be about the same frequency as the ring oscillator's natural frequencies. The LFSR should be chosen to be one that is maximal length. Sample LFSRs can be found in Arazi [B4].

The three ring oscillators should be isolated from each other as much as possible to avoid harmonic locking between them. In addition, the three ring oscillators should not be near any other clock circuitry within the system to avoid these ring oscillators locking to system clocks. The oscillators should be tested to verify that their output is not correlated.

The output of the LFSR is read by software and concatenated until enough randomness is collected. As a rule of thumb, reading from the LFSR 8 to 16 times the number of bits as the desired number of random bits is sufficient.

```
Initialize result to empty array
Repeat 1024 times {
      Read LFSR
      result = result | LFSR
      Wait a time period
}
Global key counter = PRF-256(0, "Init Counter", result)
```

J.6 Additional test vectors

J.6.1 Notation

In the examples that follow in J.6, frames are represented as a stream of octets, each octet in hexadecimal notation, sometimes with text annotation. The order of transmission for octets is left to right, top to bottom. For example, consider the following representation of a frame in Table J-3.

Table J-3—Notation example

Description #1	00 01 02 03 04 05
Description #2	06 07 08

The frame consists of 9 octets, represented in hexadecimal notation as “00”, “01”, ..., “08”. The octet represented by “00” is transmitted first, and the octet represented by “08” is transmitted last. Similar tables are used for other purposes, such as describing a cryptographic operation.

J.6.2 TKIP test vector

An example of a TKIP MSDU is provided in Table J-4 and Table J-5. The key and PN are used to create the IV, Phase1, and Phase2 keys.

Table J-4—Sample TKIP parameters

J.6.4 PRF test vectors

A set of test vectors are provided for each size of PRF function used in this subclause. See Table J-6 to Table J-9. The inputs to the PRF function are strings for key, prefix, and data. The length can be any multiple of 8, but the values 192, 256, 384, and 512 are used in this subclause. The test vectors were taken from IETF RFC 2202 [B25] with additional vectors added to test larger key and data sizes.

J.7 Key hierarchy test vectors for pairwise keys

J.7.1 General

The test vectors in this subclause provide an example of PTK derivation for both CCMP-128 and TKIP.

Pairwise keys are derived from the PMK, AA, SPA, SNonce, and ANonce. The values in Table J-10 are used as input to the pairwise key derivation test vectors.

Table J-10—Sample values for pairwise key derivations

PMK	0d c0 d6 eb 90 55 5e d6 41 97 56 b9 a1 5e c3 e3 20 9b 63 df 70 7d d5 08 d1 45 81 f8 98 27 21 af
AA	a0 a1 a1 a3 a4 a5
SPA	b0 b1 b2 b3 b4 b5
SNonce	c0 c1 c2 c3 c4 c5 c6 c7 c8 c9 d0 d1 d2 d3 d4 d5 d6 d7 d8 d9 da db dc dd de df e0 e1 e2 e3 e4 e5
ANonce	e0 e1 e2 e3 e4 e5 e6 e7 e8 e9 f0 f1 f2 f3 f4 f5 f6 f7 f8 f9 fa fb fc fd fe ff 00 01 02 03 04 05

J.7.2 CCMP-128 pairwise key derivation

Using the values from Table J-10 for PMK, AA, SPA, SNonce, and ANonce, the key derivation process for CCMP generates a temporal key as shown in Table J-11.

Table J-11—Sample derived CCMP-128 temporal key (TK)

TK	b2 36 0c 79 e9 71 0f dd 58 be a9 3d ea f0 65 99

J.7.3 TKIP pairwise key derivation

Using the values from Table J-10 for PMK, AA, SPA, SNonce, and ANonce, the key derivation process for TKIP generates the values shown in Table J-12.

Table J-12—Sample derived PTK

PTK-KCK	37 9f 98 52 d0 19 92 36 b9 4e 40 7c e4 c0 0e c8

J.12 PASN Test Vectors

The Diffie-Hellman exchange to establish a shared secret used in key derivation for PASN and FILS with PFS is a well known algorithm. See IETF RFC 5903 [B48] for test vectors when using ECP groups. Only the x-coordinate of the result of scalar multiplication of a private key with the received public key is used as the shared secret.

Annex K

(informative)

TSPECs and admission control

K.1 Example use of TSPEC for admission control

Admission control, in general, depends on vendors' implementations of schedulers, available channel capacity, link conditions, retransmission limits, and the scheduling requirements of a given TSPEC. However, for any given channel capacity, link conditions, and retransmission limits, some TSPEC constructions might be categorically rejected because a scheduler cannot create a meaningful schedule for that TSPEC. There needs to be, for example, be a minimum number of specified fields in the TSPEC in order for the admission control mechanism to create a valid TSPEC. Table K-1 below lists the valid TSPEC fields that need to be present for all admission control algorithms to admit a TSPEC. This represents a set of necessary parameters in order for TSPEC to be admitted; it is not sufficient in and of itself to guarantee TSPEC admittance, which depends upon channel conditions and other factors. Such TSPECs are said to be *admissible*. In the table, S means specified, X means unspecified, and Opt means "optional."

Table K-1—Admissible TSPECs

TSPEC parameter	Continuous time QoS traffic (HCCA)	Controlled-access CBR traffic (HCCA)	Bursty traffic (HCCA)	Contention based traffic (EDCA)
Nominal MSDU Size	S	S	X	S
Minimum Service Interval	S	Nominal MSDU size/mean data rate, if specified (VoIP typically uses this)	S Usually set to 0 or a small number (e.g., 1)	X
Maximum Service Interval	S	Same as Minimum SI	S	Opt (Used to indicate aggregation limit)
Inactivity Interval	Always specified			X
Suspension Interval	Opt			
Minimum Data Rate	Specified if peak data rate is specified	Equal to mean data rate	X	Specified if peak data rate is specified
Mean Data Rate	S	S	Opt	S
Burst Size	X	X	S	Opt
Minimum PHY Rate	Always specified			
Peak Data Rate	Opt Should be specified if Minimum Data Rate is specified	Equal to Mean Data Rate	Opt	Opt Should be specified if Minimum Data Rate is specified

Table K-1—Admissible TSPECs *(continued)*

TSPEC parameter	Continuous time QoS traffic (HCCA)	Controlled-access CBR traffic (HCCA)	Bursty traffic (HCCA)	Contention based traffic (EDCA)
Delay Bound	S	S	Opt	Opt
Surplus Bandwidth Allow-ance	Is specified if the delay bound is present			S
Medium Time	(not specified by non-AP STA; only an output from the HC)			

K.2 Recommendation for implementation of contention based admission control

K.2.1 Use of ACM (admission control mandatory) subfield

It is recommended that admission control not be required for the access categories AC_BE and AC_BK. The ACM subfield for these categories should be set to 0. The announced EDCA parameters and the EDCA parameters used by the AP should account for unadmitted traffic in these ACs.

When dot11SSPNInterfaceActivated is true, it is recommended that any STA authenticated through an SSPN interface use admission control to access categories AC_VO and AC_VI to produce network utilization consistent with the policy imposed by the SSPN for admission. The announced EDCA parameters and the EDCA parameters used by the AP should further account for any unadmitted traffic in AC_VO and AC_VI that might be reserved for users of a particular SSPN.

K.2.2 Deriving medium time

An AP should use the following procedure to derive the value of the Medium Time field in its ADDTS Response frame.

There are two requirements to consider: 1) the traffic requirements of the application, and 2) the expected error performance of the medium.

The application requirements are captured by the following TSPEC fields: Nominal MSDU Size and Mean Data Rate. Note that the Nominal MSDU Size field is the nominal A-MSDU size, where A-MSDU aggregation is employed.

The medium requirements are captured by the following TSPEC fields: Surplus Bandwidth Allowance and Minimum PHY Rate.

The following formula describes how Medium Time, in units of 32 μs periods per second, can be calculated:

$$\text{Medium Time} = \left\lceil \frac{\text{Surplus Bandwidth Allowance} \times \text{Packets Per Second} \times \text{Frame Exchange Time}}{0\text{x}2000 \times 32} \right\rceil$$

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

where

a) if A-MPDU aggregation is not employed (i.e., TS Info Ack Policy = 00 (Normal Acknowledgment)):

$$\text{Packets Per Second} = \left\lceil \frac{\text{Mean Data Size}}{8 \times \text{Nominal MSDU Size}} \right\rceil$$

Frame Exchange Time =
duration (Nominal MPDU Size, Minimum PHY Rate)
+ SIFS
+ duration (Ack Size, Ack Rate)

Nominal MPDU Size =
MAC Header Size
+ Nominal MSDU Size
+ Security Encapsulation Size
+ FCS Size

b) if A-MPDU aggregation is employed (i.e., TS Info Ack Policy = 11 (Block Ack)):

$$\text{Packets Per Second} = \left\lceil \frac{\text{Mean Data Rate}}{8 \times \text{Nominal MSDU Size} \times \text{Nominal MSDUAggregation}} \right\rceil$$

Frame Exchange Time =
duration (Nominal A-MPDU Size, Minimum PHY Rate)
+ SIFS
+ duration (BlockAck Size, BlockAck Rate)

Nominal A-MPDU Size =
Nominal MSDU Aggregation
× Nominal A-MPDU Subframe Size
– Padding Size

Nominal A-MPDU Subframe Size =
MPDU Delimiter Size
+ MAC Header Size
+ Nominal MSDU Size
+ Security Encapsulation Size
+ FCS Size
+ Padding Size

Padding Size =
3
– (MAC Header Size
+ Nominal MSDU Size
+ Security Encapsulation Size
+ 3)
mod 4

and where

Sizes are in octets; Rates are in b/s; durations and Times are in μs; Surplus Bandwidth Allowance is the unsigned integer value passed

MAC Header Size = 26

MPDU Delimiter Size = 4

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Security Encapsulation Size = 16 (CCMP), 20 (GCMP and TKIP), or 0 (open system)
Ack Size = 14
BlockAck Size = 32
FCS Size = 4
SIFSIFS = 10 when operating in the 2.4 GHz band, 16 when operating in the 5 GHz band, 3 when operating in the 60 GHz band
Ack/BlockAck Rate is the rate used for the Ack/BlockAck frame, given the Minimum PHY Rate, subject to the corresponding multirate rules
duration () is the PLME-TXTIME primitive defined in 6.7.5 and 6.7.6 that returns the duration of a PPDU based on the PSDU size and the PHY data rate and PHY employed, e.g., 16.3.4, 17.4.3, 18.5.3.2, 19.4.3, and 20.11.3

Notes:

— Division does not truncate.

— Any signal extension is included, even for the signal extension following the PPDU containing the acknowledgment frame which ends the frame exchange.

— If protection frames are used, then they are included in the Frame Exchange Time too. Each frame contributes an additional term:

Frame Exchange Time +=
duration (Protection Frame Size, Protection Frame Rate)
+ SIFS

where
RTS Protection Frame Size = 20
CTS Protection Frame Size = 14
Protection Frame Rate is the rate used for the protection frame, given the Minimum PHY Rate, subject to the corresponding multirate and protection rules

An AP assumes that a STA will use CTS-to-self protection if an ERP element directs use of protection.

— The assumption is made that HT Control headers and beamforming frames are not normally used and so their contribution to Medium Time is negligible.

— The Nominal A-MPDU Subframe Size can be increased by the AP where necessary to account for the Minimum MPDU Start Spacing. For example, if the Minimum PHY Rate is 65 Mb/s and the Minimum MPDU Start Spacing is 16 μs then the minimum Nominal A-MPDU Subframe Size is 132 octets (including 2 octets of pad).

— A STA might request TSPEC fields that would result in violation of other applicable constraints such as the receiver's maximum A-MSDU or A-MPDU size, any maximum PPDU duration, or, for uplink or bidirectional TSPECs, any nonzero TXOP limit. An AP receiving such a request is likely to reject it. An AP might also reject requests that cannot be satisfied for reasons that the STA is not always aware of, such as, for uplink or bidirectional TSPECs, the AP's maximum Block Ack Buffer Size.

— Where A-MPDU aggregation is employed, HT-immediate block ack is assumed.

K.3 Guidelines and reference design for sample scheduler and admission control unit

K.3.1 Guidelines for deriving service schedule parameters

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The HC establishes the SI for each admitted TS for a STA to derive the aggregate minimum SI contained in the STA's service schedule. The SI for each TS is equal to the maximum SI contained in the TSPEC, if it exists; otherwise, it is the nominal MSDU size divided by the mean data rate. The SI contained in the service schedule is equal to the smallest SI for any TSPEC.

The HC can use an aggregate "token bucket specification" to police a STA's admitted flows. The HC derives the aggregate mean data rate and aggregate burst size to establish the aggregate token bucket specification. The aggregate mean data rate is equal to the sum of the mean data rates of all of the STA's admitted TSs. The aggregate burst size is equal to the sum of the burst size of all of the STA's admitted TSs. An aggregate token bucket is initialized with the aggregate burst size. Tokens are added to the token bucket at the aggregate mean data rate. Alternatively the method of summing TSPECs for statistical multiplexing, as described in T.2.3, can be used.

When dot11SSPNInterfaceActivated is true, the HC polices all traffic flows from a non-AP STA authenticated against the maximum authorized data rates stored in the dot11InterworkingTable. Each SSPN-authenticated STA is given a maximum bandwidth allowance by the SSPN for each access category as well as scheduled access. The AP polices the SSPN-authenticated STA traffic flows to the maximum bandwidth allowance provided by the SSPN.

K.3.2 Reference design for sample scheduler and admission control unit

K.3.2.1 General

This subclause provides the guidelines for the design of a simple scheduler and admission control unit (the unit that administers admission policy in the HC's SME) that meet the minimum performance requirements as specified in 10.23.4.3. The scheduler and admission control unit use the minimum set of mandatory TSPEC fields as specified in 10.23.4.3.

K.3.2.2 Sample scheduler

This subclause includes the reference design for a sample scheduler. This scheduler uses the mandatory set of TSPEC fields to generate a schedule: Mean Data Rate, Nominal MSDU Size, and Maximum Service Interval or Delay Bound. If both Maximum Service Interval and Delay Bound parameters are specified in the TSPEC, the scheduler uses the Maximum Service Interval parameter for the calculation of the schedule.

The schedule generated by the scheduler satisfies the requirements specified in 10.23.4.3. The schedule for an admitted stream is calculated in two steps. The first step is the calculation of the scheduled SI. In the second step, the TXOP duration for a given SI is calculated for the stream.

The calculation of the scheduled service interval is done as follows: First, the scheduler calculates the minimum of all maximum SIs for all admitted streams. Let this minimum be *m*. Second, the scheduler chooses a number lower than *m* that is a submultiple of the beacon interval. This value is the scheduled SI for all STAs with admitted streams. See Figure K-1.

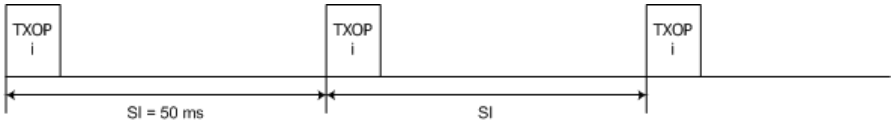

Figure K-1—Schedule for stream from STA *i*

For the calculation of the TXOP duration for an admitted stream, the scheduler uses the following parameters: Mean Data Rate and Nominal MSDU Size; and from the negotiated TSPEC, the Scheduled

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Service Interval calculated above, Physical Transmission Rate, Maximum Allowable Size of MSDU, and Overhead. The Physical Transmission Rate is the minimum PHY rate negotiated in the TSPEC. If the minimum PHY rate is not committed in the ADDTS Response frame, the scheduler can use the observed PHY rate as the Physical Transmission Rate. The Overhead includes IFSs, Ack frames and QoS CF-Poll frames. For simplicity, details for the Overhead calculation are omitted in this description. The TXOP duration is calculated as follows: First, the scheduler calculates the number of MSDUs that can arrive at the Mean Data Rate during the SI:

$$N_i = \left\lceil \frac{SI \times \rho_i}{L_i} \right\rceil$$

where

SI is the Scheduled Service Interval
ρ is the Mean Data Rate
L is the Nominal MSDU Size

Then the scheduler calculates the TXOP duration as the maximum of

— Time to transmit N_i frames at R_i and
— Time to transmit one maximum size MSDU at R_i (plus overhead):

$$TXOP_i = max(\frac{N_i \times L_i}{R_i} + O, \frac{M}{R_i} + O)$$

where

R is the Physical Transmission Rate
M is the maximum possible size of MSDU
O is the Overhead in time units

An example is shown in Figure K-1. Stream from STA *i* is admitted. The beacon interval is 100 ms and the maximum SI for the stream is 60 ms. The scheduler calculates a scheduled SI (SI) equal to 50 ms using the steps explained above is this annex.

The same process is repeated continuously while the maximum SI for the admitted stream is larger than the current SI. An example is shown in Figure K-2.

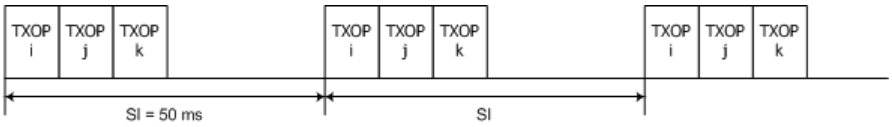

Figure K-2—Schedule for streams from STAs *i* to *k*

If a new stream is admitted with a maximum SI smaller than the current SI, the scheduler needs to change the current SI to a smaller number than the maximum SI of the newly admitted stream. Therefore, the TXOP duration for the current admitted streams needs also to be recalculated with the new SI.

If a stream is dropped, the scheduler might use the time available to resume contention. The scheduler might also choose to move the TXOPs for the STAs following the STA dropped to use the unused time. An example is shown in Figure K-3, when the stream for STA *j* is removed. However, this option might require the announcement of a new schedule to all STAs.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Figure K-3—Reallocation of TXOPs when a stream is dropped

Different modifications can be implemented to improve the performance of the minimum scheduler. For example, a scheduler might generate different scheduled SIs (SI) for different STAs, and/or a scheduler might consider accommodating retransmissions while allocating TXOP durations.

K.3.2.3 Admission control unit

This subclause describes a reference design for an admission control unit (ACU) that administers admission of TS. The ACU uses the same set of parameters that the scheduler uses in K.3.2.2.

When a new stream requests admission, the admission control process is done in three steps. First, the ACU calculates the number of MSDUs that arrive at the mean data rate during the scheduled SI. The scheduled SI (SI) is the one that the scheduler calculates for the stream as specified in K.3.2.2. For the calculation of the number of MSDUs, the ACU uses the equation for N_i shown in K.3.2.2. Second, the ACU calculates the TXOP duration that needs to be allocated for the stream. The ACU uses the equation for $TXOP_i$ shown in K.3.2.2. Finally, the ACU determines that the stream can be admitted when the following inequality is satisfied:

$$\frac{TXOP_{k+1}}{SI} + \sum_{i=1}^{k} \frac{TXOP_i}{SI} \leq \frac{T - T_{EDCA}}{T}$$

where

k is the number of existing streams
$k + 1$ is used as index for the newly arriving stream
T indicates the beacon interval
T_{EDCA} is the time used for EDCA traffic

Subclause 10.23.3.3 requires that the ACU complies with the dot11CAPlimit, i.e., the scheduler does not allocate TXOPs that exceed dot11CAPlimit. The ACU might also consider additional time to allow for retransmissions.

The ACU allows admitted streams to have an allocated access to the channel. Any modification can be implemented for the design of the ACU. For example, UP-based ACU is possible by examining the UP field in TSPEC to decide whether to admit, retain, or drop a stream. If the UP is not specified, a default value of 0 is used. If a higher UP stream needs to be serviced, an ACU might drop lower UP streams.

K.4 TSPEC construction

K.4.1 General

TSPECs are constructed at the SME from application requirements supplied via the SME and with information specific to the MAC. However, in this subclause a description is given of how and where certain parameters can be chosen. The following parameters typically arise from the application: Nominal MSDU

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Size, Maximum MSDU Size, Minimum Service Interval, Maximum Service Interval, Inactivity Interval, Minimum Data Rate, Mean Data Rate, Burst Size, Peak Data Rate, and Delay Bound. The following parameters are generated locally within the MAC: Minimum PHY Rate and Surplus Bandwidth Allowance, although the Maximum Service Interval and Minimum Service Intervals can be generated within the MLME as well. This subclause describes how the parameters that are typically generated within the MAC can be derived.

Note that a TSPEC can also be generated autonomously by the MAC without any initiation by the SME. However, if a TSPEC is generated subsequently by the SME, the TSPEC generated autonomously by the MAC might be overridden (see 11.4.4.5).

Typically, TSPEC fields not determined by the application are built upon the assumption that the following exist:

— A probability p of not transmitting the frame (because it would have exceeded its delay bound)
— An MSDU length (which can be considered fixed for constant-bit-rate applications)
— Application throughput and delay requirements
— A channel model of error, in particular a channel error probability for the (fixed) frame length
— Possibly country-specific limits on TXOP limits

K.4.2 Surplus Bandwidth Allocation

Typically, it can be assumed that the scheduler would attempt to schedule TXOPs distributed throughout a small multiple of beacon intervals (if not a single beacon interval). In addition, TXOP limits would typically be chosen to be as short as possible (within the constraints of the minimum PHY rate, ack policy, and so forth), consistent with the goal of maximizing throughput. In other words, because of overhead, not to mention the requirements for transmitting a single Poll frame, MPDU, and possibly Ack frame, the TXOPs need to be at least of a certain duration.

The channel model implies an error ratio and an assumption about dependency (joint probability distribution of channel errors sequentially, i.e., burst error probabilities).

For example, if the channel causes errors independently from frame to frame and the error probability is the same for all frames of the same length at all times, this channel would be said to be an independent, identically distributed error channel. Let N_p be the minimum number of retries required to maintain the probability of abandoning the transmission of the frame to be no more than p, and let p_e be the probability of the frame not being transmitted successfully in a given frame exchange (i.e., either the Data frame or the Ack frame associated with it is in error).

The probability of any given packet being abandoned in such a channel after N_p retries is given by

$$p_{\text{ignore}} = (p_e)^{N_p + 1}$$

For example, in such a channel, if $p_e = 0.1$ and $p_{\text{ignore}} = 10^{-8}$, then up to seven retries within the delay bound are required, and the scheduler should consider these retransmissions in the cumulative TXOP allocations.

The Surplus Bandwidth Allowance (SBA) parameter causes the requesting STA to be allocated a minimum amount of excess time by the scheduler so that the application abandoned packet rates are bounded.

The probability of not successfully transmitting k packets is given by the cumulative distribution function of the Binomial Distribution.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The binomial probability mass function is

$$b(k, n, p) = \frac{n!}{k!(n-k)!} p^k (1-p)^{n-k}$$

where

n is the number of trials
p is the probability of success for each trial.

The binomial cumulative distribution function is

$$B(k, n, p) = \sum_{y=0}^{n} b(y, n, p)$$

Assuming a certain packet error ratio (PER), P_e, the number of extra packets, N, that are required in order to have a probability, P_{ns}, of not successfully transmitting S packets is given:

$$B(S, S+N, 1-P_e) = \sum_{y=0}^{n} b(y, S+N, 1-P_e)$$

Then

$SBA = (S+N)/S$

Now, if just one packet is lost, then the lost packet ratio, L_{PR}, is $L_{PR} = 1/(S+N)$

The condition where $P_{ns} < L_{PR}$ represents a practical point for determining the value of N.

Medium Time used for EDCA Admission Control is based upon one second periods and HCCA Medium time, used to aggregate TSPECs (see T.2.3) also uses the one second period. Hence, for each application, S is the number of packets that are desired to be sent in each one second period.

For example, consider a voice application:

PER, $P_e = 0.1$ or probability of success is $1 - P_e = 0.9$

Number of packets per second, $S = 50$

Probability of not having 50 successful packets, $P_{ns} = 0.87\%$ for $N = 13$

Lost packet ratio for 1 lost packet, $L_{PR} = 1.59\%$

$SBA = 1.26$

Take the example of a video stream at 380 packets per second (about 4 Mb/s):

Number of packets per second, $S = 380$

Probability of not having 380 successful packets, $P_{ns} = 0.2\%$ for $N = 64$

Lost packet ratio for 1 lost packet, $L_{PR} = 0.23\%$

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

$SBA = 1.168$

It can be seen that the value for SBA varies with *S*, the number of required packets per second.

A reasonable estimate for *SBA* is given by

$SBA = -0.033 \ln(S) + 1.37$

Table K-2 is a table of *SBA* for various values of *S*, and the *SBA* estimate derived by using the formula above.

Table K-2—SBA *vs* Packets/s

***S* Packets/s**	***SBA***	**Estimated *SBA***
50	1.26	1.241
95	1.221	1.220
190	1.189	1.197
285	1.179	1.183
380	1.168	1.174
475	1.164	1.167
570	1.160	1.161
665	1.156	1.156
760	1.154	1.151
855	1.151	1.147
950	1.151	1.144
1900	1.139	1.121

The values for *SBA* as shown in Table K-2 are based upon a one second time period and hence are what should be used in the TSPEC for EDCA Admission Control. The value used in an HCCA TSPEC might be different.

In an HCCA TSPEC the *SBA* relates the overhead required in each scheduled period. A voice stream, for example, sends only one packet every 20 ms. Obviously an *SBA* of 1.26 is meaningless as it does not allow even one retry. To allow just one retry, the minimum *SBA* is 2.0. Similarly for a video example of 6 packets per schedule period, to allow at least one retry would require an *SBA* of (6+1)/6 = 1.167.

Hence, for an HCCA TSPEC:

Calculate packets per SI:

$$PPSI = \frac{R_m}{S_n \times 8 \times SI}$$

where

R_m is the mean data rate (b/s)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

S_n is the nominal MDSU size (octets)
SI is the service interval (seconds)

Then Minimum HCCA $SBA = \text{MAX}\left(SBA, \frac{PPSI + 1}{PPSI}\right)$.

Table K-3 shows the recommended SBA values for HCCA TSPECs for various video streams.

Table K-3—HCCA SBA for video streams

Video, Mb/s	Pkts per SI	Min HCCA SBA	SBA, (1 s)	HCCA SBA
1	1	2.000	1.221	2.000
2	3	1.333	1.189	1.333
3	4	1.250	1.179	1.250
4	6	1.167	1.168	1.168
5	7	1.143	1.164	1.164
6	9	1.111	1.160	1.160
7	10	1.100	1.156	1.156

20	30	1.033	1.139	1.139

In summary, the suggested value for SBA is derived as follows:

— Calculate packets/s , PPS

$$PPS = \frac{R_m}{S_n \times 8}$$

where
R_m is the mean data rate (b/s)
S_n is the nominal MDSU size (octets)
NOTE—Nominal MSDU = MDSU or A-MSDU

— Calculate SBA

$$SBA = -0.033 \ln(PPS) + 1.37$$

EDCA Admission Control TSPEC and Medium Time calculation uses SBA.

For HCCA TSPEC:

— Calculate packets per SI, PPSI

$$PPSI = \frac{R_m}{S_n \times 8 \times SI}$$

where

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

R_m is the mean data rate (b/s)
S_n is the nominal MDSU size (octets)
SI is the service interval (seconds)

— HCCA $SBA = \text{MAX}\left(SBA, \frac{PPSI+1}{PPSI}\right)$

HCCA Medium Time uses SBA in place of HCCA SBA, if different.

K.4.3 Minimum and Maximum Service Interval

K.4.3.1 Scheduled traffic

The HC uses the Maximum Service Interval for the calculation of the schedule.

The value of the Minimum Service Interval is an indication that the traffic is CBR or VBR.

For CBR traffic the minimum and maximum Service Intervals should be set to the same value. For example, most voice traffic requires a minimum and maximum service interval value of 20 ms.

In the case of VBR traffic, such as video, Minimum Service Interval should be set to 0 and the Maximum Service Interval set to the service interval required by the application, e.g., to correspond to the codec that is to be used For example, Maximum Service Interval is set to 16 ms for many real time video applications.

K.4.3.2 Use of Maximum Service Interval with Aggregation of Packets

Aggregation of MPDUs or MSDUs introduces delay to the packets, but the use of aggregated packets is to be encouraged because of the increased efficiency. In the case of scheduled traffic, the aggregation of packets is such that the number of MSDUs that are aggregated into a single packet (A-MSDU or A-MPDU) does not exceed the scheduling service interval. Consider the following example:

— Video packet = 1316 B (7 × 188 MPEG2-TS)
— Nominal MSDU Size = 1364 (octets)
— Mean Data Rate = 4 Mb/s
— Maximum Service Interval = 16 ms

$$\text{Nominal MSDUs per SI} = \left\lfloor \frac{4 \times 10^6}{1364 \times 8} \right\rfloor = 3$$

Hence, to comply with the 16 ms SI, the limit for aggregation is 3, (an A-MSDU of 3 MSDUs, or an A-MPDU consisting of 3 MSDUs).

In the case of EDCA Admission Control, where regular scheduling is not used, the value of the Maximum Service Interval is used to indicate the limit of aggregation of nominal MSDUs and the acceptable latency between packets. Using aggregation reduces the Medium Time and Used Time required.

For example, assuming a minimum PHY Rate of 39 Mb/s for the example used above, the accurate Medium Time returned by the AP would be 13 783 μs. If the AP assumed that A-MPDUs were to be used, then the accurate Medium Time would be 11 681 μs, a 15% reduction. Hence, an AP could ‘force’ a STA to use aggregation, or alternatively could assume aggregation when it is considering the total traffic as part of its admittance policy.

The Nominal MSDU Size is the size of the MSDU or A-MSDU belonging to the TS.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Consider another example:

— Video packet = 1316 B (7 × 188 MPEG2-TS)
— Nominal MSDU Size = 4137 (A-MSDU of 3 MSDUs)
— Mean Data Rate = 10 Mb/s
— Maximum Service Interval = 16 ms

$$\text{Nominal MSDUs per SI} = \left\lfloor \frac{10 \times 10^6}{4137 \times 8} \right\rfloor = 4$$

Hence, further aggregation is possible and an A-MPDU consisting of 4 A-MSDUs could be sent and still comply with the latency or SI requirement.

Note that the TSPEC is invalid if the Nominal MSDUs per Maximum Service Interval is less than 1.

K.4.4 Minimum, Mean, and Peak Data Rate

In an HCCA TSPEC, for CBR traffic the Minimum, Mean and Maximum Data Rate fields should contain the same value but it is allowable to just specify the Mean Data Rate noting that the Minimum and Maximum Service Intervals are the same.

In an EDCA TSPEC, for CBR traffic the Minimum, Mean and Maximum Data Rate fields should contain the same value but it is allowable to just specify the Mean Data Rate.

For VBR traffic it is desirable to populate the Minimum, Mean and Peak data rate fields.

If a TSPEC has the Minimum Data Rate (R_{min}) and Peak Data Rate (R_{max}) fields populated, then the standard deviation of that stream, σ, can be estimated as follows:

$$\sigma = 0.25(R_{max} - R_{min})$$

If a TSPEC has the Mean Data Rate (R_{mean}) and Peak Data Rate fields populated, then the standard deviation of that stream, σ, can be estimated as follows:

$$\sigma = 0.5(R_{max} - R_{mean})$$

If there are *n* streams, the values of the mean μ and standard deviation σ, of the total stream traffic should be calculated using:

$$\mu = \sum \mu_n$$

$$\sigma_{tot} = \sqrt{\sum \sigma_n^2}$$

This is of particular use to EDCA admission control policy. When summing streams for EDCA Admission Control, the EDCA Overhead Factor needs to be taken into account; see T.2.7.

Annex L

(informative)

Examples and sample code for encoding a TIM Partial Virtual Bitmap

L.1 Introduction

The purpose of this annex is to show an examples of encoding a Partial Virtual Bitmap field of the TIM element, as described in 9.4.2.5. Sample C code is provided in L.3.

L.2 Examples

The following examples help clarify the use of TIM values, both with and without the multiple BSSID capability for non-S1G STAs, with multiple BSSID Capability for S1G STAs as well as the use of the encoding modes of Block Bitmap, Single AID, OLB, ADE, Inverse Bitmap + Block Bitmap, Inverse Bitmap + Single AID, Inverse Bitmap + OLB and Inverse Bitmap + ADE of TIM element for S1G STAs.

The first example is one in which there are no group addressed MSDUs buffered in the AP but there is traffic for two STAs queued in the AP. STAs with AID 2 and AID 7 have data buffered in the AP. Figure L-1 shows the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example.

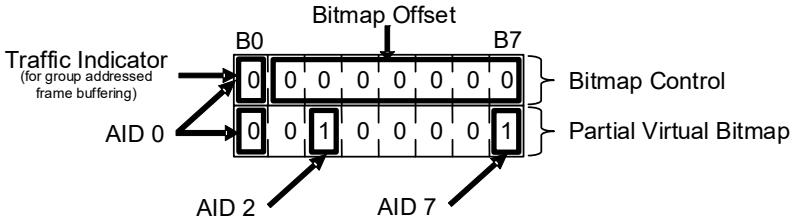

Figure L-1—Partial Virtual Bitmap example #1

The next example is one in which group addressed MSDUs are buffered in the AP as well as traffic for STAs. The DTIM Count field in the TIM element equals 0. STAs with AID 2, AID 7, AID 22 and AID 24 have data buffered in the AP. Figure L-2 shows the values of the Bitmap Control and Partial Virtual Bitmap fields.

Another example is one in which group addressed MSDUs are buffered in the AP as well as traffic for STAs. The DTIM Count field in the TIM element equals 0. Only the node with AID 24 has data buffered in the AP. In this example, the Bitmap Offset is used to start the Partial Virtual Bitmap at the third octet. Figure L-3 shows the values of the Bitmap Control and Partial Virtual Bitmap fields.

Figure L-2—Partial Virtual Bitmap example #2

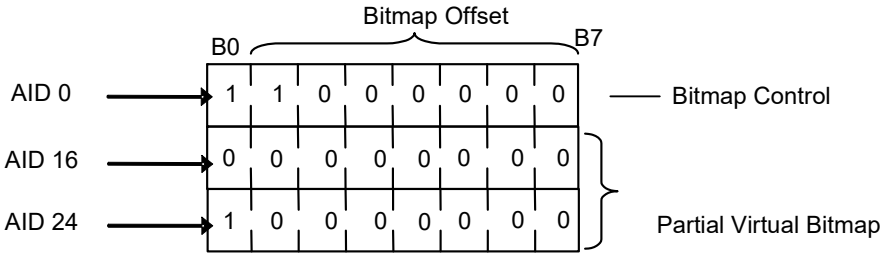

Figure L-3—Partial Virtual Bitmap example #3

The three examples listed above describe the construction of the Partial Virtual Bitmap when multiple BSSID operation is not supported. The following three examples demonstrate how to construct the Partial Virtual Bitmap, when multiple BSSID operation is supported.

The first example showing multiple BSSID operation is one in which there are eight BSSIDs and the lowest possible AID that can be assigned to any STA in this example is 8. There are no group addressed frames buffered in the AP for any of the eight BSSIDs. However, STAs with AID 9 and AID 11 have an individually addressed frames buffered in the AP. Figure L-4 shows the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example when either Method A or Method B is used. It is noted that Method B reduces to Method A in this example.

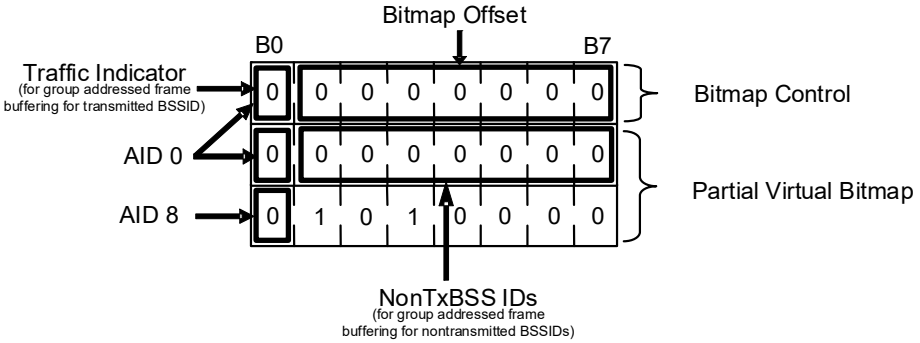

Figure L-4—Partial Virtual Bitmap example #4, Method A and Method B

In the next example, there are eight BSSIDs and the lowest possible AID that can be assigned to any STA in this example is 8. There are group addressed frames buffered at the AP for the transmitted BSSID, and the DTIM Count field in the TIM element of the transmitted BSSID is 0. The nontransmitted BSSID with BSSID Index 3 also has the DTIM Count field set to 0 and has buffered group addressed frames. All other nontransmitted BSSIDs have no buffered group addressed frames. In addition, STAs with AID 12, AID 17, AID 22 and AID 24 have data buffered at the AP. Figure L-5 shows the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example when either Method A or Method B is used. It is noted that Method B reduces to Method A in this example.

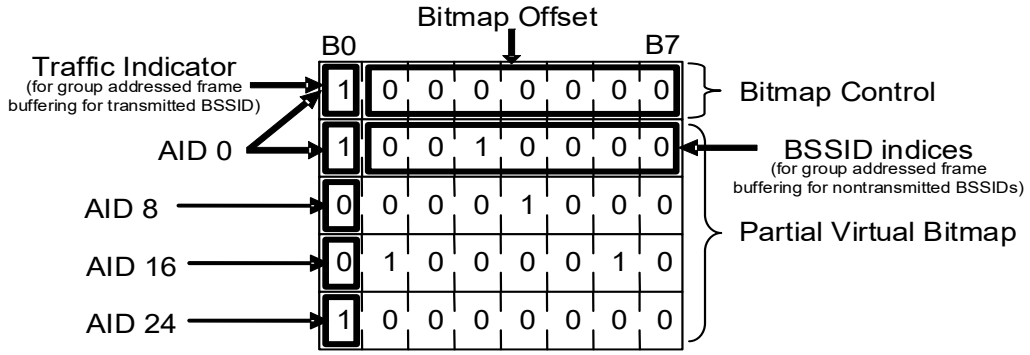

Figure L-5—Partial Virtual Bitmap example #5, Method A or Method B

In the third example, there are sixteen BSSIDs and the lowest possible AID that can be assigned to any STA is 16 (*n*=4, see 9.4.2.5. There are no group addressed frames buffered at the AP for the transmitted BSSID, and the DTIM Count field in the TIM element of the transmitted BSSID is 0. The nontransmitted BSSID Index 3 also has the DTIM Count field set to 0 and has group addressed frames buffered at the AP. All other nontransmitted BSSIDs have no buffered group addressed frames. In addition, the STA with AID 39 has individually addressed frames buffered at the AP. Figure L-6 and Figure L-7 show the values of the Bitmap Control and Partial Virtual Bitmap fields that would be part of the TIM element for this example when Method A (*N2*=4, see 9.4.2.5) and Method B (*N0*=2, *N1*=4, *N2*=4, see 9.4.2.5) are used, respectively.

Figure L-7—Partial Virtual Bitmap example #6, Method B

The examples listed above describe the construction of the TIM Virtual Bitmap for non-S1G STAs. The following eight examples demonstrate how to construct the TIM element for S1G STAs.

The first example is one in which group addressed MSDUs are buffered in the AP as well as traffic for S1G STAs. The TIM element uses the encoding mode of Block Bitmap. The DTIM Count field in the TIM element equals 0. The Traffic Indicator field is 1, the Page Slice Number field in the TIM element is 0 and the Page Index field is 0. The STAs with AID 1, AID 6, AID 21 and AID 23 have data buffered in the AP. Figure L-8 shows the values of the Bitmap Control and Partial Virtual Bitmap fields. The Partial Virtual Bitmap field consists of only one encoded block in which the Block Control field is 0 and the Block Offset field is 0. The Encoded Information Block field in the Partial Virtual Bitmap field consists of Block Bitmap field with the value of 3 and two Subblock fields with the value of 66 and 160, respectively.

The second example is one in which group addressed MSDUs are buffered in the AP as well as traffic for S1G STAs. The TIM element uses Single AID mode. The DTIM Count field in the TIM element equals 0. The Traffic Indicator field is 1, the Page Slice Number field in the TIM element is 0 and the Page Index field is 0. Only the STA with AID 31 has data buffered in the AP. Figure L-9 shows the values of the Bitmap Control and Partial Virtual Bitmap fields. The Partial Virtual Bitmap field consists of only one encoded block in which the Block Control field is 1 and the Block Offset field is 0. The Encoded Information Block field in the Partial Virtual Bitmap field consists of one Single AID field with the value of 31.

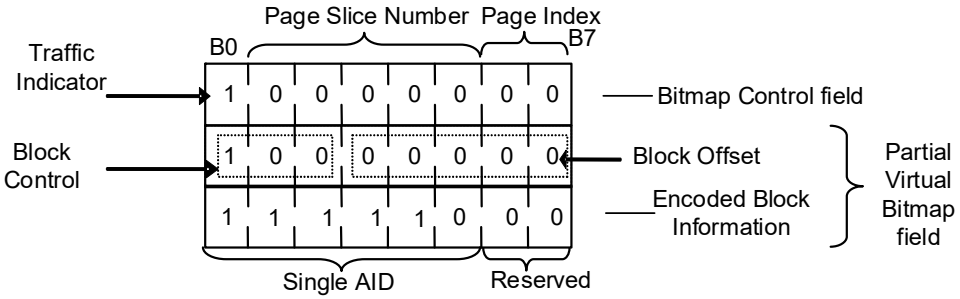

Figure L-9—Partial Virtual Bitmap example #8 for S1G STAs, Single AID mode

The third example is one in which group addressed MSDUs are buffered in the AP as well as traffic for S1G STAs. The TIM element uses OLB mode. The DTIM Count field in the TIM element equals 0. The Traffic Indicator field is 1, the Page Slice Number field in the TIM element is 0 and the Page Index field is 0. The STAs with AID 1, AID 6, AID 13, AID 15, AID 17, AID 22, AID 29, AID 31, AID 33, AID 38, AID 45, AID 47, AID 49, AID 54, AID 61, AID 63, AID 65, and AID 70 have data buffered in the AP. Figure L-10 shows the values of the Bitmap Control and Partial Virtual Bitmap fields. The Partial Virtual Bitmap field consists of only one encoded block in which the Block Control field is 2 and the Block Offset field is 0. The Encoded Information Block field in the Partial Virtual Bitmap field consists of one Length field with the value of 9 and nine Subblock fields with the value of 66, 160, 66, 160, 66, 160, 66, 160, and 66, respectively.

The fourth example is one in which group addressed MSDUs are buffered in the AP as well as traffic for S1G STAs. The TIM element uses ADE mode. The DTIM Count field in the TIM element equals 0. The Traffic Indicator field is 1, the Page Slice Number field in the TIM element is 0 and the Page Index field is 0. The STAs with AID 1, AID 6, AID 21 and AID 23 have data buffered in the AP. Figure L-11 shows the values of the Bitmap Control and Partial Virtual Bitmap fields. The Partial Virtual Bitmap field consists of only one encoded block in which the Block Control field value is 3 and the Block Offset field value is 0. The Encoded Information Block field in the Partial Virtual Bitmap field consists of only one ADE Block in which the EWL field is 4 and the Length field is 2. Four differential AID values (ΔAID), i.e., 1, 5, 15, and 2 are encoded in the Encoded Information Block that has zero padding bits.

The fifth example is one in which group addressed MSDUs are buffered in the AP as well as traffic for S1G STAs. The TIM element uses the encoding mode of Inverse Bitmap + Block Bitmap. The DTIM Count field in the TIM element equals 0. The Traffic Indicator field is 1, the Page Slice Number field in the TIM element is 0 and the Page Index field is 0. All the STAs with the AID value smaller than 64 except AID 1, AID 6, AID 21 and AID 23 have data buffered in the AP. Figure L-12 shows the values of the Bitmap Control and Partial Virtual Bitmap fields. The Partial Virtual Bitmap field consists of only one Encoded Block in which the Block Control field is 4 and the Block Offset field is 0. The Encoded Information Block field in the Partial Virtual Bitmap field consists of Block Bitmap field with the value of 5 and two Subblock fields with the value of 66 and 160, respectively.

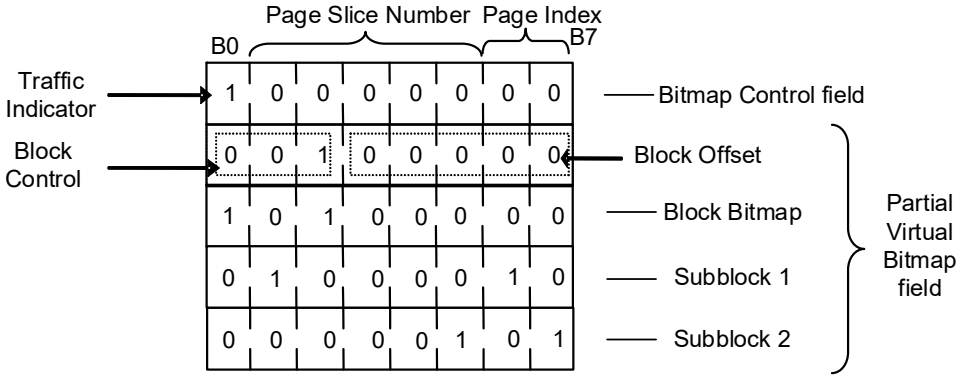

Figure L-12—Partial Virtual Bitmap example #10 for S1G STAs, Inverse Bitmap + Block Bitmap mode

The sixth example is one in which group addressed MSDUs are buffered in the AP as well as traffic for S1G STAs. The TIM element uses the encoding mode of Inverse Bitmap + Single AID. The DTIM Count field in the TIM element equals 0. The Traffic Indicator field is 1, the Page Slice Number field in the TIM element is 0 and the Page Index field is 0. All the STAs with the AID value smaller than 64 except AID 31 have data buffered in the AP. Figure L-13 shows the values of the Bitmap Control and Partial Virtual Bitmap fields. The Partial Virtual Bitmap field consists of only one Encoded Block in which the Block Control field is 5 and the Block Offset field is 0. The Encoded Information Block field in the Partial Virtual Bitmap field consists of one Single AID field with the value of 31.

The seventh example is one in which group addressed MSDUs are buffered in the AP as well as traffic for S1G STAs. The TIM element uses the encoding mode of Inverse Bitmap + OLB. The DTIM Count field in the TIM element equals 0. The Traffic Indicator field is 1, the Page Slice Number field in the TIM element is 0 and the Page Index field is 0. All the STAs with the AID value smaller than 128 except AID 1, AID 6, AID 13, AID 15, AID 17, AID 22, AID 29, AID 31, AID 33, AID 38, AID 45, AID 47, AID 49, AID 54, AID 61, AID 63, AID 65, and AID 70 have data buffered in the AP. Figure L-14 shows the values of the Bitmap Control and Partial Virtual Bitmap fields. The Partial Virtual Bitmap field consists of only one Encoded Block in which the Block Control field is 6 and the Block Offset field is 0. The Encoded Information Block field in the Partial Virtual Bitmap field consists of one Length field with the value of 9 and nine Subblock fields with the value of 66, 160, 66, 160, 66, 160, 66, 160, and 66, respectively.

The eighth example is one in which group addressed MSDUs are buffered in the AP as well as traffic for S1G STAs. The TIM element uses the encoding mode of Inverse Bitmap + ADE. The DTIM Count field in the TIM element equals 0. The Traffic Indicator field is 1, the Page Slice Number field in the TIM element is 0 and the Page Index field is 0. All the STAs with the AID value smaller than 64 except AID 1, AID 6, AID 21 and AID 23 have data buffered in the AP. Figure L-15 shows the values of the Bitmap Control and Partial Virtual Bitmap fields. The Partial Virtual Bitmap field consists of only one Encoded Block in which the Block Control field value is 7 and the Block Offset field value is 0. The Encoded Information Block field in the Partial Virtual Bitmap field consists of only one ADE Block in which the EWL field is 4 and the Length field is 2. Four differential AID values (ΔAID), i.e., 1, 5, 15, and 2 are encoded in the Encoded Information Block that has zero padding bits.

Annex M

(informative)

EPD and LPD headers and the integration function

M.1 Introduction

The purposes of this informative annex are to (1) guide the implementer of a non-GLK WLAN system that includes a portal that integrates the WLAN systems with a wired LAN, (2) clarify EPD and LPD headers including the case of A-MSDU subframes, and (3) clarify where and how EPD to LPD and LPD to EPD conversions are required.

As specified in IEEE Std 802, EPD encoding always starts with a Length/Type field that is either a 2-octet length or a 2-octet EtherType while LPD encoding always starts with an LSAP octet. There is no indication in a Data frame as to whether EPD or LPD MSDU encoding is in use. A receiving STA uses the rules in 5.1.4 to determine the encoding of MSDUs it receives.

M.2 Integration function header conversions

Table M-1 illustrates EPD and LPD protocol header encodings. The encoding used within the DS is unspecified. If the DS has a portal, that portal provides the integration function. The integration function converts between the encoding used within the DS and that used in the non-IEEE-802.11 network with which the portal is connecting the DS. If the DS uses LPD and the portal connects to a network that uses EPD, for example IEEE Std 802.3-2022, the integration function converts MSDUs exiting the DS from LPD to EPD format and those entering the DS from EPD to LPD.

Conversion between LPD and EPD might also be required at any GLK STA unless the GLK STA joins only BSSs limited to EPD STAs. If the GLK STA might receive or transmit Data frames containing LPD MSDUs, it converts them to or from the EPD MSDUs required by the Internal Sublayer Service SAPs provided by GLK STAs.

Conversion between LPD and EPD is discussed in 5.1.4 and IEEE Std 802.1AC-2016.

M.3 A-MSDU subframes

The formats of A-MSDU subframes are shown in 9.3.2.2, specifically in Figure 9-122, Figure 9-123, and Figure 9-124. These formats apply as shown regardless of whether the MSDU is EPD or LPD encoded.

When the MSDU is EPD encoded, it always starts with a 2-octet Length/Type field as shown in Table M-1. Thus, in the case where that field is a length (indicated by its value considered as an unsigned field being less than 0x05DC) and the MSDU appears in an A-MSDU subframe, there are two sequential length fields or, in the mesh Data frame case, two length fields separated only by the Mesh Control field. Figure M-1, Figure M-2, and Figure M-3 show Basic A-MSDU subframes containing an EPD encoded BPDU, an EPD encoded VLAN tagged IPv4 packet, and an EPD encoded VLAN tagged IS-IS PDU respectively. In those figures, the arrowed line from each Length field goes to a curly bracket covering the data whose Length is in that length field.

When parsing an MSDU, if the default LPD encoding is being used, the MSDU starts with an LSAP; if EPD encoding is being used, the MSDU starts with a Length/Type field. Subclause 5.1.4 specifies which encoding is used.

M.4 Integration service versus bridging

There are a number of differences between the IEEE 802.11 integration service and the service provided by an IEEE 802.1 bridge. In the IEEE 802.11 non-GLK architecture a portal provides the minimum connectivity between an IEEE 802.11 WLAN and a non-IEEE-802.11 LAN. Requiring an IEEE 802.1Q bridge in order to be compliant with IEEE Std 802.11 would unnecessarily render some implementations noncompliant.

The most important distinction is that a portal has only one “port” (in the sense of IEEE Std 802.1Q, for example) through which it accesses the DS. This renders it unnecessary to update bridging tables inside a portal each time a STA changes its association status. In other words, the details of distributing MSDUs inside the non-GLK IEEE 802.11 WLAN need not be exposed to the portal.

Another difference is that the DS is not an IEEE 802 LAN (although it carries IEEE 802 LLC SDUs). Requiring that the DS implements all behaviors of an IEEE 802 LAN places an undue burden on the architecture.

Finally, it is an explicit intent of this standard to permit transparent integration of an IEEE 802.11 WLAN into another non-IEEE-802.11 LAN, including passing bridge PDUs through a portal. While an implementer might wish to attach an IEEE 802.1Q bridge to the portal (note that the non-IEEE-802.11 LAN interface on the bridge need not be any particular type of LAN), it is not an architectural requirement of this standard to do so.

Annex N

(informative)

AP functional description

N.1 Introduction

This informative annex seeks to clarify the AP functional description; however, it does not provide information or clarification for GLK APs. At times there is some confusion surrounding the term *AP* and the relation of that term to the AP functions and common implementations of AP devices. The core IEEE 802.11 conceptual definitions that surround the AP (refer to Clause 4) are abstract (and can sometimes cause confusion), but Clause 4 definitions are crafted to be flexible and hence serve to allow the adaptation and extension of this standard in a wide variety of ways.

In this annex a wireless local area network (WLAN) system is a system that includes the distribution system (DS), access point (AP), and portal entities. It is also the logical location of distribution and integration service functions of an extended service set (ESS). A WLAN system contains an optional portal and one or more APs in addition to the DS.

N.2 Terminology

An enhanced description of these access entities begins with clarification of several terms.

This standard defines an entity called a *STA*. STAs can operate in different modes. The possible operational modes of a STA are:

a) Infrastructure mobile STAs
b) Independent mobile STAs
c) Access control mode STAs
d) Mesh STAs

The mobile STAs are the STA entities that are ordinarily moving around, but might also be in a fixed location. The mobile adjective prefix often helps in visualizing the type of STA under discussion.

Infrastructure mobile STAs operate in an infrastructure BSS, i.e., they are the users of an AP. Devices that incorporate an infrastructure mobile STA are referred to in this annex by the term mobile unit. A mobile unit device might consist of just a mobile STA implementation, but also likely includes an SME and a client. The exact configuration of the mobile unit it is not relevant to the descriptions in this annex.

Independent mobile STAs operate in an IBSS. Independent mobile STAs form autonomous networks that do not require an AP.

A STA can also form an integral part of an AP. To do so, the STA operates in access control mode. This type of STA is called an *access control mode STA* (ACM_STA).

The primary function of an AP is to provide the mobile units with access to the DS, as shown in the Unified Modeling Language (UML) use case diagram in Figure N-1. Complete UML specifications can be found in Rumbaugh et al. [B67]. The UML diagram shows a system boundary box containing a single use case (ellipse). Entities that are outside the system boundary box are shown as stick people. These external entities

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

represent the actors (formal term), or users, of the system. Since the actors are outside the system boundary, their internal behavior is not described (i.e., it is out of scope for the current view). Instead, references to the external entities are limited to descriptions of their interactions with, and expectations of, the system, which is accomplished by describing the use cases and scenarios (i.e., functions) of the system and later (in Figure N-4) a decomposition of the entities (objects and behaviors) within the system that provide that functionality. The use case diagram employs connecting lines to indicate relationships between the various artifacts present in the diagram. Relationship lines lacking arrows on both ends indicate that there is a bidirectional relationship between the artifacts.

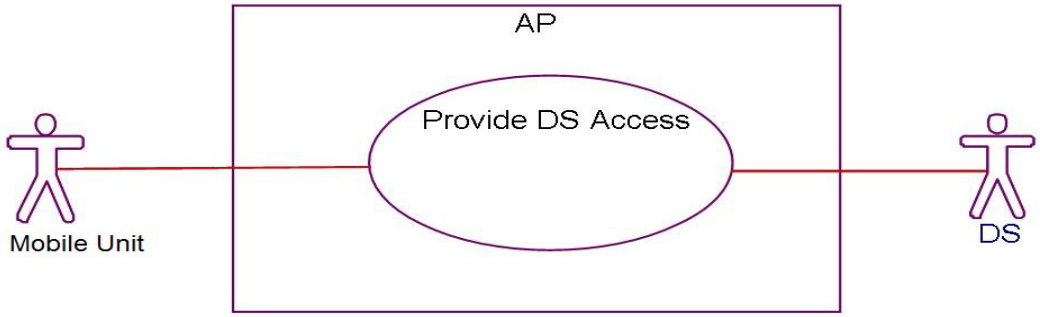

Figure N-1—Very high level UML use case diagram for the AP

The DS enables communication between mobile units and the construction of collections of APs. To enable communication between mobile units and a non-IEEE-802.11 LAN entity requires the presence of a (logical) portal from the DS to the non-IEEE-802.11 LAN.

Often the functions of an AP (which includes an ACM_STA), a DS, and a portal, are combined into a single device, referred to in this annex as an *access unit* (AU). While reference to that basic implementation is commonplace, it is helpful to discuss the abstract case: a WLAN system. The WLAN system includes the DS, an optional portal, APs, and the AP's STAs. It is also the logical location of distribution and integration service functions of an ESS. An infrastructure WLAN system contains one or more APs and zero or one portals in addition to the DS.

The primary function of a WLAN system is to provide the mobile units with access to the non-IEEE-802.11 LAN, as shown in Figure N-2. A secondary function is to provide the mobile units with access to each other.

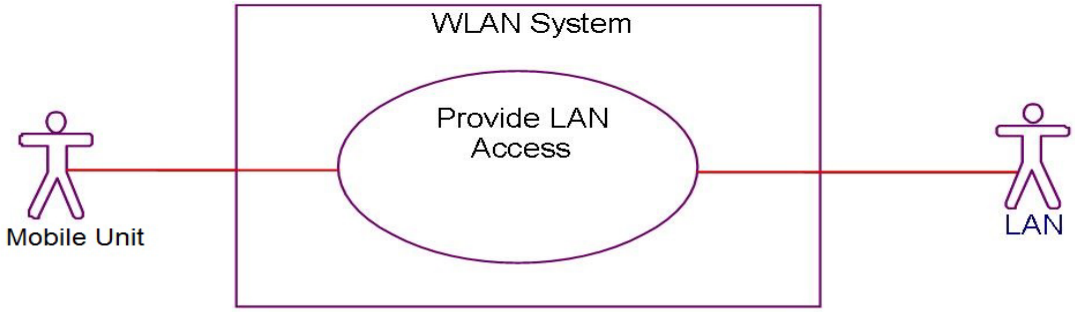

Figure N-2—Very high level UML use case diagram for the WLAN system

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The primary functions of the WLAN system can be further characterized as follows:

a) Provide non-IEEE-802.11 LAN access.
   1) Includes mobile unit validation.
   2) Includes moving data between the mobile units and the non-IEEE-802.11 LAN.
      i) Uses a special data movement function called *filtering data*.

b) Configure the system.

Those high-level use cases of the WLAN system are shown in the UML use case diagram in Figure N-3. The UML diagram shows multiple use cases with two types of relationships between those use cases: include and generalization. The include relationship "includes" functionality in one use case that is described by another use case. The "provide LAN Access" use case includes the functionality of the "Validate mobile unit" use case. The generalization relationship indicates that one use case is a more general form of another use case. The relationship line with a hollow triangle at the end indicates that the "Move Data" use case is a more generalized form of the "Filter Data" use case. Or, equivalently, "Filter Data" is a more specialized form of "Move Data." The constraint artifact (in the lower left corner of the diagram) requires the WLAN system and the mobile units to be set to the same SSID.

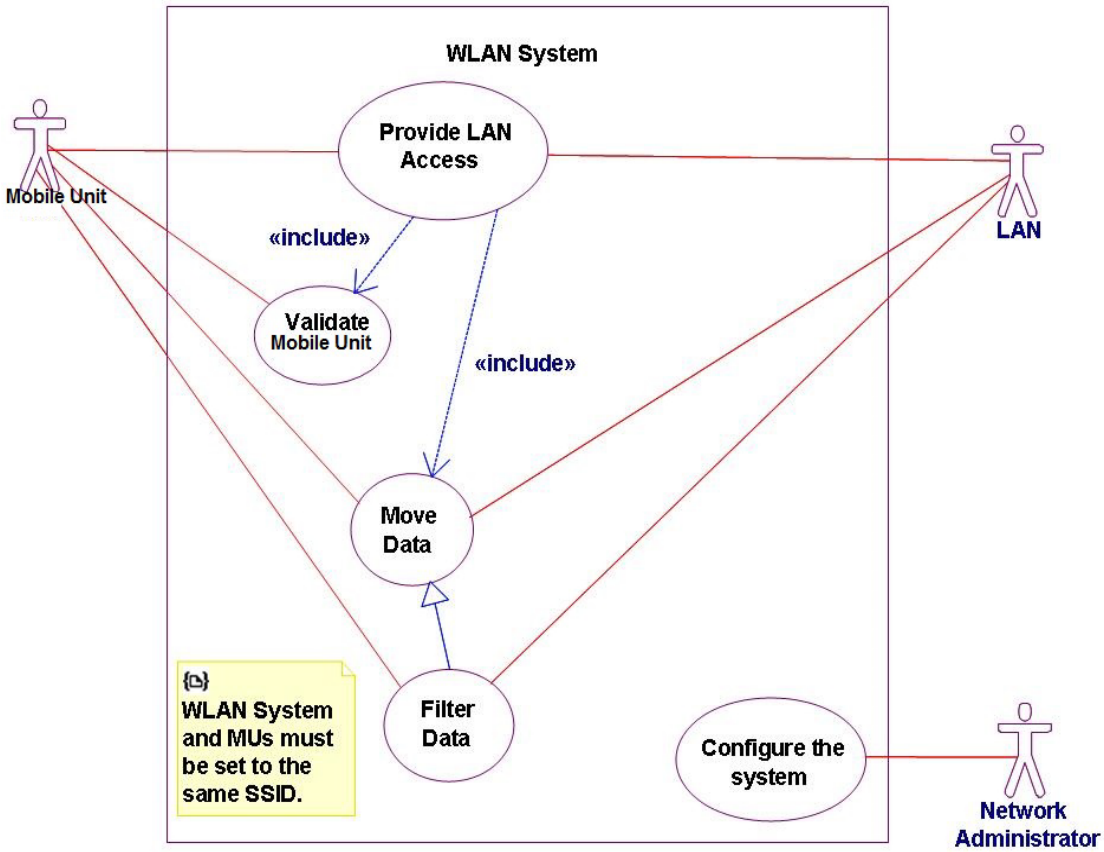

Figure N-3—High-level UML use case diagram for the WLAN system

The primary functions of the WLAN system, depicted in the UML object model diagram in Figure N-4, are provided by the AP, and DS entities, the latter via the DSSs. The portal is merely a conceptual link from the DS to the non-IEEE-802.11 LAN. The UML object model diagram shows a package containing a set of object classes. References to the actors (external entities) are limited to descriptions of their interactions

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

with, and expectations of, the object classes, which is accomplished by describing the attributes and behaviors of the class entities. The object model diagram uses connecting lines to indicate interfaces (called *associations* in UML terminology) between the various artifacts present in the diagram. UML association lines lacking arrows on both ends indicate that there is a bidirectional interface between the artifacts. The UML association lines are annotated with multiplicity counts to indicate the how many entities might fill the position at that end of the association.

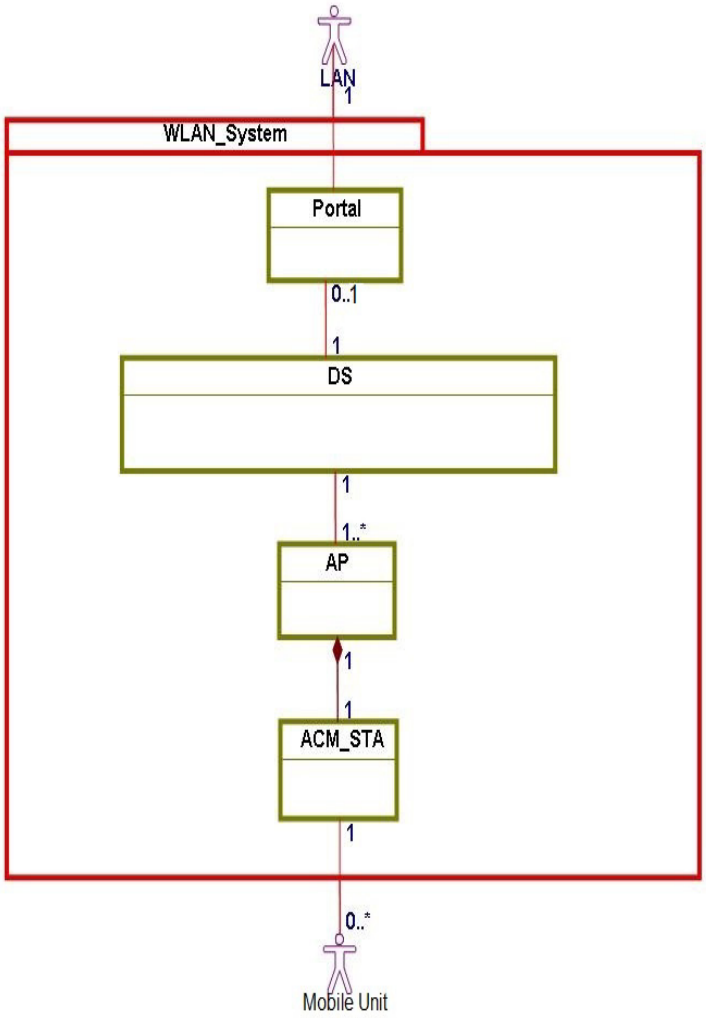

Figure N-4—High-level UML entity diagram for the WLAN system

Figure N-4 also shows the relationships between the WLAN system entities. There exists a bidirectional association between zero or more [0..*] mobile units and a single (given) ACM_STA. The solid diamond terminated line indicates that there is a composition relationship between the ACM_STA and the AP, i.e., the AP is composed of (or always has an) ACM_STA. Hence there is a one-to-one mapping between APs and ACM_STAs. This composition and one-to-one relationship can also be drawn as shown in Figure N-5. These two forms are equivalent. There are one or more [1..*] APs connected to a single DS. The DS in turn connects to zero or one [0..1] portals. The portal connects to a single non-IEEE-802.11 LAN.

Figure N-5—AP UML composition diagram (alternate syntax)

N.3 Primary ACM_STA functions

The primary functions of an ACM_STA are as follows:

a) Instantiate the infrastructure BSS.
b) Move data between the mobile units and the AP.

Instantiating the infrastructure BSS consists of advertising the BSS and defining timing for the entire BSS (i.e., infrastructure mode TSF). Advertising the BSS includes creating an infrastructure mode Beacon frame, transmitting that Beacon frame, and replying to mobile unit probe requests with corresponding probe response transmissions. Beacon frames and probe responses provide a way for the mobile units to find, join with the ACM_STA, and (subsequently) associate with the AP. This includes, for example, the AP providing channel, regulatory, and country information to the mobile units.

Moving data between the mobile units and the AP consists of translating between MSDUs and MPDUs, buffering data, and transmitting/receiving MPDUs via an IEEE 802.11 PHY.

N.4 Primary AP functions

The primary functions of an AP are as follows:

a) Provide DS access for the mobile units.
    1) Includes mobile unit validation and extends (in some cases) to notifying the DS.
    2) Includes moving data between the mobile units and the DS.
        i) Uses a special data movement function called *data filtering*.
b) Configure the AP (both the AP itself and the included ACM_STA).

Those high-level use cases of the AP are shown in the UML use case diagram in Figure N-6. The UML extend relationship “extends” a use case with optional functions provided by another use case that are applied only in some scenarios. In Figure N-6, the “Notify the DS” use case extends the “Validate mobile unit” use case in some scenarios.

Figure N-6—High-level UML use case diagram for the AP

The AP provides DS access for the mobile units, including validating the mobile units (e.g., via STA and/or client authentication) and providing access and admission control (e.g., via the association process). An AP is literally a point of access to the DS (and, by extension, to the non-IEEE-802.11 LAN beyond). Upon validating a mobile unit, the AP updates the DS mapping of the mobile unit to the AP. DS mapping updates can, for example, be based on (re)association requests (received from the ACM_STA) or aging of inactive links (based on session timers). An AP might also receive access control updates directly from other APs, via a protocol outside the scope of this standard, in the form of inter-AP notifications of mobile unit association events and transitions. In this way, mobile unit validation and subsequent changes in mobile unit access control lead to adjustments in how data are allowed to move through the AP (i.e., between the mobile units and the DS).

Providing DS access for the mobile units also includes moving data between the mobile units and the DS, which is accomplished by moving MSDUs between the ACM_STA and the DS (bidirectionally).

The moving data function includes “filtering data.” The filtering data function controls which MSDUs (if any) are moved between the DS and the mobile units. For example, filtering of data to and from a particular mobile unit is adjusted based on the various stages of validation of that mobile unit.

The AP also provides a function for configuration. Configuring the AP includes configuring the AP itself as well as the included ACM_STA. For example, configuration might include setting the local values of the SSID, PHY channel, beacon interval, and so on.

N.5 Primary DS functions

The primary functions of the DS (i.e., the DSSs) are as follows:

a) Map mobile unit to AP (for DS-to-mobile unit traffic delivery).
b) Move data.

The DS's mobile unit-to-AP map determines which AP is to be used for a given mobile unit's data delivery. This function includes mapping update adjustments, which are based on notification from the APs, of changes in mobile unit access control.

Moving data consists of moving MSDUs among the APs (including returning MSDUs to the source AP for mobile unit-to-mobile unit communications) and between the APs and the portal.

N.6 Primary portal function

The primary function of a portal is as follows:

a) Move data with a special data movement function called *data transformation*.

Moving data consists of moving MSDUs between the DS and the external non-IEEE-802.11 LAN. Moving data through the portal transforms the MSDUs using the integration function. The integration function translates external non-IEEE-802.11-LAN MSDUs to and from IEEE 802.11 MSDUs using, for example, the procedures defined in Annex M.

Annex O

(informative)

Additional HT, VHT, and S1G information

O.1 HT, VHT, and S1G waveform generator tool

As an informative extension to this standard, waveform generator tools have been written to model the PHY transmission process described in Clause 17, Clause 18, Clause 19, Clause 21, and Clause 23.

The waveform generator can be downloaded from the public IEEE 802.11 document website. The waveform generator code that includes Clause 17, Clause 18, and Clause 19 is contained in document 11-06/1715, and the waveform generator description is contained in document 11-06/1714 (HT code). A description of the waveform generator that includes Clause 17, Clause 19, and Clause 21 and the waveform generator code itself is contained in document 11-11/0517 (VHT code). A description of the waveform generator that includes Clause 23 and the waveform generator code itself is contained in document 11-14/0631 (S1G code).

The purpose of these tools is to promote common understanding of complex PHY algorithms, facilitate device interoperability by providing reference test vectors, and assist researchers in industry and academia to develop next generation wireless solutions.

The code is written in the MATLAB computing language and can be configured to generate test vectors for most PHY configurations, defined by this standard. Instructions on how to configure and run the tools are specified in the referenced documents.

A command line interface and graphic user interface (GUI) exist to configure the HT code tool. For consistency with this standard, the configuration interface is made very similar to the TXVECTOR parameters defined in 19.2.2.

A command line interface is used to configure the VHT code tool. For consistency with this standard, the configuration interface is made very similar to the TXVECTOR parameters defined in 21.2.2.

A GUI exists to configure the S1G code tool.

The HT and VHT waveform generator tool produces test vectors for all transmitter blocks, defined in Figure 19-2 and Figure 19-3, generating reference samples in both frequency and time domains. Outputs of the tool are time domain samples for all transmitting chains.#

The S1G waveform generator tool produces test vectors for transmitter blocks that support 1 MHz and 2 MHz channel widths, defined in 23.3.3 (Transmitter block diagram), generating reference samples in both frequency and time domains. Outputs of the tool are time domain samples for 1 and 2 spatial streams.

NOTE—In the case of a nonaggregated packet the S1G waveform generator tool does not correctly set the signal field length subfield to indicate the packet duration in number of octets in the PSDU.

O.2 A-MPDU deaggregation

This subclause contains a description of the deaggregation process. Other implementations are also possible.

The receiver checks the MPDU delimiter for validity based on the CRC. It can also check that the length indicated is within the value of the LENGTH parameter indicated in RXVECTOR.

If the MPDU delimiter is valid, the MPDU is extracted from the A-MPDU. The next MPDU delimiter is expected at the first multiple of 4 octets immediately after the current MPDU. This process is continued until the end of the PPDU is reached.

If the MPDU delimiter is not valid, the deaggregation process skips forward 4 octets and checks to see whether the new location contains a valid MPDU delimiter. It continues searching until either a valid delimiter is found or the end of the PSDU is reached based on the value of the LENGTH parameter indicated in the RXVECTOR.[64]

An A-MPDU parsing (deaggregation) algorithm is expressed (as a C programming language snippet) in Figure O-1.

```
void Parse_A_MPDU (int length)
{
  int offset = 0; /* Octet offset from start of PSDU */
  while (offset+4 < length)
  {
    if (valid_MPDU_delimiter(offset) &&
        get_MPDU_length(offset) <= (length -(offset+4)))
    { /* Valid delimiter */

      /* Receive the MPDU */
      Receive_MPDU(offset+4, get_MPDU_length(offset));

      /* advance by MPDU length rounded up to a multiple of 4 */
      offset += 4 + 4*((get_MPDU_length(offset)+3)/4);
    }
    else /* Invalid delimiter */
    {
      /* Advance 4 octets and try again */
      offset += 4;
    }
  }
}
```

NOTE 1—This algorithm is not optimized for efficiency.
NOTE 2—The delimiter signature can be used to reduce the amount of computation required while scanning for a valid delimiter. In this case, the receiver tests each possible delimiter for a matching Delimiter Signature field. Only when a match is discovered does it then check the CRC.

Figure O-1—A-MPDU parsing

[64] This procedure occasionally wrongly interprets a random bit-pattern as a valid delimiter. When this happens, the MAC attempts to interpret a random MPDU. The MAC discards it with a high probability based on a check of the FCS field.

O.3 Example of RD frame exchanges

Figure O-2 shows an example of the operation of the RD rules, defined in 10.29.

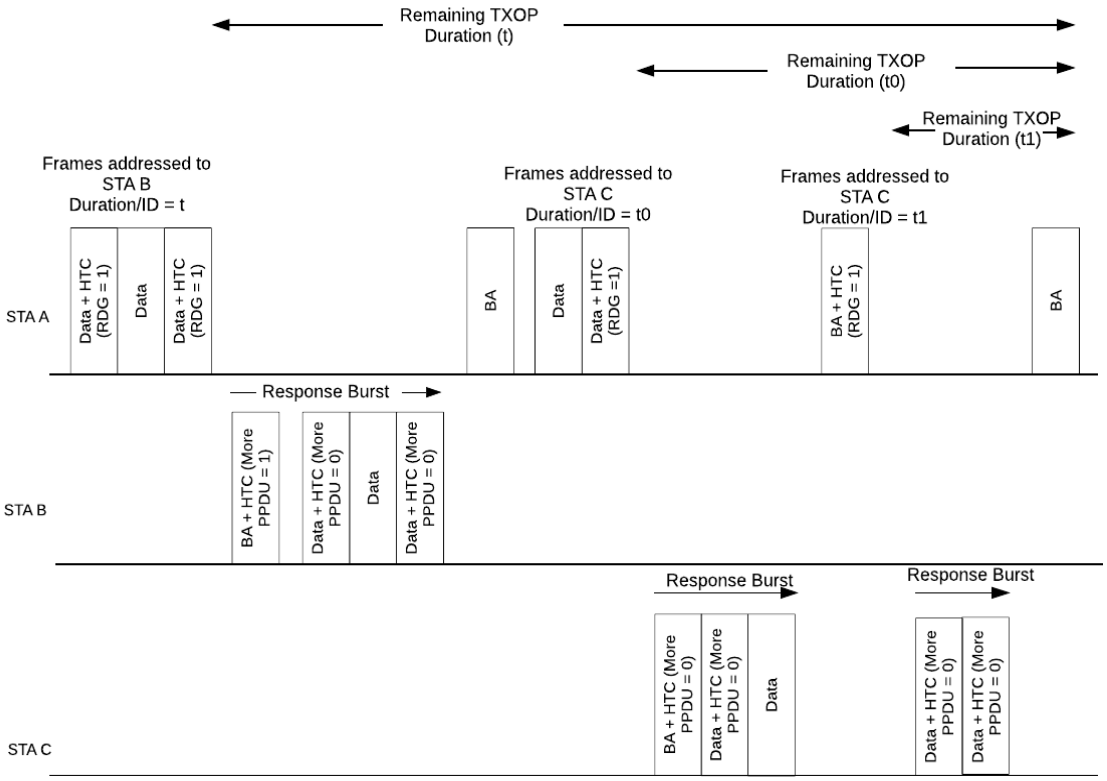

Figure O-2—Example of RD frame exchanges showing response burst

The following is a summary of Figure O-2:

a) STA A (acting as RD initiator) transmits a PPDU containing MPDUs addressed to STA B (acting as RD responder). The ack policy of the QoS Data frames in this PPDU is Implicit BAR. One or more MPDUs within this PPDU include an HT Control field with the RDG/More PPDU subfield set to 1, indicating an RDG. The Duration/ID field of MPDUs within the PPDU contains the remaining duration of the TXOP, t μs.

b) STA B (the RD responder) responds with the transmission of a +HTC BlockAck frame in which the RDG/More PPDU subfield is set to 1, indicating that another PPDU will follow a SIFS or RIFS after the end of the PPDU containing the BlockAck frame.

c) STA B transmits a PPDU (the second PPDU of an RD response burst) to STA A, with Implicit BAR ack policy for its QoS Data frames and containing one or more +HTC MPDUs in which the RDG/More PPDU subfield is set to 0, indicating that this is the last PPDU in the response burst.

d) STA A (the RD initiator) regains control of the TXOP and transmits a BlockAck frame addressed to STA B to acknowledge the MPDUs transmitted by STA B in the RD response burst.

e) STA A (the RD initiator) transmits a PPDU containing MPDUs addressed to STA C (acting as RD responder). The ack policy of the QoS Data frames in this PPDU is Implicit BAR. This PPDU includes one or more +HTC MPDUs in which the RDG/More PPDU subfield is set to 1, indicating an RDG. The Duration/ID field of MPDUs in the PPDU contains the remaining duration of the TXOP, t0 μs.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

f) STA C (the RD responder) transmits a PPDU to STA A, containing one or more +HTC MPDUs with the RDG/More PPDU subfield set to 0, indicating that this is the last PPDU in the response burst. This PPDU contains a BlockAck frame that is a response to the implicit block ack request of the previous PPDU, plus QoS Data frames with Implicit BAR ack policy.

g) STA A (the RD initiator) regains control of the TXOP and transmits a BlockAck frame to STA C that acknowledges the MPDUs transmitted by STA C. This PPDU contains one or more +HTC MPDUs with the RDG/More PPDU subfield set to 1, indicating an RDG. The Duration/ID field of MPDUs in the PPDU contains the remaining duration of the TXOP, t1 μs.

h) STA C (the RD responder) transmits a PPDU to STA A, containing QoS data +HTC MPDUs with Implicit BAR ack policy and the RDG/More PPDU subfield set to 0. This is the only PPDU in the RD response burst.

i) STA A transmits a BlockAck frame to STA C that acknowledges the MPDUs transmitted by STA C in the RD response burst.

O.4 Illustration of determination of NDP addresses

Determination of NDP SA and DA are illustrated in Figure O-3 and Figure O-4.

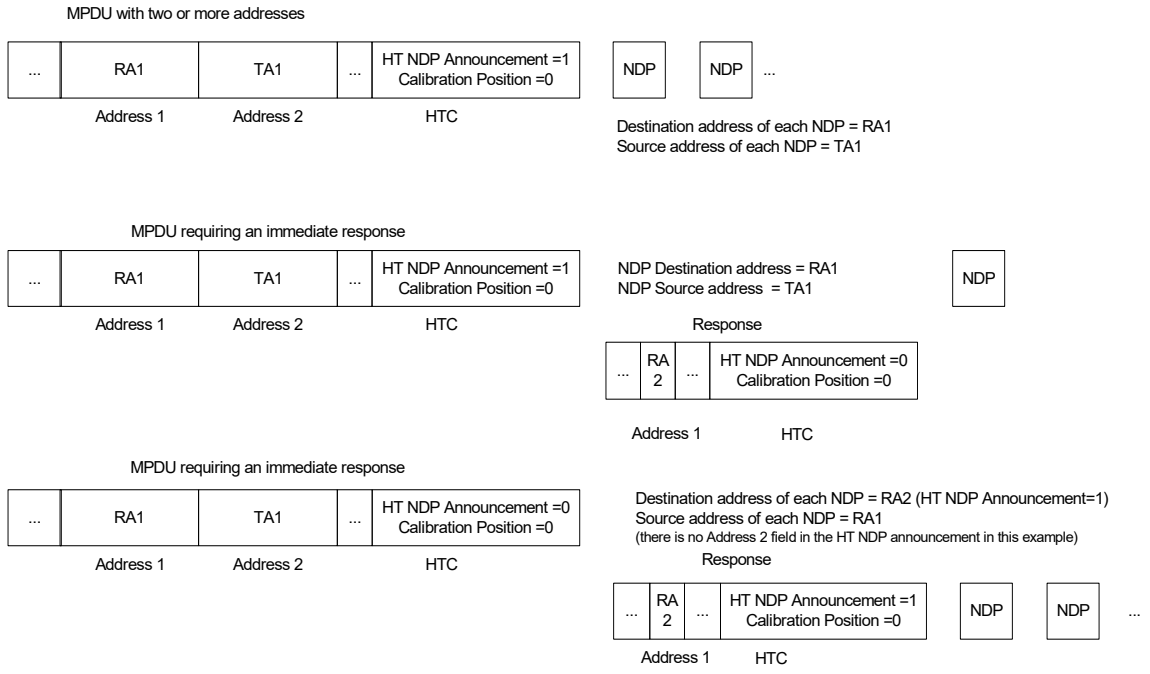

Figure O-3—Determination of NDP source and destination for unidirectional NDP sequences

Figure O-4—Determination of NDP source and destination for bidirectional NDP sequence

O.5 20/40 MHz BSS establishment and maintenance

O.5.1 Signaling 20/40 MHz BSS capability and operation

A BSS that occupies 40 MHz of bandwidth and that is administered by an HT AP is called a *20/40 MHz BSS*.

An HT AP that has dot11FortyMHzOperationImplemented equal to true sets the Supported Channel Width Set subfield of the HT Capabilities element to a nonzero value. The AP might also operate a 20/40 MHz BSS. The Supported Channel Width Set subfield of the HT Capabilities element that is transmitted by the AP indicates the possible operating mode of the BSS and of the AP, but the value in this field is not an indication of the current BSS bandwidth of either the AP or the BSS.

An HT AP signals the operating width of the BSS through the Secondary Channel offset field of the HT Operation element. A nonzero value in this field indicates that a secondary channel exists; in other words, the BSS is a 20/40 MHz BSS. A value of 0 in this field indicates that the BSS is operating as a 20 MHz BSS.

An HT AP that has dot11FortyMHzOperationActivated equal to true sets its STA Channel Width field of the HT Operation element to 1.

O.5.2 Establishing a 20/40 MHz BSS

Before starting a 20/40 MHz BSS, a 40MC HT AP is required by the rules defined in 11.15.5 to examine the channels of the current regulatory domain to determine whether the operation of a 20/40 MHz BSS might unfairly interfere with the operation of existing 20 MHz BSSs. The AP (or some of its associated HT STAs) is required to scan all of the channels of the current regulatory domain in order to ascertain the operating channels of any existing 20 MHz BSSs and 20/40 MHz BSSs. This type of scanning is called *OBSS scanning*. The particulars of OBSS scanning are controlled by the following:

— dot11FortyMHzOptionImplemented
— dot112040BSSCoexistenceManagementSupport
— dot11FortyMHzIntolerant
— dot11BSSWidthTriggerScanInterval
— dot11BSSWidthChannelTransitionDelayFactor
— dot11OBSSScanPassiveDwell
— dot11OBSSScanActiveDwell
— dot11OBSSScanPassiveTotalPerChannel
— dot11OBSSScanActiveTotalPerChannel
— dot11OBSSScanActivityThreshold

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Specific values for these MIB attributes are provided to set minimum scan times for passive scanning of each channel, and a separate minimum time is provided for active scanning of each channel. A total minimum amount of scanning per channel is required before a determination can be made to allow the operation of a 20/40 MHz BSS.

The rules that are applied when determining whether a 20/40 MHz BSS can be established are intended to avoid a full or partial overlap of the secondary channel of the 20/40 MHz BSS with an existing primary channel of either a 20 MHz BSS or a 20/40 MHz BSS. The lack of partially overlapping channels in the 5 GHz band allows these rules to be written as recommendations, while in the 2.4 GHz band, they are requirements.

An additional constraint on establishing a 20/40 MHz BSS includes the allowance for any IEEE 802.11 device to explicitly prohibit the operation of the 40 MHz operating channel width due to other considerations. For example, if an IEEE 802.15.1™ WPAN device is operating in the area, that device is likely to be unable to communicate successfully with a paired receiver if the number of available IEEE 802.15.1 WPAN channels falls below a given threshold. Operation of a 20/40 MHz BSS in the 2.4 GHz band can contribute to the reduction of the number of available IEEE 802.15.1 WPAN channels, possibly pushing the available channels below that threshold.

To promote sharing of the spectrum resource under such circumstances, it might be desirable to prohibit the operation of a 20/40 MHz BSS. As such, the 20/40 BSS coexistence mechanism allows a STA to transmit Management frames containing a value of 1 for the Forty MHz Intolerant field. (dot11FortyMHzIntolerant determines the setting of the value of the Forty MHz Intolerant field in transmitted frames, and the setting of the value of the MIB attribute is beyond the scope of this standard.) Receivers of such frames on any channel in the band are not allowed to establish a 20/40 MHz BSS anywhere in the band for a duration of dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidth-TriggerScanInterval seconds. To effect this requirement, monitoring STAs and APs maintain a countdown timer to indicate that a prohibition is in force. The countdown timer is reloaded with the value dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds each time that the STA or AP observes a Management frame containing a value of 1 for the Forty MHz Intolerant field. STAs communicate changes in their countdown counter (i.e., transitions between a zero value and a nonzero value) to their associated AP through the 20 MHz BSS Width Request field of the 20/40 BSS Coexistence Management frame.

O.5.3 Monitoring channels for other BSS operation

Some of the STAs that are associated with a 20/40 MHz BSS perform monitoring so that the conditions which allowed the establishment of the 20/40 MHz BSS do not change to conditions that would disallow the existence of the 20/40 MHz BSS.

Monitoring STAs keep a local record of channels that are in use by other BSSs. STAs that receive Beacon frames determine the primary channel by examining the DSSS Parameter Set element. Secondary channel existence and channel information are determined by examining the Secondary Channel Offset field of the 20/40 BSS Coexistence element. Monitoring STAs also record receptions of frames that contain a value of 1 for the Forty MHz Intolerant field. Any changes to the local record that would create a prohibition against 20/40 MHz BSS operation are immediately reported to the associated AP through the transmission of a 20/40 BSS Coexistence Management frame (i.e., with the 20 MHz BSS Width Request field set to 1). The reception of a 20 MHz BSS Width Request field equal to 1 at the AP causes the AP to switch the BSS to 20 MHz operation immediately.

Any change of a channel in use that had not previously been in use is also reported immediately within a 20/40 BSS Coexistence Management frame. The AP examines the new in-use channel information to determine whether any changes in BSS width operation are required (i.e., to see if any changes have

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

occurred that indicate an overlap of the secondary channel). If a change to 20 MHz BSS operation is required, the change occurs immediately.

Conditions that prevent the operation of a 20/40 MHz BSS might be transient. If the number of channels in use is reduced or all STA signaling 40 MHz intolerance leave the area, an AP might choose to revert to 20/40 MHz operation, if allowed to do so. However, the conditions that allow 20/40 MHz BSS operation have to persist for a period of dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds before a STA can signal that the conditions have changed, and the same period of time has elapsed before an AP can resume 20/40 MHz BSS operation.

STAs that do not monitor channels through OBSS scanning and do not report any channel information or received Forty MHz Intolerant field information to their associated AP are listed here:

— Non-HT STAs
— HT STAs that are exempt from scanning as specified in 11.15.6
— HT APs, once the 20/40 MHz BSS is established
— HT STAs that are associated with an AP whose BSS is operating on a channel that is not in the 2.4 GHz band
— HT STAs that are associated with an HT AP that is not a 40MC HT AP (as indicated by a value of 0 in the Supported Channel Width Set subfield of the HT Capabilities element)

All other HT STAs that are associated with a a 40MC HT AP whose BSS is operating on a channel in the 2.4 GHz band monitor channels through OBSS scanning and report any channel information or received Forty MHz Intolerant field information to their associated AP.

All MIB attributes that are employed by the 20/40 BSS Coexistence mechanism are maintained by the AP, which has the ability to provide updates to the MIB attribute values to the associated STA by transmitting an OBSS Scan Parameters element.

Annex P

(informative)

Location and Time Difference accuracy test

P.1 Location via Time Difference of arrival

The location of a device might be determined using multiple methods, including:

— Signal strength at different sensors
— Time of flight between the device and different sensors
— Time difference of arrival between the device and pairs of sensors

A typical implementation of the time difference of arrival method requires that the sensors are co-channel, have synchronized clocks, and receive the same transmission from the device. The sensor's time of arrival measurements are shared, and the device location is determined via multilateration, i.e., each pair of sensor measurements provides a time difference of arrival measurement that represents a hyperbola in 2D space of most likely candidate locations, and the overlap of the multiple hyperbola from multiple pairs of sensors leads to the location estimate. The single time of departure is not relevant in this typical multilateration implementation as it is canceled out when time differences of arrival are computed.

When the sensors are on different channels, such as APs in a typical multichannel deployment, the device transmits on each channel and thus with multiple times of departure. In this environment it is necessary for the device to advertise each time of departure so that it can be subtracted from the times of arrivals measured by sensors on different channels. Furthermore, the device's clock frequency typically does not match the clock frequency of the synchronized sensors, and so the device should transmit on the same channel multiple widely spaced times in order for the sensors to estimate the device's clock frequency relative to themselves and to be able to suitably scale the device's advertised times of departure.

An example transmission sequence comprises frames transmitted on channels 1, 6, 11, 1 at 2.4 GHz. From this, the device's clock frequency can be determined relative to the synchronized APs on channel 1, and all APs on channels 1, 6, and 11 can measure a time of arrival. These four transmissions enable a single location calculation. The Time of Departure Accuracy test in P.2 is designed to measure errors within such a transmission sequence that would degrade a multichannel time difference of arrival location scheme.

P.2 Time Difference of departure accuracy test

The Time Difference of Departure accuracy test is an informative description of how time difference of departure accuracy can be measured for any parameterizable PHY waveform. This accuracy test does not apply when the Time of Departure timestamps are exclusively used for timing measurement (see 11.21.5).

The Time Difference of Departure accuracy test is parameterized by the following test parameters:

— TIME_OF_DEPARTURE(j,i), $1 \le j \le 500$, $1 \le i \le I$ (scalar entries)
— MULTICHANNEL_SAMPLING_RATE (scalar)
— FIRST_TRANSITION_FIELD(j,i), $1 \le j \le 500$, $1 \le i \le I$ (waveform entries)
— SECOND_TRANSITION_FIELD(j,i), $1 \le j \le 500$, $1 \le i \le I$ (waveform entries)
— TRAINING_FIELD(j,i), $1 \le j \le 500$, $1 \le i \le I$ (waveform entries)
— TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH (scalar)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

TIME_OF_DEPARTURE(j,i) is exposed externally through the TOD Timestamp field in the Time of Departure subelement in Location Track Notification frames.

The Time Difference of Departure accuracy test is performed as follows or in an equivalent or more accurate manner.

The Time Difference of Departure accuracy test is performed by instrumentation capable of converting signals transmitted on one or more channels into a stream of complex samples at f_s sample/s or more, with sufficient accuracy in terms of I/Q arm amplitude and phase balance, dc offsets, phase noise, etc, and at a fixed delay from the transmitter. The minimum sampling rate is MULTICHANNEL_SAMPLING_RATE expressed in sample/s. A possible embodiment of such a setup is converting the signal to a low IF frequency with a cabled microwave synthesizer, sampling the signal with a digital oscilloscope and decomposing it digitally into quadrature components. The sampled signal is processed in a manner similar to an actual time of arrival processor, according to the following steps:

a) Repeat steps b) to j) indexed by $j = 1, \ldots, 500$
b) Repeat steps c) to i) indexed by $i = 1, \ldots, I$
c) Start of frame is detected.
d) Channel number, coarse and fine frequency offsets are estimated.
e) The packet is derotated according to estimated frequency offsets.
f) The transition from FIRST_TRANSITION_FIELD(j,i) to SECOND_TRANSITION_FIELD(j,i) is detected; and fine timing (with one sample resolution) is established.
g) The TRAINING_FIELD(j,i) of the derotated signal is upsampled to meet the TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH requirement. For example, a TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH of 1 ns requires upsampling of at least 1 GHz.
h) The up-sampled signal is cross-correlated with a reference waveform of the TRAINING_FIELD(j,i)
i) The measured time of departure $x_{j,i}$ is determined from the time of the peak of the magnitude of the cross-correlation.

NOTE 1—The time of the peak of the magnitude of the cross-correlation is actually a time of arrival measurement that equals the time of departure up to a fixed delay. Since the fixed delay is removed within step j), the fixed need not be known or explicitly compensated for.

j) Having repeated steps c) to i) I times, the (j,i)th time of departure error $e_{j,i}$ is calculated as TIME_OF_DEPARTURE(j,i) minus the synchronized time of departure. Defining $x_j = [x_{j,1}, ..., x_{j,I}]^T$ as the I measured times of departure, y = [TIME_OF_DEPARTURE(j,1), … TIME_OF_DEPARTURE(j,I)]^T, $e_j = [e_{j,1}, e_{j,I}]^T$ are the I time of departure errors and $X_j = [1_{I\times 1}, x_j]$, where $1_{I\times 1}$ is an $I\times 1$ matrix of 1s, then the relative clock intercept, rci_j, and slope, rcs_j, between device and instrumentation are determined as the linear least squares line of best fit: i.e., $[rci_j, rcs_j]^T = (X_j^T X_j)^{-1} X_j^T y^j$. With these definitions and calculations, the synchronized time of departure $s_j = [s_{j,1}, ..., s_{j,I}]^T$ equals $rcs_j \times x_j + rci_j \times 1_{I\times 1}$, and so the I time of departure errors equal $e_j = y_j - s_j$.
k) Having repeated steps b) to j) 500 times, there are $500 \times I$ values of the time of departure errors $e = [e_{1,1}, e_{500,I}]$
l) The Time Difference of Departure accuracy test is passed if both of the following conditions are met:
    1) The RMS value of e is less than aTxPHYTxStartRMS.
    2) aTxPHYTxStartRMS is less than TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH, where the units of e, aTxPHYTxStartRMS, and TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH are properly accounted for.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

NOTE 2—One possible implementation of a time of departure measurement system is a free-running oscillator clocking (a) the digital-to-analog converter(s) used to transmit the packet, (b) a 32-bit continuously counting counter, and (c) a hardware finite state machine such that PHY-TXSTART.request primitive causes a transition within the finite state machine that in turn causes frame transmission at the DACs a fixed number of cycles later; where the time of departure is recorded as the value of the counter at that transition minus aTxPHYTxStartRFDelay (using TIME_OF_DEPARTURE_ClockRate), where aTxPHYTxStartRFDelay can vary by channel. In this implementation, the principal source of time of departure error is short-term oscillator imperfection (e.g., phase noise) and RF group delay variation across channels uncompensated by aTxPHYTxStartRFDelay.

NOTE 3—One ns of time of departure error corresponds to approximately 0.3 m of distance error, so high location accuracy depends upon a tight time of departure standard deviation.

P.3 Differential Distance Computation using FTM frames

In Figure P-1 the Observing STA is able to listen to the FTM frame exchange between the Sending and Receiving STAs. The time of flight of a line of sight transmission between the Sending and Receiving STAs is denoted as T. At the Observing STA, the time of arrival (TOA) of message M and its Ack frame are respectively t_{c1} and t_{c2}. At the Sending STA, the time of departure (TOD) of message M and the TOA of its Ack frame are t_1 and t_4 respectively.

The differential distance between the Observing STA and each of the Sending and Receiving STAs, denoted as D_{SR}, is defined as:

$$D_{SR} = c \times (T_{SO} - T_{RO} \tag{P-1}$$

where

c is speed of the light.
T_{SO} is the time of flight between the Sending STA and the Observing STA
T_{RO} is the time of flight between the Receiving STA and the Observing STA

D_{SR} can now be computed as:

$$D_{SR} = c \times (t_{c1} - t_{c2} - T - (t_1 - t_4)) \tag{P-2}$$

An Observing STA can use the TOA and the time stamps (t_1 and t_4) received in the following messages in the message exchange to refine its computation of the differential distance to the Sending and Receiving STAs.

In Figure P-1 the Receiving and Sending STAs can be APs. The APs can learn about neighboring APs that support the FTM procedure and an AP can initiate an FTM message exchange on a periodic basis (e.g., the beacon interval or a multiple of the beacon interval) with its neighbor APs. Monitoring and receiving these messages can enable Observing STAs to estimate their differential distance with the AP pairs. An Observing STA that is able to determine its differential distance to at least three pairs of Sending and Receiving STAs can determine its location using the principle of hyperbolic navigation. An Observing STA can potentially determine its location by monitoring the FTM frames of a single AP (Sending STA) if there are three or more neighbor APs of the Sending STA that support FTM.

Figure P-1—Parameters recorded by Observing STA when monitoring FTM frames

In Figure P-2 the observing or passive STA (PSTA) that supports NGV non-TB ranging is able to listen to the NGV non-TB ranging measurement exchange between an initiating STA (ISTA) and a responding STA (RSTA). The time of flight of a line of sight transmission between the ISTA and RSTA is denoted as *T*.At the PSTA, the TOAs of the I2R NDP and the R2I NDP are respectively t_{c1} and t_{c2}. At the ISTA, the TOD of the I2R NDP and the TOA of the R2I NDP are t_1 and t_4, respectively. D_{SR} can now be computed according to Equation (P-2). The PSTA might obtain t_1 and t_4 by receiving the I2R LMR frame or by higher layer information exchange.

Annex Q

(informative)

Example use of the Destination URI for Event and Diagnostic Reports

Q.1 Destination URI payload

An example of the payload used to transmit Event and Diagnostic reports shown in Table Q-1. The protocol used to transport the Destination URI payload is beyond the scope of this standard. An example use of the Destination URI is given in Q.2.

Table Q-1—Destination URI payload

Size (octets)	Information
6	BSSID
6	Reporting STA Address
variable	Event or Diagnostic Report frame contents

Q.2 Use of HTTP (or HTTPS) for Destination URI of Event and Diagnostic Reports

Under certain conditions a non-AP STA might need to send Event and Diagnostic reports to an AP using the Destination URI advertised by the AP in the request frame. A suitable higher layer protocol that could be used to transport the Event or Diagnostic report is HTTP or HTTPS.

For example, consider the following:

1) IT is investigating a WLAN coverage problem and uses a non-AP STA with a WLAN and Ethernet adapters to collect some additional information.
2) The non-AP STA with MAC 00-ff-fd-00-00-01 has received a request for a Diagnostic report from AP 00-ff-fe-00-00-10 and is in fringe coverage. The non-AP STA has an Ethernet adapter that is connected.
3) The AP includes an Alternate Destination URI of http://www.myserver.mycompany.com in the Diagnostic Report frame.
4) The non-AP STA loses WLAN connectivity while trying to transmit a Diagnostic Report frame to the AP and the non-AP STA's SME determines that it can use the Alternate Destination URI to send the Diagnostic Report frame using the Ethernet link.
5) The non-AP STA POSTs the Diagnostic report as follows:
   POST /wnm/msg/00-ff-fd-00-00-01/msg1 HTTP/1.1
   Host: http://www.myserver.mycompany.com
   Content-Type: application/octet-stream
   Content-Encoding-Type: base64
   Content-Length: i (length of data as specified in Figure 9-1271 in 9.6.13.5)
   <encoded data = 00 ff fe 00 00 10 00 ff fd 00 00 01 …>

In the HTTPS case, the non-AP STA would need to be provisioned with credentials to establish the TLS connection prior to posting the message over HTTP. The HTTP post would work as described previously.

Annex R

(informative)

Interworking with external networks

R.1 General

The purpose of this informative annex is to describe and clarify the support for interworking with external networks including the support for network discovery and selection, QoS mapping, SSPN interface, and emergency services and to provide some background information and recommended practices.

R.2 Network discovery and selection

R.2.1 General

Interworking service provides features to support the network discovery and selection process a STA uses to choose the network with which to associate. GAS provides a non-AP STA access to an advertisement server (e.g., an IEEE 802.21 Information Server), which can provide a rich set of information to aid the network discovery and selection process. In addition, interworking service provides lightweight features that also facilitate this process. The following subclauses describe several use cases illustrating how these features can be used to aid in network discovery and selection:

— **Airport:** A traveling businessperson needs to connect via an airport hotspot to their enterprise network to download email and information from the customer database.
— **Shopping:** A shopper visits a shopping mall and wants to use a smartphone to discover items on sale.
— **Sales meeting:** A salesperson visiting a customer accesses their guest network.
— **Museum:** A visitor to a museum uses a smartphone to obtain virtual docent service.
— **Emergency call:** A traveler needs to make an emergency call while in another country.
— **Emergency alert:** A traveler, having enabled the display of emergency alerts, arrives at a new destination.

R.2.2 Airport

A traveling businessperson arrives for the first time at an airport having a WLAN. This user wants to download email onto their laptop utilizing the airport's hotspot, a chargeable network. Once associated, the user needs to connect via VPN connection back to their company's servers to access email and information from the customer database. This is performed as follows:

a) The laptop's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to "Chargeable Public Network." In response, it receives Probe Response frames from several of the airport's APs, in the immediate neighborhood, for the SSID "Narita Hotspot."
b) The Probe Response frame received by the laptop indicated the following capabilities:
    1) Extended Capabilities element indicates: AP provides interworking service.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

2) Interworking element indicates: venue group = 1 (Assembly) and venue type = 3 (passenger terminal), Internet = 1 (Internet access available), ASRA = 1 (there is an additional step required for network access).
3) Advertisement Protocol element including the Advertisement Protocol ID field set to MIS Information Service.
4) Roaming Consortium element present containing an OI for "Hotspot Roaming International."
5) There is no RSNE present in the received Beacon frame.

c) Since the laptop's SME does not recognize the Roaming Consortium OI, it invokes the GAS protocol to query the network's IEEE 802.21 information service. The IEEE 802.21 Information Server's response indicates the roaming partners for "Narita Hotspot" and the laptop have security credentials for one of them.

d) Since the AP indicated ASRA = 1, the SME again invokes the GAS protocol to retrieve the Network Authentication Type ANQP-element. The response indicates that https redirection is in use and provides the redirect URL of hotspot.narita.co.jp. Note that this is helpful since some networks use conditional redirection—that is, access to a walled garden is provided for free, but a subscription fee is required to access the Internet.

e) In large federations (where multiple venues may allow for multiple sources of identities) using Roaming Consortium OI, the multi-to-multi relationship makes it difficult for the STA to understand which credentials from which members of the consortium are actually accepted by the venue. Beyond posing restrictions on the source of credentials, the venue may also mandate a level of robustness for these credentials. The credentials may then only be accepted if the entity providing them has validated the user identity reliably. When validation is light, credentials that have been in existence for a long time may be seen as more reliable than credentials that were created very recently. Last, the venue may have legal requirements to receive a contactable identity for each user. Since the AP has advertised a Roaming Consortium OI, the laptop SME invokes the GAS protocol to retrieve the Credential Types ANQP-element:
1) The AP response indicates, in the Credential Types ANQP-element, two Credential Types subfields, the first indicating Category Group = 12, Category Type = 1 (Service Provider), Validation = 2 (email, SMS, Government ID or Government issued credentials), Lifetime = 0 (account has been in existence for any duration) and Privacy Indicator = 1 (contactable identity required), the second indicating Category Group = 12, Category Type = 2 (Cloud or Social Media Provider), Validation = 4 (Government ID or Government issued credentials), Lifetime = 4 (account has been in existence for one year or more) and Privacy Indicator = 1 (contactable identity required).
2) The laptop now knows which credentials types are accepted.

f) Venues accepting several types of credentials may have agreements to provide different level of service for different types of users. These levels of services are usually agreed upon at a large scale (e.g., all members of a federation), and thus use a common naming convention (Gold, Silver, Bronze). Since the AP has advertised a Roaming Consortium OI and support for Service Level Agreement information, the laptop SME invokes the GAS protocol to retrieve the Service Level Agreement ANQP-element. The AP response indicates: First Settlement Indicator = 1 (free services), First SLA Indicator = 1 (Bronze), Second Settlement Indicator = 2 (paid services), Second SLA Indicator = 2 (Silver). The laptop can then select, from the profiles with accepted credentials, those that also accept the SLA offered by the venue.

g) Since the laptop's SME now knows it should be able to successfully authenticate with the network, the STA associates with the AP.

h) The following operations are then carried out by higher layers operating within the laptop:
1) The laptop's SME autonomously launches an http client and provides to it the URL of hotspot.narita.co.jp, which provides the proper security credentials to the network and thereby successfully authenticates it to the network.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

2) The VPN client is autonomously launched and a secure session to the user's corporate network is established. Then the user launches the email application to download email and other required information.

R.2.3 Shopping

A shopper visits a shopping mall and wants to use a smartphone to discover items on sale. In this mall, the mall's IT department is providing WLAN facilities for all of the stores in the mall; therefore, there is only one SSID for shoppers (i.e., there is not a different SSID for each store in the mall). The user arrives at the mall and taps an icon on the screen to put the smartphone in "shopping mode." The smartphone's shopping application causes the non-AP STA to carry out the following steps:

a) The smartphone's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to "Free Public Network." In response, it receives Probe Response frames from several of the mall's APs, but only one SSID is provided, which is "Silicon Valley Mall." The mall's APs did not transmit Probe Response frames for the SSIDs "Engineering," "Deliveries," and "Janitorial" since their access network type is "Private network."

b) The Probe Response frame received by the smartphone indicated the following capabilities:
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Interworking element indicates: venue group = 6 (mercantile) and venue type = 4 (shopping mall), Internet = 0 (unspecified).
   3) RSNE indicates: IEEE 802.1X authentication.

c) Since the AP indicated Interworking service is available, the smartphone's non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 9.4.5.3). In the Capability List ANQP-element, the AP has indicated support for the Venue Name, Domain Name, and Excluded NAI Realm ANQP-elements. Subsequent to receipt of the Capability List ANQP-element, the non-AP STA invokes the MLME-GAS.request primitive to retrieve the other lists.

d) Next, the non-AP STA's Supplicant searches the received domain name list to determine whether it has any stored credentials for these domains.

e) In some cases, the venue may also not accept credentials from competing entities. Therefore, the non-AP STA's Supplicant also searches the list of excluded NAI realms to determine which realm credentials are not accepted. The non-AP STA discards the credentials that match elements of the excluded NAI realm list returned by the AP. If the non-AP STA finds accepted credentials,
   1) The smartphone autonomously associates with the "Silicon Valley Mall Shopping" SSID and displays the following information:
      i) Venue name: Silicon Valley Mall, 1234 Main Street, Rownhams, CA 98765-1234
      ii) SSID: Silicon Valley Mall
      iii) Venue type: Shopping Mall
   2) The Supplicant autonomously provides the security credentials for the selected domain.

f) Higher layer protocols then download discount coupons being offered for items on sale.

R.2.4 Sales meeting

A salesperson travels across town to a meeting at ACME Manufacturing. While there, this user needs to send email to get a document from engineering. The user requests WLAN guest access via their laptop's UI to search for guest networks. The laptop performs the following steps:

a) The laptop's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to "Pri-

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

vate Network with Guest Access." In response, it receives Probe Response frames from several of ACME Manufacturing's APs, but only one SSID is provided, which is "Guest." ACME Manufacturing's APs did not transmit Probe Responses for the SSIDs "Engineering" and "Finance" since their access network type is "Private network."

b) The Probe Response frame received by the laptop indicated the following capabilities:
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Interworking element indicates: Internet is available, venue group = 2 (Business) and venue type = 8 (Research and Development Facility).
   3) RSNE indicates: IEEE 802.1X authentication with CCMP-128 pairwise, group data cipher suites, and group management cipher suite.

c) Since the AP indicated interworking service is available, the laptop's non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 9.4.5.3). In the Capability List ANQP-element, the AP has indicated support for the Venue Name ANQP-element. Upon receipt of the Capability List ANQP-element, the non-AP STA again invokes the MLME-GAS.request primitive to retrieve the venue name.

d) The laptop's UI displays the following information and automatically associates with the network:
   1) SSID: Guest (Type: Private network with Guest access)
   2) Venue name: ACME Manufacturing, 1234 Main Street, Rownhams, CA 98765-1234
   3) Venue type: Research and Development Facility
   4) Internet is available

e) Upon prompt, the user enters the username and password supplied by their point of contact from ACME Manufacturing and is then able to send and receive email.

R.2.5 Museum

A visitor enters a museum that is advertising virtual docent service (audio tracks describing each of the major exhibits). The visitor taps an icon on a smartphone and requests it to search for free networks. The smartphone then carries out the following:

a) The smartphone's non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element with Access Network Type subfield set to "Free Public Network." In response, it receives Probe Response frames from several of the museum's APs, but only one SSID is provided, which is "Visitors." The museum's APs did not transmit Probe Response frames for the SSID "Maintenance" since its access network type is "Private network."

b) The Probe Response frame received by the smartphone indicated the following capabilities:
   1) Extended Capabilities element indicates: AP provides interworking service.
   2) Interworking element indicates: venue group = 1 (assembly), venue type = 9 (museum), and ASRA = 0 (no additional steps are required for access).

c) Since the AP indicated interworking service is available, the smartphone's non-AP STA uses the MLME-GAS.request primitive to invoke GAS to request the Capability List ANQP-element (see 9.4.5.3). In the Capability List ANQP-element, the AP has indicated support for the Venue Name ANQP-element. Upon receipt of the Capability List ANQP-element, the non-AP STA again invokes the MLME-GAS.request primitive to retrieve the venue name.

d) The smartphone's UI displays the following information, asking the user whether they wish to connect to the network:
   1) Venue name: Museum of Modern Art (MOMA)
   2) SSID: Visitors
   3) Venue type: Museum

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

4) No authentication required

e) The user taps the “Connect” icon on the smartphone’s display. Note that the smartphone’s non-AP STA knows that the network uses Open System authentication since there is no RSNE present in the beacon and ASRA = 0.

R.2.6 Emergency call

A traveler needs to make an emergency call while in another country. The traveler might not be aware of the emergency call numbers that are used in that country. Being in this new location for the first time, the traveler is not aware of which local access points provide access for emergency calling. (Note that emergency calling requires higher layer application(s) that are outside the scope of this standard.) This is performed as follows:

a) The traveler’s non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID and an Interworking element. (If the non-AP STA is already associated with an AP that has indicated support for emergency service in its beacon, the probe request would not be necessary.)

b) In response, it receives Probe Response frames from one or more APs indicating support for emergency service in the Access Network Options field of the Interworking element.

1) Extended Capabilities element indicates: AP provides interworking service.

2) Emergency services reachability is indicated by the ESR and UESA fields in the Access Network Options field in the Interworking element.

3) A dedicated emergency services network is indicated by the Access Network Type field in the Interworking element.

c) The traveler’s non-AP STA then requests the Emergency Call Number ANQP-element with a GAS Initial Request frame.

d) The GAS Initial Response frame from the AP provides the Emergency Call Number, for example the sequence of digits “911” or an emergency service URN label, URI pair “urn:service:sos.fire, tel:112;sip:+15555551002@fire.com” (IETF RFC 5031 [B46]).

e) This information is passed to the higher layer application in the traveler’s non-AP STA.

f) The traveler’s non-AP STA then associates with the AP.

g) The traveler’s non-AP STA then places the emergency call, with an Expedited Bandwidth Request element in an ADDTS Request frame to provide priority to the emergency call.

R.2.7 Emergency alert

A traveler has enabled the display of emergency alerts on a wireless device (non-AP STA) by appropriately setting the higher layer emergency alert application on the device. The traveler arrives at a new destination and turns on the device. The device, when switched on, will perform a search and then associate with an AP to which the traveler has a subscription or associate with an open AP (if the traveler has enabled the device to do that). During the steps leading up to association, the device, when it becomes aware of an emergency alert, will obtain and display it. The emergency alert will likely be obtained from the AP that has the service to which the traveler has subscribed, but the device might also obtain the emergency alert from other APs, if an AP to which the traveler has a subscription is not available. This is performed as follows:

a) The traveler’s non-AP STA performs an active scan by transmitting a Probe Request frame containing the wildcard SSID. If it is associated with an AP, it checks the beacon.

b) In response, it receives Probe Response frames from one or more APs, which it checks (or, alternately, checks the beacon) for the subscription and also whether the Emergency Alert element indicates that there are emergency alert message(s).

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

c) If there are one or more emergency alert messages to be downloaded, the Emergency Alert Identifier element provides an Alert Identifier Hash value.

d) The device uses the hash of each of the available emergency message(s) to determine whether that message has already been received or whether it is a new message that needs to be downloaded.

e) If there are one or more emergency alert messages to be downloaded, the device forms the EAS Message URI by concatenating the Emergency Alert URI with the hexadecimal numerals of the Alert Identifier Hash, using the specified method.

f) Should the device be unassociated with an AP when it determines that a new emergency alert is available, it retrieves the EAS message using either GAS procedures with the Advertisement Protocol ID field set to the value for EAS. If the device is associated with the AP, it retrieves the EAS message using either GAS procedures with the Advertisement Protocol ID field set to the value for EAS or, for example, using HTTP.

R.3 QoS mapping guidelines for interworking with external networks

R.3.1 General

The EDCA and HCCA mechanism defined in 10.23 provide QoS control at the MAC sublayer. However, the QoS control parameters used by the EDCA and HCCA cannot match directly with other QoS control parameters of the interworked external networks, e.g., SSPN. For example, the SSPN could have different metrics for defining the QoS levels. Destination Network 1 (DN1) and DN2 can use DSCP values differently, in which case STA1 and STA2 would require different QoS mapping information. Therefore, mapping from these external QoS control parameters to the QoS parameters of this standard is necessary.

The QoS parameters mapping can be used for both uplink and downlink data transmission:

— For uplink: at the non-AP STA, external QoS parameters are mapped to IEEE 802.11 QoS parameters, e.g., DSCP to IEEE 802.11 User Priority and in turn to EDCA ACs. This mapping helps the non-AP STA to construct correct QoS requests to the AP, e.g., the ADDTS Request frame and to transmit frames at the correct priority.

— For downlink: at the AP, DSCP values are mapped to EDCA UPs. Optionally, the non-AP STA can use TSPEC and TCLAS elements in an ADDTS Request frame to set up a traffic stream in the BSS. In this method, the User Priority is specified in the TCLAS element. The policy used by the AP to choose a specific method to map frames to user priorities is outside the scope of this standard.

Different external networks can use different DSCP sets for the same services as described in R.3.3 (QoS mapping and GLK). For example, a 3GPP network can use different code points from that of an enterprise network. The QoS Map distribution mechanism defined in 11.22.9 provides means to communicate to the STA's mapping information from the network. The mapping of the DSCP to 3GPP Traffic Class is available in GSMA IR.34 v4.6 [B13] (similar to that of GSMA IREG34). See TR 21.905 [B1] for definition of general packet radio service (GPRS) roaming exchange. Enterprise networks use mapping based on application classes defined in IETF RFC 4594 and their mapping to IEEE 802.11 UPs defined in IETF RFC 8325. Mapping between DSCP and UP can be done using Exception fields or by range. The use of DSCP Exception fields maps a DSCP to a UP. Mapping by range requires the setting of DSCP ranges as per the format defined in 9.4.2.93.

R.3.2 Determination of the mapping for a STA

The QoS mapping to be applied depends upon the network the non-AP STA is accessing. In an interworking IEEE 802.11 infrastructure setting, the APs can serve non-AP STAs from different SSPNs on different BSSIDs. As such, these STAs are separated into different BSSs. Figure R-1 presents an example of the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

scenario of an AP using authentication, authorization, and accounting (AAA). In Figure R-1, AAA Server 1 controls access to DN-1 and AAA Server 2 controls access to DN-2.

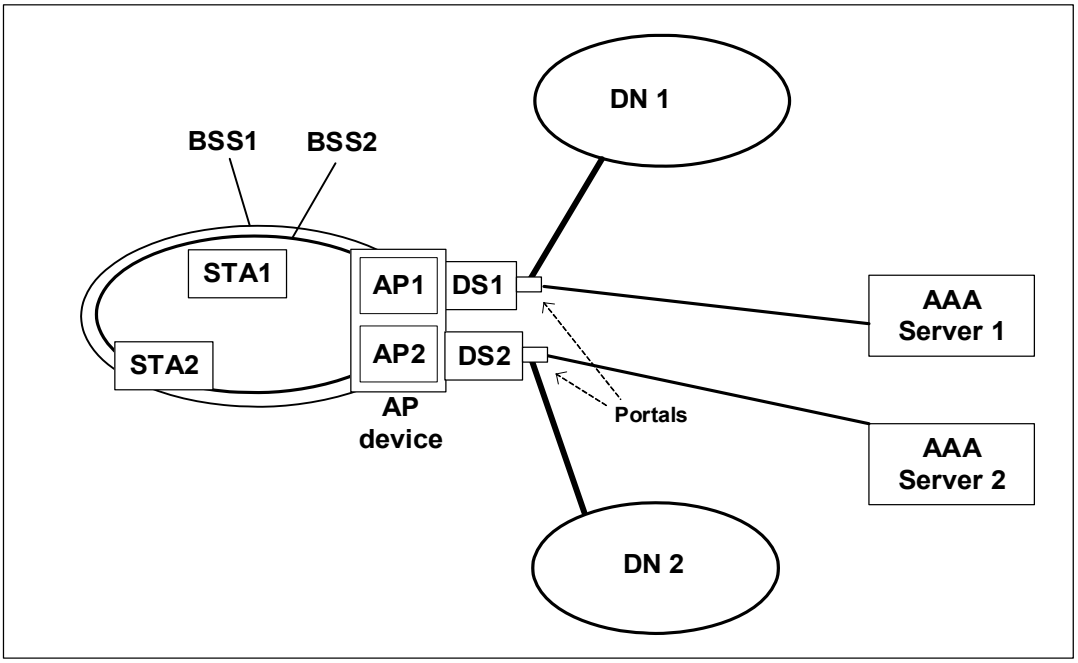

Figure R-1—Interworking IEEE 802.11 infrastructure supporting multiple SSPNs

R.3.3 QoS mapping and GLK

General links connect through a STA to an IEEE 802.1AC Internal Sublayer Service instance.
NOTE —Suggested default UPs differ from IEEE 802.1Q suggested default priorities. For example, in IEEE Std 802.11, priority 2 is lower than priority 0 while in IEEE Std 802.1Q it is higher.

The priority provided to the MS SAP by the GLK Convergence Function is the UP for the IEEE 802.11 MSDU being transmitted. As provided in IEEE Std 802.1AC-2016, the GLK Convergence Function derives this UP from the priority code point associated with the frame inside the IEEE 802.1Q bridge. A suggested mapping is given in Table R-1. The GLK Convergence Function might be configured to provide other mappings.

Table R-1—Suggested default priority code point to UP mapping

R.4 Interworking and SSPN interface support

R.4.1 General

The interworking service architecture defines the scope of the SSPN interface. This interface is provided by the IEEE 802.11 MAC to support the interworking service. In an interworking scenario, the IEEE 802.11 infrastructure is operating in infrastructure mode.

Figure R-2 shows an example implementation of the control aspect of the Interworking Interface. As shown in the figure, the Interworking Interface consists of two parts: the generic SSPN Interface between the AP and the AAA Client; and the AAA Interface between the AAA Client and the corresponding AAA Server in the SSPN. Depending on the implementation the AAA Client can be colocated with the AP or stand alone serving as a proxy or translation agent between the SSPN Interface and AAA Interface. The AAA Interface serves as a transparent carrier of the SSPN interface.

The possible interactions over the SSPN interface are defined in 11.22.5. The information transferred over the SSPN Interface is defined in R.4.2. This interface results in parameters being set in the dot11InterworkingTable. The AP's SME thereafter uses these parameters to permit or deny, as appropriate, services to non-AP STAs.

R.4.2 SSPN interface parameters

The SSPN Interface parameters are stored in the AP with corresponding MIB attributes as defined in Annex C, and are used by the Interworking Service Management function in the SME. The MIB attributes themselves, which are used by the AP SME, are read only.

R.4.2.2 Non-AP STA MAC

This parameter is the MAC address of the non-AP STA accessing the interworking service through the AP. It can be requested by the external network, e.g., a 3GPP network, for fraud prevention. The non-AP STA MAC address is normally available through MLME SAP, e.g., MLME-ASSOCIATE.indication primitive, and should be forwarded by the AS to the AAA Server entity in the SSPN through the AAA Interface.

The following is used:

— dot11NonAPStationMacAddress

R.4.2.3 Non-AP STA User ID

This parameter contains the subscriber information of the non-AP STA for the interworking service. It is provided by the non-AP STA through the RSNA establishment process to the AAA Server; in turn, the AAA Server provides it back to the AP via the SSPN interface. It is in the form of an NAI, i.e., it contains both the user's identity and its SSP information.

NOTE—The reason the AAA Server provides the user identity back to the AP is that some EAP methods use encrypted tunnels to maintain confidentiality of the user and thus the AP might not otherwise be able to learn the user's identity.

The following is used:

— dot11NonAPStationUserIdentity

R.4.2.4 Non-AP STA Interworking Capability

This parameter is derived from the non-AP STA's Extended Capabilities element, which is included in (Re)Association Request frames.The AP SME obtains this information from the MLME SAP, e.g., MLME-ASSOCIATE.indication primitive. This information needs to be passed over the SSPN interface since the service authorization decisions can depend on the non-AP STA capabilities.

The following is used:

— dot11NonAPStationInterworkingCapability

R.4.2.5 Link Layer Encryption Method

This parameter indicates the link layer encryption method selected during the RSNA establishment process for protecting the pairwise communication between the non-AP STA and the AP. The cipher suite format of this parameter is drawn from the RSNE defined in 9.4.2.23. The AP obtains this information about the STA via the MLME SAP.

In the interworking service, the SSPN also participates in the selection of the cipher suite selection, as described in 11.22.5 (Interworking procedures: interactions with SSPN). Therefore, the link layer encryption method selected will meet or exceed the security requirement of the SSPN.

NOTE—In interworking, the SSPN can require visibility and configurability of the STA access.

With this information available to the SSPN, the operator would be able to have better control, e.g., barring access to IEEE 802.11 networks if null encryption is used. This is also related to the operator network's configuration, e.g., if preauthentication should be supported.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The following is used:

— dot11NonAPStationUnicastCipherSuite

R.4.2.6 Authorized Priority

This parameter is used for admission control and user priority policing at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. The Authorized Priority specifies the authorized User Priorities that the non-AP STA is allowed to use during the Interworking access. It also specifies whether the non-AP STA can use HCCA.

For EDCA operation, the following is used:

— dot11NonAPStationAuthAccessCategories after mapping the priority according to Table 10-1.

For HCCA operation, the following is used:

— dot11NonAPStationAuthHCCAHEMM

R.4.2.7 Authorized Maximum Rate

This parameter is used for admission control decisions or policing actions at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. For EDCA operation, this parameter contains a list of four MaxRate values indicating the maximum rate allowed for each of the access categories. For HCCA operation, there is one MaxRate value. Each of the MaxRate values is an unsigned integer in kb/s. An additional value provides the maximum rate at which a non-AP STA can source group addressed frames.

The following are used:

— dot11NonAPStationAuthMaxVoiceRate,
— dot11NonAPStationAuthMaxVideoRate,
— dot11NonAPStationAuthMaxBestEffortRate,
— dot11NonAPStationAuthMaxBackgroundRate,
— dot11NonAPStationAuthMaxHCCAHEMMRate
— dot11NonAPStationAuthMaxSourceMulticastRate.

R.4.2.8 Authorized Service Access Type

This per-non-AP STA parameter indicates the access type allowed for the non-AP STA based on the SSPN decision. The AP uses this information for authorization requests from the STA, e.g., allow or disallow direct link operation and group addressed services. The parameter uses truth values to indicate the service type authorized.

The following is used:

— dot11NonAPStationAuthMaxSourceMulticastRate is to authorize a non-AP STA to source group addressed stream(s) to toward the network

R.4.2.9 Authorized Delay

This parameter is used for admission control decisions at the AP. It is based on the Infrastructure Authorization Information delivered from the SSPN during the AAA procedure. This parameter is used only for HCCA operation, and contains one value. An AP should deliver frames to a non-AP STA within the time period specified in this attribute. Furthermore, when a non-AP STA requests admission control, the

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

requested delay is approved only if it is greater than or equal to the value stored in the corresponding parameter. Each parameter is an unsigned integer that measures delay in units of microseconds.

The following is used:

— dot11NonAPStationAuthHCCAHEMMDelay

R.4.2.10 Authorized Service Access Information

This parameter contains the relevant information for the AP to enforce the authorized service access type indicated in the Authorized Service Access Type parameter. The Authorized Service Access parameters provide the VLAN assignment (VLAN ID and VLAN Name) to which frames to or from the non-AP STA are bridged.

The following are used:

— dot11NonAPStationVLANId
— dot11NonAPStationVLANName

R.4.2.11 Non-AP STA Transmission Count

This parameter indicates the count of the data traffic transmitted to and received from a non-AP STA. Such information would be used by the on-line charging and accounting function, especially for the IEEE 802.11 WLAN local service, where the data traffic does not necessarily go through the SSPN network. In such cases, Layer 3 accounting/charging information is not reliable since addresses could be spoofed. Layer 2 would be a better place to collect such information since due to the cryptographic security association that exists between the non-AP STA and AP.

The following are used:

— dot11NonAPStationVoiceMSDUCount,
— dot11NonAPStationVideoMSDUCount,
— dot11NonAPStation-BestEffortMSDUCount,
— dot11NonAPStationBackgroundMSDUCount,
— dot11NonAPStationHCCAHEMMMSDUCount,
— dot11NonAPStationMulticastMSDUCount,
— dot11NonAPStationVoiceOctetCount,
— dot11NonAPStationVideoOctetCount,
— dot11NonAPStationBestEffortOctetCount,
— dot11NonAPStationBackgroundOctetCount,
— dot11NonAPStationHCCAHEMMOctetCount,
— dot11NonAPStationMulticastOctetCount

R.4.2.12 Non-AP STA Location Information

This parameter provides information about the STA's location to the SSPN. It is required by the SSPN applying location based service control. In the IEEE 802.11 network, the non-AP STA location is approximated using the AP's location information. This parameter includes two type of formats, Geospatial and Civic Location.

The following are used:

— dot11APLCITable,

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

— dot11APCivicLocationTable

R.4.2.13 Non-AP STA State Information

This parameter indicates whether the power management mode of the non-AP STA is either active mode or PS mode.

The following MIB attribute is used:

— dot11NonAPStationPowerManagementMode

R.5 Interworking with external networks and emergency call support

R.5.1 General

Emergency services define the IEEE 802.11 functionality to support an emergency call (e.g., E911) service as part of an overall multi-layer solution, specifically capability advertisement and access to emergency services by STAs not having proper security credentials. “Multi-layer” indicates that emergency services will be provided by protocols developed in part by other standards bodies; see IETF RFC 7406 [B52], 3GPP TS 23.167 [B3], and 3GPP TS 22.067 [B2]. Three features of interworking with external networks support emergency call services.

The first feature is a mechanism for a non-AP STA to signal to an AP that a call is an emergency call. This is useful in the case where the access category to be used to carry the emergency call traffic (typically AC_VO) is configured for mandatory admission control. If the WLAN is congested, then the AP can deny the TSPEC request for bandwidth to carry the call. However, if the AP is able to determine that the call is an emergency call, then it can invoke other options to admit the TSPEC request.

The second and third features provide the means for a client without proper security credentials to be able to place an emergency call. The second feature makes use of the Interworking element, which can be included in Association Request frames in order to bypass the IEEE 802.1X port at an AP for unauthenticated access to emergency services. This is described further in R.5.5. The third feature makes use of an SSID configured for Open Authentication to provide emergency services and is described in R.5.3.

The STA has the burden to confirm the availability of emergency services from the IEEE 802.11 network, including that the network is authorized for emergency services. The time it takes for a client to find an authorized emergency services network is related to the speed of forward progress the authorized network can make over the air with the STA, relative to all of the other networks (attackers as well), and is inversely related to the number of false advertisements. A STA can confirm the availability of emergency services by observing the value of the access network type, ESR and UESA fields in the Interworking element of any received Beacon or Probe Response frame.

R.5.2 Background on emergency call support over IEEE 802.11 infrastructure

Special handling for emergency service calls is required over IEEE Std 802.11. To use a public hotspot a user will go typically through an authentication process (e.g., EAP-based, or http/https redirect or DNS redirection) before being able to use it for emergency calls.

There is a need to support these emergency services both when the user has a relationship with the IEEE 802.11 network (credentials to access the network) and when it does not have any relationship with the IEEE 802.11 network.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

The former case requires no changes to the authentication process—the user, having already been authenticated to and associated with the WLAN, simply dials the emergency number thereby placing the call.

In the latter case, the non-AP STA will be able to gain access to the network without using security credentials and make an emergency call.

Another difficulty is that once the user gains access to the network, there is no mechanism to prioritize their emergency traffic in the IEEE 802.11 MAC over that of other users, even with IEEE 802.11 QoS capability.

Supporting emergency services, such as E911 calling, requires a multi-layer solution with support at various protocol layers. Apart from MAC-level access and support for transfer of data between non-AP STA and AP with appropriate QoS at layer 2, there is a clear need, above this layer, to set up the call, conduct call control and management, and use an appropriate audio codec.

One specific example is when a user arrives in a new country and needs to make an emergency call in a public hotspot where there is no prior relationship with the available WLAN or WLAN hotspot operator.

NOTE—The callback feature, if required in a regulatory domain, is dealt with at a higher layer.

R.5.3 System aspects for emergency call support

An IEEE 802.11 infrastructure by itself cannot ensure that all factors are compatible for an emergency service call to actually take place. The client device might have to register with a call manager (SIP agent or some other signaling endpoint) for the call to be placed successfully. Different signaling systems such as SIP, H.323, etc., can be deployed for supporting emergency service calling. Higher layers can also verify an emergency service call is being placed so that appropriate level of resources can be granted to the emergency call. Voice endpoints (e.g., non-AP STAs) can use different codecs such as G.711, AMR, and iLBC. All these functionalities are outside the scope of this standard.

IEEE Std 802.11 can provide priority for emergency traffic both for the initial call establishment and during an ongoing emergency call, which assumes advertisement of this functionality supported in the BSS.

This subclause describes general design assumptions to support emergency services with IEEE Std 802.11:

a) It is assumed that there is a higher layer (above IEEE 802.11 Layer 2) protocol (or protocol suite) for making emergency calls or using any other emergency services.
b) In order to make the emergency call procedure work properly, the non-AP STA has the following responsibilities:
    1) Recognize the user’s request to make an emergency call.
    2) Select an AP that supports QoS and expedited bandwidth request capability.
    3) Non-AP STA will associate with the AP if it is not already done so. In an RSN, if the user does not have valid authentication credentials for network access then non-AP STA can bypass the RSN that will provide access to the network to make emergency calls.
    4) If location information is required in a particular regulatory domain, request location information from the WLAN. If the STA cannot determine its own location by its own means, then Location information should be obtained from the network prior to initiating the emergency call request. There are two methods a non-AP STA can use to obtain location services from the IEEE 802.11 network:
        i) If the non-AP STA can use location information in geospatial format (i.e., latitude, longitude and altitude), then the LCI report procedures (11.10.9.6) can be used to obtain this information. The AP advertises its capability for the LCI report procedures by setting the LCI Measurement Capability Enabled field to 1 in the RM Enabled Capabilities field

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

in the RM Enabled Capabilities element, and the non-AP STA transmits an LCI request to the AP.

NOTE—The non-AP STA can receive an LCI report with the incapable field set. According to the procedures in 11.10.9.6, the non-AP STA can resubmit an LCI request with a location subject of "remote." If the AP still responds with incapable, then location services are not available from the AP via the LCI report procedures.

ii) If the non-AP STA requires location information in Civic or geospatial formats, then an AP's wireless network management capability can be used. In this case, an AP advertises its ability to provide its location in Civic or geospatial format by setting the Civic Location or Geospatial Location field in the Extended Capabilities element to 1 respectively in the Beacon frame. A non-AP STA can also request its location using the procedures in 11.22.7. An AP that advertises its ability to provide its location in civic or geospatial format does not return an "incapable" response if a requesting STA requests the "remote" location.

5) Selects one of possibly several SSPNs advertising support for emergency services and VoIP service.

c) There are two methods described in this annex by which a user lacking security credentials can gain access to the network. The method selected in any particular deployment is at the discretion of the IEEE 802.11 infrastructure provider, SSPN or system administrator as appropriate. The AP and non-AP STA should permit users lacking security credentials to gain access to a network using one of two methods:

1) Using an emergency services association (see 9.4.2.90) in a BSS configured for RSNA. Using this type of association means the AP and non-AP STA exchanges unprotected frames for emergency service access only during the lifetime of the association. In this situation, cryptographic keys are not exchanged, the IEEE 802.1X Uncontrolled Port is bypassed without invoking the IEEE 802.1X state machine. Since protection is used for authenticated STAs, their traffic is protected.

2) Using an SSID configured for Open System authentication. Network elements necessary to complete an emergency call are reachable via this SSID. How to reach these network elements (e.g., a call manager) and which protocol to use (e.g., SIP) are outside the scope of this standard.

d) The AP can separate the backhaul of emergency services traffic from other traffic, typically via a dedicated VLAN.

To ease burden of implementation on the network side, some basic means should exist to allow easy filtering, routing and basic access control of "regular" BSS traffic and emergency-type BSS traffic. This can be assisted by the downloading of emergency call number information, as described in 9.4.5.5.

R.5.4 Description of the Expedited Bandwidth Request element

For access categories configured for mandatory admission control, a non-AP STA requests bandwidth using a TSPEC element in an ADDTS Request frame. The TSPEC Request includes parameters describing the characteristics of the traffic stream, but no information on the use of the traffic stream. The Expedited Bandwidth Request element describes the "use" of a traffic stream. To use this element, it is the responsibility of the station to transmit this element in response to certain call signaling messages. How this is done is outside the scope for the interworking service. The following bandwidth uses are provided in the Expedited Bandwidth Request element:

— Emergency call, defined in NENA 08-002 [B65]
— Public first responder (e.g., fire department)
— Private first responder (e.g., enterprise security guard)
— Multi-level precedence and preemption (MLPP)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

MLPP services are provided by other voice networking technologies such as 3GPP (see 3GPP TS 22.067 [B2]), H.323 (see ITU-T Recommendation H460.14 [B62]) and other proprietary signaling protocols. MLPP is used as a subscription service to provide differentiated levels of consumer service; it is also used by military organizations so that commanding officers will not get a network busy signal.

If the AP is provided additional information regarding the nature of the Traffic Stream, it can invoke additional policy that can be configured on the AP to accept the TSPEC request when it would be otherwise denied. Policy configured at AP defines how bandwidth is allocated. Specification of these policies is outside the scope of interworking with external networks. Policy examples include the following:

— No action
— Preemptive action: delete a TS of lower priority if necessary to make room for new TS
— Use capacity allocated for nonvoice services if priority is above a certain value (assuming TSPEC is for AC_VO)
— Interpret MLPP codes as defined 3GPP specification
— Interpret MLPP codes as defined in proprietary specification

R.5.5 Access to emergency services in an RSN

If an infrastructure BSS requires authentication and encryption with RSN, a non-AP STA placing an emergency call associates and authenticate to the network by using an emergency services association (see 9.4.2.90). If the non-AP STA has user credentials that allow it to use a particular network, the non-AP STA can use its credentials to authenticate to the SSPN through the IEEE 802.11 infrastructure.

When a mesh STA has an emergency services association, and it receives a Mesh Peering Open frame that includes the Interworking element, with ASRA bit equal to 1 and UESA bit equal to 0, and the Authenticated Mesh Peering Exchange element (see 9.4.2.116) it allows access to emergency services. If the mesh STA has user credentials that allow the accessing mesh STA to use the mesh network, the mesh STA can use its credentials to authenticate with the accessing mesh peer.

In order to use an emergency services association in an infrastructure BSS, a STA lacking security credentials can associate with a BSS in which emergency services are accessible by including an Interworking element with the UESA field set to 1 in a (Re)Association Request frame. An AP receiving this type of (re)association request recognizes this as a request for unauthenticated emergency access. The AP can look up the VLAN ID to use with a AAA Server, or it can have an emergency services VLAN configured. The STA can either have, policies configured locally for quality-of-service parameters and network access restrictions, or it can look them up through external policy servers. When a mesh STA has an emergency services association, and it receives a Mesh Peering Open frame, from a mesh STA lacking security credentials, that includes the Interworking element, with ASRA bit equal to 1 and UESA bit equal to 1, and the Mesh Peering Management element (see 9.4.2.100) it allows access to emergency services.

When an emergency services association is used, an infrastructure BSS or an MBSS should be designed to restrict access to emergency services only (or alternatively prioritize the emergency services to the highest level of access). Methods of such restriction are beyond the scope of this standard, but can include an isolated VLAN for emergency services, filtering rules in the AP or network entity (e.g., router) in an external network to limit network access to only network elements involved in emergency calls, and per-session bandwidth control to place an upper limit on resource utilization.

R.6 Peer information

Peer information allows TDLS peer STAs to discover their capabilities. An example of peer information could be expressed in an XML format as follows:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

```
<Peer information>
    <mode> tdls </mode>

    <wireless info>
        <MAC address> 00-01-02-03-04-05 </MAC address>
        <bssid> 00-0a-0b-0c-0d-0e </bssid>
    </wireless info>

    < network info>
        < DHCP> No</DHCP>
        < IP address>192.168.2.1 </IP address>
        < Subnet> 255.255.255.0 </subnet>
        <Hostname> myphone </Hostname>
    </network info>
</Peer information>
```

The minimum required peer information for TDLS is contained in “wireless info.” The “MAC address” field contains the MAC address of the transmitting STA and the “bssid” identifies the BSS in which the STA is a member. The “network info” could optionally be used to aid the peer devices in establishing a TDLS direct link.

R.7 Calculating Estimated Throughput

In response to an MLME-ESTIMATED-THROUGHPUT.request primitive, ESP STAs can determine values for EstimatedThroughputInbound and EstimatedThroughputOutbound for each AC of a current or potential link to another STA using Equation (17):

$$EstimatedThroughput = \frac{EST_{AirtimeFractionDir} \times MPDU_{pPPDU} \times A\_MSDU\_B \times 8}{(CWmin/2 + AIFSN[AC]) \times aSlotTime + 2 \times SIFS + BA\_PPDU_{Dur} + PPDU_{Dur} + OtherOverhead_{Dur}} \quad (17)$$

where

EstimatedThroughputis in b/s and is calculated separately for inbound and outbound transmissions for this link

$PPDU_{Dur}$is the expected duration of a single PPDU, in seconds

$EST_{AirtimeFractionDir}$is dimensionless. It is the estimated portion of air time that is available for inbound or outbound transmissions for this link when calculating EstimatedThroughput for inbound and outbound directions, respectively. The value of this parameter is based on the value of the Estimated Inbound Air Time Fraction or Estimated Outbound Air Time Fraction subfield, respectively, of the Estimated Service Parameters Inbound element or Estimated Service Parameters Outbound element, respectively, received from the STA with the MAC address that matches the PeerSTAAddress in the MLME-ESTIMATED-THROUGHPUT.request primitive, using a method that is beyond the scope of this standard

AIFSN[AC]is calculated according to 10.23.2.4 where the AC value corresponds to the AC of the Data frames

$BA_PPDU_{Dur}$is the expected duration of a PPDU containing a BA using the rate indicated for a BA response to an MPDU using the rate of DataRate as determined according to 10.6.6

$OtherOverhead_{Dur}$is in seconds. It is a term that includes airtime that is needed for additional overhead per Data PPDU, which is not already account for in the existing terms in the denom-

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

inator of Equation (17), such as an optionally present RTS/CTS exchange and its accompanying, appropriate interframe space and collision and PER losses

min(x,y) is the minimum of x and y

max(x,y)is the maximum of x and y

$MPDU_{pPPDU}$ = min(BA_WIN_Size, max(1,MPDU_pA_MPDU))

BA_WIN_Size = min($BA\_WIN\_Size_{TX}$,$BA\_WIN\_Size_{RX}$)

$BA_WIN_Size_{TX}$is the expected block ack window size of the transmitter of the PPDUs containing MPDUs with the Type field equal to Data

$BA_WIN_Size_{RX}$is the expected block ack window size of the receiver of the PPDUs containing MPDUs with the Type field equal to Data

MPDU_pA_MPDUis dimensionless, and is calculated as shown in Equation (R-1)

$$MPDU\_pA\_MPDU = \min\left(\left\lfloor \frac{PPDUR}{MPDU_{SS}} \right\rfloor, \left\lfloor \frac{PPDUR \times DataRate}{(MAC_{Hdr} + A\_MSDU\_B + 4 + (4 - (MAC_{Hdr} + A\_MSDU\_B) \bmod 4)) \times 8} \right\rfloor\right) \quad \text{(R-1)}$$

PPDUR = DPDUR – PHDUR

PPDURis the PPDU payload duration, in seconds

DPDUR is the Data PPDU duration target of the transmitter of the PPDUs containing MPDUs with the Type subfield equal to Data, in seconds. For calculations of inbound Estimated Throughput, the value of this variable is equal to the time indicated in the Data PPDU Duration Target subfield of the Estimated Service Parameters Inbound element (see 9.4.2.172). For calculations of outbound Estimated Throughput, the value of this variable is determined by the STA performing the calculation using a method that is beyond the scope of this standard. A value of 5430 μs is recommended for such calculations

PHDURis the PHY header duration, estimated based on the expected PPDU format of the PPDUs containing MPDUs with the Type subfield equal to Data, in seconds

$MPDU_{SS}$ is the minimum MPDU start spacing of the receiver of the PPDUs containing MPDUs with the Type subfield equal to Data, in seconds

$MAC_{Hdr}$is the number of octets of MAC header information for an A-MSDU

A_MSDU_B = min($A\_MSDU\_B_{TX}$, $A\_MSDU\_B_{RX}$)

$A\_MSDU\_B_{TX}$ is a number of octets which is equal to the maximum A-MSDU size of the transmitter of the PPDUs containing MPDUs with the Type subfield equal to Data if the MPDUs are expected to contain A-MSDUs. If the MPDUs are not expected to contain A-MSDUs, then the value is a number of octets equal to the AverageMSDUSizeInbound or AverageMSDUSizeOutbound, respectively, depending on whether the EstimatedThroughput being calculated is inbound or outbound

$A\_MSDU\_B_{RX}$ is a number of octets which is equal to the maximum A-MSDU size of the receiver of the PPDUs containing MPDUs with the Type subfield equal to Data if the MPDUs are expected to contain A-MSDUs. If the MPDUs are not expected to contain A-MSDUs, then the value is a number of octets equal to the AverageMSDUSizeInbound or AverageMSDUSizeOutbound, respectively, depending on whether the EstimatedThroughput being calculated is inbound or outbound

$$PPDU_{Dur} = \left\lceil \frac{(MAC_{Hdr} + A\_MSDU\_B) \times MPDU_{pPPDU} \times 8}{DataRate \times DSYM_{DUR}} \right\rceil \times DSYM_{DUR} + PHDUR \quad \text{(R-2)}$$

$DSYM_{DUR}$is the duration of one PPDU payload symbol for the expected PHY format of the PPDUs containing MPDUs with the Type subfield equal to Data, in seconds. If multiple symbol durations are possible, then the shortest symbol duration is assumed

DataRate is calculated using equation Equation (R-3), in b/s

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

$$DataRate = \min(\log2(1 + SNR\_tone), MaxBitsPerSc) \times \frac{NSS\_max \times Ntone}{DSYM_{DUR}} \quad \text{(R-3)}$$

where

$$SNR\_tone = 10^{\frac{RSSI + P_{adjust}}{10}}$$

RSSI is the RSSI of Beacon or Probe Response frames received from the STA with the MAC address that matches the PeerSTAAddress in the MLME-ESTIMATED-THROUGHPUT.request primitive, in dBm

P_adjustis the implementation specific power adjustment parameter used to convert RSSI into SNR, as well as take into account potential transmit power differences between Beacon/ Probe Response frames to Data frames and between STAs for which the estimation is being performed, in dBm

NSS_maxis the maximum number of spatial streams allowed in the link based on the capabilities of the two STAs

Ntone is N_SD × N_Seg if the expected PPDU format is VHT, and N_SD otherwise, where N_SD is defined as number of subcarriers in Table 17-19 for non-HT format, NSD in Table 19-6 for HT format and NSD in Table 21-5 for VHT format. If multiple channel bandwidths are available, the N_SD of the widest possible TXVECTOR CH_BANDWIDTH allowed between the two STAs based on capabilities is assumed.

$$MaxBitsPerSc = \begin{cases} \frac{40}{6}, \text{ if 256-QAM 5/6 modulation is allowed in the link} \\ 6, \text{ if 256-QAM 3/4 modulation is allowed in the link} \\ \quad \text{but 256-QAM 5/6 modulation is not} \\ 5, \text{ otherwise} \end{cases}$$

NOTE 1—The equations above do not account for signal extension.

NOTE 2 —The STA can adjust the value of $EST_{AirtimeFractiondir}$ based on knowledge about whether it is currently competing for airtime with the targeted BSS and would no longer do so if the STA joins that BSS.

Annex S

(informative)

Mesh BSS operation

S.1 Clarification of mesh Data frame format

A mesh Data frame consists of MAC header, frame body, and the FCS. The fields in the MAC header are described in 9.2.3.

In a mesh Data frame containing a single MSDU, the Mesh Control field is placed immediately before the Data (PDU) in the encrypted portion of the frame body. The Data (PDU) comprises the LLC/SNAP headers and the higher layer data. This is shown in the example frame format for a CCMP-128-encrypted mesh Data frame containing a single MSDU in Figure S-1.

When the mesh Data frame is fragmented, only the first fragment contains the Mesh Control field.

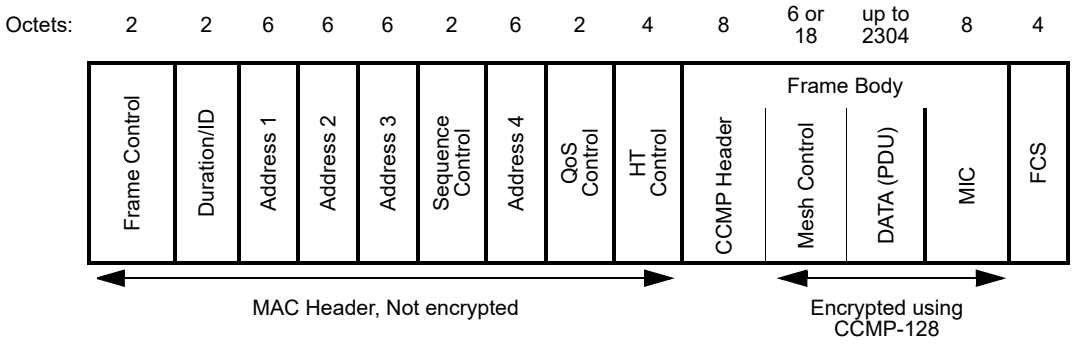

Figure S-1—Format of a CCMP-128-encrypted mesh Data frame containing a single MSDU

NOTE—A DMG STA does not send mesh Data frames, and all other STAs have a maximum MSDU size of 2304 octets (see Table 9-34).

S.2 Operational considerations for interworking

No special action is required to support formation of the IEEE 802.1Q spanning tree. Spanning tree control messages are typically delivered to bridges in group addressed frames. These messages are Data frames from the point of view of the mesh BSS.

S.3 Power save parameters selection

S.3.1 General

Power save mechanisms enable mesh STA operation in doze state. In doze state a mesh STA might set the transceivers off. The power save mechanism might adjust the mesh power management mode of a mesh

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

STA for various reasons that are beyond the scope of the standard, including but not limited to traffic load or scanning and network maintenance needs.

This annex specifies recommendations on how a mesh STA selects mesh power management modes based on traffic load, recommendations on how to do scanning in mesh BSSs that might contain mesh STAs in light or deep sleep mode, and recommended default values for power save related parameters.

S.3.2 Selecting the mesh power management mode based on traffic load

A mesh STA might adjust its mesh power management mode based on the traffic load or the QoS requirements of the forwarded traffic. If a mesh STA has high traffic load or if a mesh STA is congested, the mesh STA should operate in active mode on the corresponding mesh peering to reduce delays or overhead that might be created by the operation in light or deep sleep mode.

A mesh STA might consider staying in active mode for all peer mesh STAs, even if only a single link is congested. When mesh STA operates in active mode, the mesh STA might receive frames at any time and mesh peer service periods might be triggered on demand, as in case of an AP that receives a trigger frame at times controlled by a non-AP STA.

If traffic load is moderate or low and best effort data is transmitted, a mesh STA might consider staying in light sleep mode for all or some mesh peerings. The mesh STA in light sleep mode for a mesh peering receives beacons from the peer mesh STA with periodic indication of buffered traffic.

If traffic load is low or no traffic is transmitted, a mesh STA might consider staying in deep sleep mode for a mesh peering. The mesh STA does not need to transition to awake state to receive a beacon from the peer mesh STA to which it is in deep sleep mode.

The mesh STA might use deep sleep mode to control the number of times it enters the awake state to receive Beacon frame from a peer mesh STA. If the mesh STA is in deep sleep mode for all of its mesh peering, the mesh STA needs only to remain in awake state during its own beacon transmission and mesh awake window.

The mesh STA that forwards real time traffic (AC3 or AC2 with EDCA) should be in active mode for the corresponding link. A mesh STA forwarding real time traffic with EDCA might stay in light or deep sleep mode for the corresponding link, if the mesh STA is capable of initiating mesh peer service periods frequently and the other forwarding peer mesh STAs are in active mode. Poor handling of the mesh power management modes might result to delays and inappropriate QoS of the forwarded MSDUs.

S.3.3 Scanning of mesh BSSs

A mesh BSS might have mesh STAs that alternate awake state and doze state. With active scanning only devices in awake state at the transmission time of Probe Request frame might be found. However, with passive scanning also mesh STAs in light or deep sleep mode for a mesh peering can be found.

Since mesh STAs in light or deep sleep mode might transmit beacons at long intervals, a mesh STA seeking for candidate mesh STAs for a new mesh peerings should perform passive scanning relatively for a longer time compared to passive scanning in BSS infrastructure mode. Mesh STAs in light or deep sleep mode with long DTIM interval might not be discovered with short scanning durations. Mesh STAs that operate in light or deep sleep mode for a mesh peering might use a short DTIM interval, if they intend to establish new mesh peerings.

S.3.4 Default parameters

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

Table S-1 shows the recommended default values for power save related parameters for mesh STAs.

Table S-1—Default parameters for mesh STAs that intend to operate in light or deep sleep mode for mesh peerings

	For moderate power save	For aggressive power save
Beacon period	200 TU	800 TU
DTIM Period	4	1
Mesh awake window	10 TU	10 TU

A mesh STA that is eager to conserve power and likely to remain in deep sleep mode with most of the mesh peerings should utilize the value from aggressive power save parameters.

Although mesh STAs might utilize individual parameters regardless of the parameters used by neighbor mesh STAs or peer mesh STAs, each implementer should recognize balance between the power save efficiency and delay in the service initiation.

S.3.5 MSDU forwarding in an MBSS containing mesh STAs in light or deep sleep mode

The battery powered mesh STAs should avoid forwarding MSDUs, to avoid power consumption and possible additional delays and inefficiencies that power save mechanisms might cause. If a light or deep sleep mode mesh STA forwards MSDUs, it should select its mesh power management mode based on the traffic load and the traffic type as described in S.3.2.

A mesh STA might save power by selecting the light or deep sleep mode for a mesh peering as follows:

— A mesh STA that is “mains powered” might apply light or deep sleep mode if it does not have MSDUs to forward

— A mesh STA that is “battery powered” might freely use all mesh power management modes

Mesh STAs that are in light or deep sleep mode for a mesh peering might degrade the corresponding link metric value. The use of worse metric values reduces the probability of a link being used for MSDU forwarding. If the mesh STA will operate in active mode for the link in forwarding path, it should apply the link metric value without degradation.

S.3.6 Synchronization maintenance of mesh STAs in deep sleep mode

A mesh STA in deep sleep mode for a mesh peering might not receive Beacon frames from the corresponding peer mesh STA, but the mesh STA is required to maintain synchronization with the neighbor peer mesh STAs. Neighbor offset synchronization method imposes the maintenance of TSF offset values between neighbor peer mesh STAs, which generally requires the reception of Beacon frame or Probe Response frame. The simplest way to maintain the synchronization is that the mesh STA in deep sleep mode for a mesh peering listens to the corresponding peer mesh STA’s Beacon frame for certain periods and check the TSF offset value.

S.5 Airtime link metric usage example

The airtime cost constants (Table 14-4) and estimates of the average data rate and frame error rate will vary from one implementation and configuration of the IEEE 802.11 PHY and MAC to the other. While no mechanism is defined to measure the average data rate and the frame error rate, numeric values are not expected to exhibit large variations in amplitude over the lifetime of a path. Unstable measurements might cause path selection instabilities.

An example of an airtime link metric is provided to illustrate how it might be calculated.

Assume a DSSS PHY with an average data rate of 1 Mb/s to a given neighbor and a frame size of 8192 bits.

The overhead O for the Data frame comprises the PHY preamble (144 μs) and the PHY header (48 μs). The payload Bit is 8192 bits at an r of 1 Mb/s, or 8192 μs. The data transmission time is therefore 8416 μs. Other transmission times for different frame types are calculated in the same way (based on their size, rate, and overhead).

If RTS/CTS is used, the data transmission time (including PHY preamble and header) is 8416 μs, the RTS transmission time (including PHY preamble and header) is 352 μs, the CTS frame transmission time (including PHY preamble and header) is 304 μs, the Ack frame transmission time (including PHY preamble and header) is 304 μs and the interframe spacing overhead is 390 μs. The total time, including overhead, is 9766 μs.

This airtime and overhead value is converted to units of 0.01 TU (10.24 μs), i.e., 953.71 (rounded to 954).

If the frame error rate to the neighbor is 0%, the metric is 954. If the frame error rate is 80%, the metric is 4769 [i.e., Round(953.71/(1–0.8))].

S.6 Link metric report example

When HWMP is activated as the active path selection protocol in a mesh BSS, the link metric of a link is determined by a STA that received a PREQ frame or RANN frame over the link. To establish a reliable mesh path, it is desirable that the link metric value is calculated considering the bidirectional link quality, particularly because HWMP generates a single mesh path for bidirectional transmissions. Link metric reporting is used to collect a link metric value calculated by the peer STA, so that STA can determine the bidirectional quality of a link.

The following procedure explains one example practice of link metric calculation using link metric reporting, when HWMP is activated.

a) The STA monitors the MCS of Data frames transmitted to a peer STA and calculates the averaged metric value M_{TX} of the link toward the peer STA. The STA updates M_{TX} when it transmits a Data frame to the peer STA. If the STA has not transmitted Data frames to the peer STA recently, M_{TX} might be approximated from the strength of the signal (RSSI) received from the peer STA.

NOTE—The mechanism by which the RSSI is obtained is outside the scope of this standard.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

b) The STA transmits Mesh Link Metric Report frames containing the metric value M_{TX} to the peer STA.

c) When the STA receives a Mesh Link Metric Report frame from the peer STA, it stores the reported metric value as M_{RX} of the link. If the STA has not received a Mesh Link Metric Report frame recently, the STA might invalidate M_{RX}.

d) When the STA is in need of the link metric value of the link, i.e., it received an HWMP Mesh Path Selection frame to determine an active mesh path, it calculates the link metric for the path selection M_{PATH} using the following equation:

$$M_{PATH} = \alpha \times M_{TX} + (1 - \alpha) \times M_{RX}$$

where α is the ratio of the outgoing traffic on the link versus total traffic on the link. If this ratio is unknown, it is set to 0.5. If M_{RX} is invalidated, it is set to 1.0.

S.7 Generation of proactive PREP elements in the proactive PREQ mechanism of HWMP

S.7.1 General

In the proactive PREQ mechanism of HWMP, the generation of a proactive PREP element in response to a proactive PREQ element depends on the value of the Proactive PREP subfield in the received proactive PREQ element (see 14.11.4.2). Furthermore, if the Proactive PREP subfield is 0, the mesh STA might respond with the proactive PREP element in case it needs a bidirectional path between the root mesh STA and itself. This is usually the case if the mesh STA has data to be sent to the root mesh STA. This clause provides a unified mechanism that controls the generation of proactive PREP elements in the proactive PREQ mechanism of HWMP.

A proactive PREQ element is defined by all of the following:

— The Target Address is set to all 1s, and

— The TO subfield in the Per Target Flags field is 1.

S.7.2 Additions to forwarding information

The forwarding information to a root mesh STA contains two additional Boolean information fields. The Proactive PREP field indicates whether the mesh STA will generate a proactive PREP element to the root mesh STA in response to a proactive PREQ element (Proactive PREP = 1) or not (Proactive PREP = 0). The Proactive PREP Sent field indicates whether the mesh STA has sent a proactive PREP element to the root mesh STA (Proactive PREP Sent = 1) or not (Proactive PREP Sent = 0). Both fields are initialized with 0.

S.7.3 Actions when sending Data frames as source mesh STA

If a mesh STA receives proactive PREQ elements with the Proactive PREP subfield set to 0, the recipient mesh STA sends a proactive PREP element before sending a Data frame as source mesh STA only if the mesh STA has data to send to the root mesh STA, which requires establishing a bidirectional path with the root mesh STA and the field Proactive PREP Sent of the forwarding information to the root mesh STA is not set (=0).

If the mesh STA sends a Data frame as source mesh STA to the root mesh STA, the mesh STA sets the field Proactive PREP of the forwarding information to 1.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

S.7.4 Actions on receipt of a proactive PREQ element

If the mesh STA receives a proactive PREQ element, the field Proactive PREP Sent of the forwarding information to the root mesh STA is set to 0. If the field Proactive PREP of the forwarding information to the root mesh STA is 1, the mesh STA generates a proactive PREP element to the root mesh STA (see 14.11.10.3 Case D), sets the field Proactive PREP of the forwarding information to 0, and sets the field Proactive PREP Sent of the forwarding information to 1.

If the Proactive PREP subfield of the Flags field of the received proactive PREQ element is 1, the mesh STA sets the field Proactive PREP of the forwarding information to the root mesh STA to 1.

S.7.5 Generation of proactive PREP elements

A mesh STA will generate a proactive PREP element according to 14.11.10.3 Case D if one of the following applies:

— [The mesh STA has received a proactive PREQ element] AND [in the forwarding information to the root mesh STA of the proactive PREQ element, field Proactive PREP is set to 1 AND field Proactive PREP Sent is set to 0].

— [The mesh STA has data to send to the root mesh STA, which requires establishing a bidirectional path with the root mesh STA] AND [the field Proactive PREP Sent of the forwarding information to the root mesh STA is not set (=0)].

If the mesh STA generates a proactive PREP to the root mesh STA, the field Proactive PREP Sent of the forwarding information is set to 1 and the field Proactive PREP of the forwarding information is set to 0.

S.8 Generation of PREQ elements in proactive RANN mechanism of HWMP

S.8.1 General

In the proactive RANN mechanism of HWMP, the generation of a PREQ element for root path confirmation in response to a RANN element depends on the path metric from the mesh STA to the root mesh STA as computed by the RANN element propagation. However, the RANN mechanism does not set up the necessary forwarding information. This is done with individually addressed PREQ elements. This clause provides further details to the generation of individually addressed PREQ elements in the proactive RANN mechanism of HWMP.

An individually addressed PREQ element is defined by the following:

— The Addressing Mode subfield in the Flags field is 1 (individually addressed).

S.8.2 Additions to forwarding information

The forwarding information to a root mesh STA contains an additional address field. The RANN element Sender Address field contains the MAC address of the neighbor peer mesh STA that has sent the RANN element with the best metric.

S.8.3 Actions when sending Data frames as source mesh STA

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If the mesh STA sends a Data frame as source mesh STA to the root mesh STA, the mesh STA uses the forwarding information to the root mesh STA. The RANN element Sender Address is not used for forwarding mesh Data frames to the root mesh STA.

S.8.4 Actions on receipt of proactive RANN element

If the mesh STA receives a proactive RANN element, the field RANN element Sender Address of the forwarding information to the root mesh STA is set to the sender of the RANN element if the metric to the root mesh STA is better than the path metric of the existing mesh path in the forwarding information.

In this case, the mesh STA generates an individually addressed PREQ element to the root mesh STA; see 14.11.10.3 Case D. This individually addressed PREQ element is not sent according to the general forwarding information. Instead, it is sent to the neighbor peer mesh STA indicated in the RANN element Sender Address field.

Since all mesh STAs between the mesh STA and the root mesh STA have already a value in the RANN element Sender Address field, the individually address PREQ element will eventually reach the root mesh STA. Since the TO subfield in the Per Target Flags field is 1, only the root mesh STA will generate a PREQ element as reply to the individually addressed PREQ element.

The individually addressed PREQ elements will set up forwarding information (that can be used for forwarding mesh Data frames) from the root mesh STA toward the mesh STA that initiated the root path confirmation in all intermediate mesh STAs according to the normal HWMP procedures.

Note, since the PREQ element is sent in an individually addressed frame, every sender of the individually addressed PREQ element will be able to determine whether the next mesh STA toward the root mesh STA has received the PREQ element.

The root mesh STA will generate a PREP element according to the normal HWMP procedures; see 14.11.10.3 Case A.

S.8.5 Actions on receipt of a PREP element

The PREP element generated by the root mesh STA will be forwarded on the mesh path from the root mesh STA to the mesh STA as set up by the individually addressed PREQ element. The PREP element will be propagated and will eventually reach the mesh STA. The PREP element will set up forwarding information (that can be used for forwarding mesh Data frames) toward the root mesh STA in the mesh STA that initiated the root path confirmation and in all intermediate mesh STAs on this path according to the normal HWMP procedures.

After establishing the forwarding information (mesh path) toward the root mesh STA, the path to the root mesh STA is updated to the better one.

Note that since the PREP element is sent in an individually addressed frame, every sender of the PREP element will be able to determine whether the next mesh STA has received the PREP element.

Annex T

(informative)

Overlapping BSS (OBSS) management

T.1 Introduction

When two or more BSSs overlap, the available bandwidth is shared and hence reduced for each BSS. The basic access mechanism, such as DCF, is able to work across OBSSs. Similarly, if EDCA is used, the OBSS might be considered a larger network, and access to the WM is basically shared according to the EDCA access mechanism. Note that for both DCF and EDCA overlapping networks, the sharing is affected by the relative traffic; and if more than two APs are sharing, the problem of "neighbor capture" might occur. The neighbor capture effect might occur when a BSS is in the middle of two other BSSs that are hidden from each other, where it might suffer a disproportionate degradation in throughput, relative to the total traffic in all three BSSs. A particular problem arises when there is some expectation of QoS. If EDCA admission control is in use, then it can be used to regulate the QoS traffic on its own BSS, but it might not take into account the EDCA admitted traffic on an OBSS. The result is that the QoS is compromised if each BSS admits traffic up to its local maximum. Similarly a BSS using HCCA might schedule traffic in its own BSS, to "guarantee" a service, but, if not controlled, this might suppress overlapping EDCA admission control BSS. Furthermore, if two HCCA BSSs overlap and they do not coordinate their scheduled TXOPs, then a degradation of QoS might result. An HE BSS advertises BSS color information, which is a value in the range 1 to 63 that identifies the BSS. Based on the BSS color information, a receiving STA can make decisions on whether to access the medium while there is ongoing transmission on the medium or go to doze state until the end of the received PPDU or update the NAV. The features described in this annex have been introduced in order to allow a degree of management for OBSSs and for mitigation of the basic problems outlined above.

T.2 QLoad Report element

T.2.1 General

The fields and their uses in the QLoad Report element are as follows:

— Potential Traffic Self field value represents the potential QoS traffic load that this AP is expecting and is provided as an indication to other APs that might be considering selecting the same channel and for sharing when an OBSS situation occurs. The Potential Traffic Self field also includes the peak number of AC_VO and AC_VI EDCA streams.

— Allocated Traffic Self field value represents the total QoS traffic and the numbers of AC_VI and AC_VO streams that are active at that time. This field is provided to enable an on-demand sharing scheme. It might be used by the other APs in OBSSs to determine if the AP has either overallocated in a proportional sharing scheme or is using an on-demand sharing scheme.

— Allocated Traffic Shared field contains the sum of the Allocated Traffic Self field values for OBSSs and is used to protect an AP from the neighbor capture effect where an AP that has neighbors that are hidden from each other. It indicates to other APs in OBSSs if this AP has either overallocated in a proportional sharing scheme, or might be using an on-demand sharing scheme.

— EDCA Access Factor field value represents the total QoS traffic bandwidth requirement for all of the APs in OBSSs and is used to indicate potential overallocation. It also enables a proportional sharing scheme. The Potential Traffic Self fields from QLoad Report elements of nearby co-channel

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

APs are used for estimating the overhead bandwidth required due to EDCA contention and is used in the determination of the EDCA Access Factor.

— HCCA Peak field value represents the total peak HCCA TXOP requirement for the BSS and is provided so that other overlapping APs can determine whether the AP has overallocated.

— HCCA Access Factor field contains the sum of all of the HCCA Peak field values in all of the QLoad Reports of all of the overlapping APs, including its own. This value is used when HCCA APs are sharing as defined in 11.26.2.

— Overlap field value is the number of other APs that are on the same channel and from which Beacon frames are being regularly received. It might be used to aid the channel selection process.

T.2.2 Calculating medium time

This annex uses the function defined in Equation (T-1) for calculating and estimating medium times in both ACM and non-ACM QoS modes:

$$\text{mediumTime}(s,d,m,p) = s \times pps \times MPDUExchangeTime \quad \text{(T-1)}$$

where

$$pps = \left\lceil \frac{d}{8 \times m} \right\rceil \quad (21)$$

$$MPDUExchangeTime = \text{duration}(m,p) + SIFS + \text{duration}(14,p) \quad (22)$$

duration() is the PLME-TXTIME primitive that returns the duration of a frame based on its payload size and the PHY data rate employed.

s, d, m and p are parameters that are passed in to the mediumTime function

(Also see the definition of MPDUExchangeTime in 10.23.4.2.3.)

T.2.3 Calculation of potential traffic self

The Potential Traffic Self field value represents the sum of all of the streams derived from all of the potential EDCA admission control and HCCA QoS traffic. The individual TSPEC elements provided by the non-AP STAs are used by the AP to calculate mean, maximum, and minimum values for

— Medium time, in units of 32 μs/s, in the case of EDCA admission control

— HCCA medium time, in the case of HCCA; where HCCA medium time is the TXOP time scheduled by the HC converted to units of 32 μs/s, by dividing the scheduled TXOP time by the SI that the HC has allocated

The AP maintains a <mean, standard deviation, AC_VO, AC_VI> tuple that contains the maximum values from Allocated Traffic Self field. The values of this tuple are calculated using

a) The mean and standard deviation from the Allocated Traffic Self field that had the largest value of the Mean subfield

b) The AC_VO Streams subfield from the Allocated Traffic Self field that had the largest value

c) The AC_VI Streams subfield from the Allocated Traffic Self field that had the largest value

This <mean, standard deviation, AC_VO, AC_VI> tuple is calculated over fixed, consecutive seven-day periods and is reset at the start of each new period. If, at any time, any of the maximum values in the tuple are greater than those in the corresponding subfields of the Potential Traffic Self field, then those fields in the Potential Traffic Self field are set to the value(s) in the tuple. If the AP refuses an ADDTS request due to

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

a perceived overallocation (for example, step b) 4) in the proportional sharing scheme described in T.4.2.2), then the AP adds the TSPEC values of the rejected request to the tuple.

At the end of each seven-day period, if any of the maximum values in the tuple are less than those in the corresponding subfields of the Potential Traffic Self field, then those subfields in the Potential Traffic Self fields are set to the value(s) in the tuple.

NOTE—It is not required that the start and end of the seven-day periods be synchronized across OBSSs. After the first seven-day period, each AP advertises its correct potential load irrespective of its start time.

TSPECs provide for mean, maximum, and minimum bit rate values, which allow for statistical multiplexing of streams. The result of summing multiple streams is a composite stream, which should be reported in the Potential Traffic Self field. The summing of streams to produce a composite stream is achieved by using the mean and standard deviation of each stream.

The mean (MEAN), maximum (MAX), and minimum (MIN) values of the medium time or HCCA medium time should be calculated using the values provided in the individual TSPECs, as follows:

For a TSPEC for stream, *i*, is:

$$MIN_i = \text{mediumTime}(\textit{Surplus Bandwidth Allowance, Nominal MSDU Size, Minimum Data Rate, Minimum PHY Rate}) \quad (23)$$

$$MEAN_i = \text{mediumTime}(\textit{Surplus Bandwidth Allowance, Nominal MSDU Size, Mean Data Rate, Minimum PHY Rate}) \quad (24)$$

$$MAX_i = \text{mediumTime}(\textit{Surplus Bandwidth Allowance, Nominal MSDU Size, Peak Data Rate, Minimum PHY Rate}) \quad (25)$$

$$\mu_i = MEAN_i \quad (26)$$

If the Minimum Data Rate and Peak Data Rate fields were provided in the TSPEC element, σ is:

$$\sigma_i = 0.25(MAX_i - MIN_i) \quad (27)$$

Else if the Peak Data Rate field was provided in the TSPEC element, σ is:

$$\sigma_i = \frac{MAX_i - MEAN_i}{2} \quad (28)$$

Otherwise:

$$\sigma_i = 0 \quad (29)$$

When the non-AP STA does not have any active TSPECs, the AP should monitor the mean and maximum frame reception and transmission rates for AC_VI and AC_VO (for example, by regular sampling of changes to dot11QosMPDUsReceivedCount and dot11QosTransmittedFrameCount of each AC) to calculate the potential load information as follows:

For a QoS traffic capability, the mean value, μ, is:

$$\mu_0 = \text{mediumTime}(\text{dot11DefaultSurplusBandwidthAllowance}/100, \text{dot11STAStatisticsAverageMSDUSizeVideo}, \textit{MAXt[VI]}, \text{dot11STAStatisticsAverageBitrateVideo}) \quad (30)$$

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

μ_1 = mediumTime(dot11DefaultSurplusBandwidthAllowance/100,
dot11STAStatisticsAverageMSDUSizeVoice,
MAXt[VO],
dot11STAStatisticsAverageBitrateVoice) (31)

and the standard deviation, σ, is:

$$\sigma_0 = 0 \quad (32)$$

$$\sigma_1 = 0 \quad (33)$$

The values reported in the Potential Traffic Self field represent the composite stream of all of the individual streams of all associated STAs, and this composite stream should be calculated as follows:

Potential traffic self mean is:

$$\mu_{tot} = \Sigma\mu_i \quad (34)$$

Potential traffic self standard deviation:

$$\sigma_{tot} = \sqrt{\sum \sigma_i^2} \quad (35)$$

T.2.4 Calculation of allocated traffic self

The Allocated Traffic Self field value represents the total BSS load of all streams that the AP has allocated at any one time and the number of AC_VI and AC_VO streams that make up that total. The AP should calculate the mean and standard deviation using the Minimum Data Rate, Mean Data Rate, and Peak Data Rate fields of admitted TSPECs and to recalculate the Allocated Traffic Self field value as each TS is added or deleted. The values of the Mean and Standard Deviation subfields placed in the Allocated Traffic Self field for *i* allocated streams should be calculated using Equation (36) to Equation (43).

MIN_i = mediumTime(*Surplus Bandwidth Allowance, Nominal MSDU Size, Minimum Data Rate, Minimum PHY Rate*) (36)

$MEAN_i$ = mediumTime(*Surplus Bandwidth Allowance, Nominal MSDU Size, Mean Data Rate, Minimum PHY Rate*) (37)

MAX_i = mediumTime(Surplus Bandwidth Allowance, Nominal MSDU Size, *Peak Data Rate, Minimum PHY Rate*) (38)

If $TSPEC_i$ has the Minimum Data Rate and Peak Data Rate fields populated, σ is:

$$\sigma_i = 0.25(MAX_i - MIN_i) \quad (39)$$

Else if $TSPEC_i$ has the Mean Data Rate and Peak Data Rate fields populated, σ is:

$$\sigma_i = \frac{MAX_i - MEAN_i}{2} \quad (40)$$

Otherwise:

$$\sigma_i = 0 \quad (41)$$

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

$$\text{Mean} = \Sigma\mu_i \tag{42}$$

$$\text{Standard deviation} = \sqrt{\sum \sigma_i^2} \tag{43}$$

When admission control is not used, the AP should monitor the mean and maximum frame reception and transmission rates for AC_VI and AC_VO (for example, by regular sampling of changes to dot11QosMPDUsReceivedCount and dot11QosTransmittedFrameCount of each AC). The MAX, MEAN, and standard deviation (STDEV) at time t for access category AC are as given in Equation (44), Equation (45), and Equation (46).

$$MEAN_i = o\ (\text{duration}(s, b) + \text{SIFS} + \text{duration}(14,b))\ p_t \tag{44}$$

MAX_t is the maximum value of $MEAN_t$ since MLME-START.confirm

$$STDEV_t = \frac{MAX_t - MEAN_t}{2} \tag{45}$$

where

$$p_t = \frac{d}{dt}(dot11QosMPDUsReceivedCount[AC] + dot11QosTransmittedFrameCount[AC] - dot11QosFrameDuplicateCount[AC]) \tag{46}$$

o = dot11DefaultSurplusBandwidthAllowance

s = dot11STAStatisticsAverageMSDUSizeVideo

b = dot11STAStatisticsAverageBitrateVideo

duration() is the PLME-TXTIME primitive that returns the duration of a packet based on its payload size and the PHY data rate employed

NOTE—The differentiation above calculates the frames per second for the given AC.

T.2.5 Calculation of allocated traffic shared

The Allocated Traffic Shared field value is the sum of the values expressed in the Allocated Traffic Self fields of all APs in OBSSs, including in its own Allocated Traffic Self field. The values of the mean μ and standard deviation σ, placed in the Allocated Traffic Shared field, for n OBSSs should be calculated using Equation (47) and Equation (48).

$$\mu = \Sigma\mu_n \tag{47}$$

$$\sigma = \sqrt{\sum \sigma_n^2} \tag{48}$$

T.2.6 Calculation of EDCA Access Factor

The EDCA Access Factor is the total traffic requirement for all of the OBSSs. The value of EDCA Access Factor might be greater than 1. The EDCA Access Factor should be calculated from the addition of all of the Potential Traffic Self fields of the APs that are overlapping as follows:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

First calculate the overlap traffic for all of the APs in OBSSs. Each AP notes the reported Potential Traffic Self fields for every OBSS, including the AP's own Potential Traffic Self field, and calculates the maximum traffic of the composite stream, using Equation (49), Equation (50), and Equation (51).

$$\text{Overlap traffic} = \mu_{tot} + 2\,\sigma_{tot} \tag{49}$$

where, for i Potential Traffic Self fields

$$\mu_{tot} = \Sigma\mu_i \tag{50}$$

$$\sigma_{tot} = \sqrt{\sum \sigma_i^{\,2}} \tag{51}$$

This overlap traffic value is in units of 32 μs/s.

The following procedure should be used to calculate the EDCA Access Factor:

a) Sum the AC_VI and AC_VO priority streams reported in the Potential Traffic Self fields of its own QLoad report and all of the QLoad reports of APs in OBSSs, and determine the EDCA Overhead Factor as recommended in T.2.7.

b) Multiply the overlap traffic and the resulting EDCA Overhead Factor together. This value represents the total overlap traffic requirement for the OBSSs in units of 32 μs/s.

c) Convert the total overlap traffic to a fraction (seconds per second) by multiplying by 32×10^{-6}.

d) Round the resulting fraction value rounded down to a multiple of 1/64.

For example, if the total overlap traffic is 74 268 (32 μs/s), this is 2.376 576 (seconds/second). Now 2.376 576 × 64 = 152.1 rounded to 152. Hence, the EDCA Access Factor octet, in this case, would be 1001100 (152 in decimal, representing the fraction 152/64).

T.2.7 EDCA Overhead Factor

The Potential Traffic Self field also includes the number of AC_VI and AC_VO streams that make up the composite stream. The recommended calculation for medium time for an admitted EDCA is given in K.2.2. This value includes the duration of the packet plus SIFS and Ack frame times. The medium time, therefore, does not include the access time. For example, for a single stream, between each transmitted packet, there is a time period due to SIFS, AIFSN, and contention window, and for two or more streams, there is also the time when each packet is delayed while another packet is being transmitted. Hence, in order to calculate the total time or bandwidth required to service multiple EDCA streams, an overhead is present.

A fixed value of 1.34 should be used for EDCA Overhead Factor. The value of the EDCA Overhead Factor is dependent upon many factors, including

— Number and mix of streams, voice and video
— Mixture of PHY rates and PHYs
— Mixture of streams' data rates
— Use and mix of aggregated MSDUs
— Choice of EDCA parameters including different settings in OBSSs

Based on a range of simulations, the value of EDCA Overhead Factor is normally in the range 1.26 to 1.43. These simulations, however, were not exhaustive and did not include the effects of hidden nodes and non-IEEE 802.11 interference.

T.2.8 Calculation of HCCA Access Factor

The HCCA Access Factor should be calculated as follows:

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

a) Sum the HCCA Peak field values in all of the QLoad reports of all of the APs in OBSSs, including its own.
b) Convert the total peak traffic to a fraction (seconds per second) by multiplying by 32×10^{-6}.
c) Round the resulting fraction value to the nearest 1/64 and enter the result into the HCCA Access Factor field.

For example, if the total overlap traffic is 74 268 (32 μs/s), this is 2.376 576 (seconds/second). Now 2.376 576 × 64 = 152.1 rounded to 152. Hence, the HCCA Access Factor octet, in this case, would be 152 (representing the fraction 152/64).

T.3 Channel selection using QLoad report

T.3.1 General

In addition to the channel selection described below, it is advised that other factors such as traffic from IBSSs, energy from non-IEEE-802.11 systems, and device constraints on the AP or STAs anticipated within the BSS be considered, and regulatory constraints need to be complied with.

The most effective mitigation to OBSS is for an AP to operate on channels that are free or that are occupied by another AP that is not fully loaded with QoS traffic. In the absence of a centralized channel assignment algorithm, an AP should use the Overlap and Potential Traffic Self fields of the QLoad Report element as part of its channel selection procedure. An AP might use the Overlap field and Potential Traffic Self field information when deciding the best channel to select. If there are sufficient channels for an AP to find a channel with no other APs within range, then an AP is advised to select one of them.

When selecting a channel, the AP should scan to see whether there is a free channel taking account of BSS channel width and channel spacing. If a free channel is not available, then it is advised to select channels that have the least number of QoS APs present. There might be more than one channel with the same number of QoS APs present. At this point, the AP is advised to select, in turn, the candidate channels and send a QLoad Request frame to each AP on that channel. The AP is advised to examine the Overlap and Potential Traffic Self fields of the QLoad Report element to make its final selection.

T.3.2 AP with admission control mandatory

If no “empty” channels are available, then an AP with the ACM (admission control mandatory) bit in the EDCA Parameter Set element set for AC_VI or AC_VO should implement a channel selection procedure to share with one or more APs, in the following preference order:

a) Non-QoS AP where the EDCA Parameter Set element is not present in the Beacon frame
b) QoS AP with the ACM subfield set for AC_VI or AC_VO and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element)
c) QoS AP with an HC and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element)
d) QoS AP with an HC and with no indication of support for QLoad reporting
e) QoS AP with the ACM subfield set for AC_VI or AC_VO and with no indication of support for QLoad reporting
f) QoS AP where the EDCA Parameter Set element is present in the Beacon frame and the ACM subfield is not set for AC_VI or AC_VO

T.3.3 AP with an HC

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If no “empty” channels are available, then an AP with an HC should implement a channel selection procedure to share with one or more APs, in the following preference order:

a) Non-QoS AP where the EDCA Parameter Set element is not present in the Beacon frame
b) QoS AP where the EDCA Parameter Set element is present in the Beacon frame and the ACM subfield is not set for AC_VI or AC_VO
c) QoS AP with the ACM subfield set for AC_VI or AC_VO and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element)
d) QoS AP with an HC and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element)
e) QoS AP with the ACM subfield set for AC_VI or AC_VO and with no indication of support for QLoad reporting
f) QoS AP with an HC and with no indication of support for QLoad reporting

T.3.4 Channel selection procedures

Channel selection should be performed as follows:

a) Create a list of the available channels. Typically this is the list of channels allowed by regulation in the operating regulatory domain; however, this list might be modified by management policy (e.g., removing overlapping channels, avoiding radar detect channels).
b) Create an array for each available channel that allows the recording of the QoS AP count, ACM subfield count, HC count, overlap count, and potential load for that channel.
c) Step through the list of available channels, listening for beacons for at least dot11OBSSScanPassiveTotalPerChannel TUs per channel.
d) Upon completion of the scan of a channel, process the beacons received on that channel, filtered to the set of unique BSSIDs:
    1) Using the capabilities signaled in the beacon, modify the QoS AP count, ACM subfield count, HC count, overlap count, and potential load of the channel array for the primary channel indicated in the received beacon.
    2) If the AP is using a channel bandwidth that is greater than the channel spacing (e.g., when using the 2.4 GHz band or when the overlapping AP allows 40 MHz HT PPDUs in its BSS), also update the channel array for channels that are affected by this OBSS. For example, a beacon received on channel 2 indicating a 20 MHz BSS also affects channels 1, 3, and 4.
e) Upon completion of scanning all of the channels, the AP has information on the number of APs and the potential load of each channel, including co-channel BSSs.
f) If the channel array indicates that there are channels with no other APs, one of these “empty” channels should be chosen randomly.
g) Otherwise, create a list of candidate channels by selecting only the channels with the lowest number of QoS APs. For example, if the channel scan procedure indicated that there were two QoS APs on channel 3, three QoS APs on channel 6, and two QoS APs on channel 11, the list of candidate channels would contain 3 and 11.
    1) If this list contains one or more channels with non-QoS APs, then filter the list for the least number of APs.
    2) If this list contains more than one channel, one of these channels should be chosen randomly.
h) If this list contains more than one channel and the AP has been configured to set the ACM subfield for AC_VI or AC_VO:
    1) Filter the list for the minimum count of QoS AP where the EDCA Parameter Set element is present in the Beacon frame and the ACM subfield is not set for AC_VI or AC_VO.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

2) If this list contains more than one channel, filter the list for the minimum count of QoS AP with the ACM subfield set for AC_VI or AC_VO and with no indication of support for QLoad reporting.
3) If this list contains more than one channel, filter the list for the minimum count of QoS AP with an HC and with no indication of support for QLoad reporting.
4) If this list contains more than one channel, filter the list for the minimum count of QoS AP with an HC and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element).
5) If this list contains more than one channel, filter the list for the minimum count of QoS AP with the ACM subfield set for AC_VI or AC_VO and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element).

i) If this list contains more than one channel and the AP has an HC:
1) Filter the list for the minimum count of QoS AP with an HC and with no indication of support for QLoad reporting.
2) If this list contains more than one channel, filter the list for the minimum count of QoS AP with the ACM subfield set for AC_VI or AC_VO and with no indication of support for QLoad reporting.
3) If this list contains more than one channel, filter the list for the minimum count of QoS AP with an HC and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element).
4) If this list contains more than one channel, filter the list for the minimum count of QoS AP with the ACM subfield set for AC_VI or AC_VO and with an indication of support for QLoad reporting (i.e., the QLoad Report field equal to 1 in the Extended Capabilities element).
5) If this list contains more than one channel, filter the list for the minimum count of QoS AP where the EDCA Parameter Set element is present in the Beacon frame and the ACM subfield is not set for AC_VI or AC_VO.

j) If this list contains more than one channel, filter the list to the set of channels with the minimum overlap count.
k) If this list contains more than one channel, filter the list to the set of channels with the minimum potential load.
l) From the remaining channels in this list, randomly choose one of these channels.

T.4 Sharing in an OBSS situation

T.4.1 General

If the EDCA Access Factor is greater than one, then there is a potential overallocation of the WM. APs should avoid overallocation in the channel selection process, but if overallocation exists, then a sharing scheme should be used to provide each AP with a fair share of the bandwidth, but more importantly, so that any already admitted or scheduled QoS streams are not impaired by the addition of streams from any OBSS. The EDCA Access Factor, HCCA Access Factor, and Potential Traffic Self fields in the QLoad Report element are provided to enable sharing schemes to be used.

The sharing scheme also protects an AP from the neighbor capture effect where it has neighbors that are hidden from each other. A major objective of an OBSS sharing scheme is that if a QoS stream is allocated or scheduled, then it is not compromised by the addition of further streams from any OBSS that would cause the medium to be overallocated. This objective is achieved if the APs in OBSSs cooperate.

T.4.2 Sharing schemes

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

T.4.2.1 General

Two sharing schemes are suggested: proportional sharing and on-demand sharing. In each sharing scheme, the purpose is to keep the total allocated traffic to a value where overallocation does not occur. The absolute maximum allocation is 1 s/s (100%). In the following descriptions of the two suggested sharing schemes, this value is referred to as the *maximum allocation value (MAV)*. It is suggested that in order to provide some protection to non-QoS traffic, each AP select a value for MAV:

$$MAV = (M + 1)/(M + N + 1) \text{ s/s} \tag{52}$$

where

M is the number of overlapping APs that are robust AV streaming STAs
N is the number of overlapping APs that are not robust AV streaming STAs

There is no requirement that each AP select the same MAV.

T.4.2.2 Proportional sharing scheme

The proportional sharing scheme described in this subclause is an example of a static sharing policy, as described in Table 9-288 and 11.26.2.2.

When using the proportional sharing scheme, the AP examines the sum of the EDCA Access Factors and HCCA Access Factors in the QLoad reports from each OBSS, including its own Qload report, and determines the maximum. This maximum value is termed the *combined access factor*. If the maximum value from the combined access factor is less than or equal to MAV, the AP is advised to allocate only up to its advertised potential traffic self traffic. If the maximum value from the combined access factor is greater than MAV, then the AP is advised to allocate only up to a value of its potential traffic self divided by the combined access factor, multiplied by MAV.

In the proportional sharing scheme, before an AP allocates a new medium time or schedules a new TXOP in response to an ADDTS Request frame, it checks that this addition does not exceed its sharing limit, as follows:

a) If the EDCA Access Factor is less than or equal to MAV, then the AP allocates up to its advertised potential traffic self, with the composite stream (MAX traffic) calculated as shown in Equation (53).

$$\text{MAX traffic} = \mu_{tot} + 2\,\sigma_{tot} \tag{53}$$

b) If the EDCA Access Factor is greater than MAV, the AP carries out the following:
   1) Calculate the peak traffic value of the potential traffic self using Equation (54).

$$Peak = \mu_{tot} + 2\,\sigma_{tot} \tag{54}$$

   2) Divide this value by the combined access factor and multiply by MAV. This value is termed the *maximum allowable potential traffic self traffic*.
   3) Calculate the resulting value of the allocated traffic self if the new TSPEC is accepted, as explained in T.2.4 (Calculation of allocated traffic self), and then calculate the resulting peak value using Equation (55).

$$Peak = \mu_{tot} + 2\,\sigma_{tot} \tag{55}$$

   4) If the resulting peak value, calculated in step 3), is greater than the maximum allowable potential traffic self traffic, then the AP is advised to reject the ADDTS Request frame.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

5) If the resulting peak value, calculated in step 3), is less than the maximum allowable potential traffic self traffic and the ADDTS Request frame is set for EDCA admission, then the AP is advised to accept the request.
6) The AP then checks that it is possible to schedule TXOPs using the HCCA TXOP advertisement as described in 11.26.3 (HCCA TXOP negotiation).

If the new stream is allocated, then the AP updates the appropriate fields in its QLoad Report element.

T.4.2.3 On-demand sharing scheme

The on-demand sharing scheme described in this subclause is an example of a dynamic sharing policy, as described in Table 9-288 and 11.26.2.2.

The on-demand sharing scheme is as follows:

a) Before allocating a new stream, the AP examines the Allocated Traffic Shared field values in the QLoad reports from each OBSS, including its own Qload report, and selects the maximum Allocated Traffic Shared field value that has the highest peak value, using Equation (56).

$$Peak = \mu_{tot} + 2\,\sigma_{tot} \tag{56}$$

The AP also notes the number of AC_VI and AC_VO streams in this maximum Allocated Traffic Shared field.

b) The AP adds the requested new stream (*new*) to the selected maximum Allocated Traffic Shared field value (*max*) determined in step a), using Equation (57) and Equation (58).

$$\mu = \mu_{new} + Peak \tag{57}$$

$$\sigma = \sqrt{\sigma_{new}^2 + \sigma_{max}^2} \tag{58}$$

c) The AP then calculates the peak value for the new composite stream calculated in step b), using Equation (59).

$$Peak = \mu + 2\sigma \tag{59}$$

d) Using the values of the AC_VI and AC_VO streams noted in step a), plus the stream represented by the new stream, the AP determines the new EDCA Access Factor and then the combined access factor, as described in T.4.2.2.
e) Multiply the peak value calculated in step c) by the EDCA Access Factor, determined in step d). This value is the new peak traffic requirement.
f) If this peak traffic requirement value calculated in step e) is greater than MAV, then the AP is advised to refuse to allocate the new stream.
g) If the peak value calculated in step e) is less than or equal to MAV and the new allocation is for an EDCA admission ADDTS, then the AP allocates that new traffic.
h) If the peak value calculated in step d) is less than or equal to MAV and the new allocation is for an HCCA ADDTS, the AP checks that it is possible to schedule TXOPs using the HCCA TXOP advertisement as described in 11.26.3.

If the new stream is allocated, then the AP updates the appropriate fields in its QLoad Report element.

The Allocated Traffic Self field in the QLoad Report element of a particular AP can be used by other APs as an indication of whether an AP has overallocated or is using an on-demand sharing scheme.

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

If, using either the proportional or on-demand sharing schemes, an AP determines that the acceptance of a TSPEC would exceed the available allocation, or if a non-AP STA has a TSPEC refused, the non-AP STA could always request a new TSPEC that represents a lower medium time or TXOP. This request might be used, for example, where the non-AP STA or AP has the ability to send a more compressed stream.

An AP might choose to use the on-demand sharing scheme until the maximum value of any access factor field in the QLoad Report elements from each OBSS reaches MAV. Once this condition has occurred, the AP could then use the proportional sharing for subsequent ADDTS requests.

T.5 Mitigating consequences of OBSS sharing in presence of noncollaborating devices

The performance of the channel selection and HCAA TXOP negotiation procedures described in this annex and 11.26 might become degraded by the presence of devices that willfully or accidentally behave in an uncooperative manner.

It is suggested that implementations use additional heuristics (e.g., a history of collaboration, traffic monitoring, device configuration, or a combination of such) to assess the accuracy of the information they receive from neighboring APs in order to determine an appropriate collaboration strategy.

An AP that maintains historical information of collaboration results with its neighboring APs could use this information to control its collaboration behavior. For example, an AP might choose to share a channel with an AP that had a history of successful collaboration. In another example, an AP might choose to avoid transmissions only during the HCCA TXOPs of neighboring APs with which it has a history of successful HCCA TXOP negotiation.

When using HCCA TXOP negotiation, it is suggested that an AP perform some monitoring of the channel to assess whether the HCCA AP with which it is collaborating is using its advertised HCCA TXOPs. If the monitoring AP does not detect HCCA traffic during these advertised HCCA TXOPs, such a lack of traffic might indicate that the neighboring AP is willfully or accidentally behaving in an uncooperative manner by advertising HCCA TXOPs that it is not using, possibly as a method to suppress traffic in neighboring BSSs. The monitoring AP might wish to ignore the HCCA TXOP advertisements from APs that do not appear to be collaborating.

Some of the OBSS procedures use unauthenticated Beacon frames and Public Action frames, which are susceptible to impersonation. If unauthenticated Beacon frames and Public Action frames are used, an AP might suffer a denial of service attack by another device impersonating the AP. This denial of service attack, due to the actions of the impersonating device, might cause neighboring APs to falsely ascertain the AP is not collaborating.

An AP could enable protected HCCA TXOP negotiation and protected QLoad reporting to provide protection against impersonation. The AP PeerKey protocol is used in the generation of the PMK to prove that an AP has the private key that corresponds to its public key. Impersonation of protected HCCA TXOP negotiation and protected QLoad report management from an AP is prevented while the AP maintains possession of this private key and this private key is not possessed by any other devices.

T.6 BSS color and spatial reuse

The BSS color is an identifier of the BSS and is used to assist a receiving STA in identifying the BSS from which a PPDU originates so that the STA can follow the channel access rules to perform spatial reuse. The objective of spatial reuse operation is to allow the medium to be used more often between OBSSs in dense deployment scenarios by the early identification of signals from OBSSs and interference management. See 26.10.

Annex U

(informative)

Functions of the centralized coordination service root (CCSR)

Via unspecified means over the DS, a centralized coordination service root (CCSR) performs the following functions:

- Allows APs to enroll or unenroll from the CCSS.
- Provides a directory service, wherein the CCSR responds to a directory service request that includes a MAC address with an indication of whether the MAC address is an S-AP within the CCSS.
- Configures the beacon interval, ClusterMaxMem, Beacon SP duration, TXSS offset, TXSS CBAP duration, and TXSS CBAP MaxMem (see 10.39.2.2) of each S-AP.
- Aligns the rate of increment of TSFs of S-APs within the CCSS.
- Configures the individual TSF offsets of each S-AP in order to minimize the temporal, spatial, and frequency overlap of BHIs of the BSSs in the same CCSS.
- Provides to each S-AP the cluster time offset availability information from nearby co-channel S-APs.
- Configures each S-AP with certain medium access policies for its centralized AP or PCP cluster (see 10.39.3.4). The CCSR is permitted to configure different S-APs with different medium access policies.
- Configures each S-AP with a list of one or more channels in an operating class that the S-AP is excluded from operating upon and that the S-AP advertises via the channel usage procedures (see 11.21.15). The excluded channels are available to STAs that are operating in the area covered by the ECAPC, yet are not within the ECAPC.

Annex V

(informative)

Informative procedures for DMG STAs

V.1 TSPEC aggregation for BMG BSSs

Examples of TSPEC aggregation include, but are not limited to, the following:

— Traffic streams between DMG STA A and DMG STA B, having an access policy of SPCA, even if they flow in opposite directions, sharing an SP allocation created with DMG STA A as Source AID and DMG STA B as Destination AID.

— Traffic streams between DMG STA A and other DMG STAs, having an access policy of EDCA, even if they flow in opposite directions (some having DMG STA A as source and some having DMG STA A as destination), sharing a CBAP allocation created with DMG STA A as Source AID and broadcast Destination AID.

Figure V-1 and Figure V-2 show examples of TSPEC aggregation in a DMG BSS. Note that TSPEC 3 in Figure V-1 (for both SPCA and EDCA cases) can flow only through an RD grant.

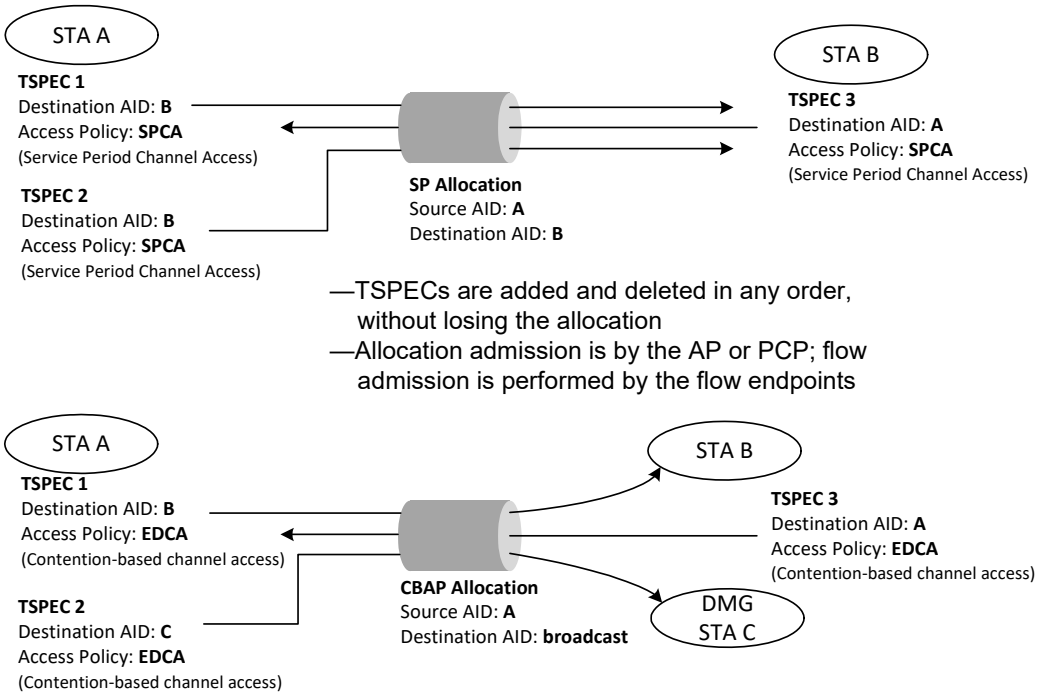

Figure V-1—Example of TSPEC aggregation (SPCA and EDCA access policies)

Copyright © 2025 IEEE. All rights reserved.
Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

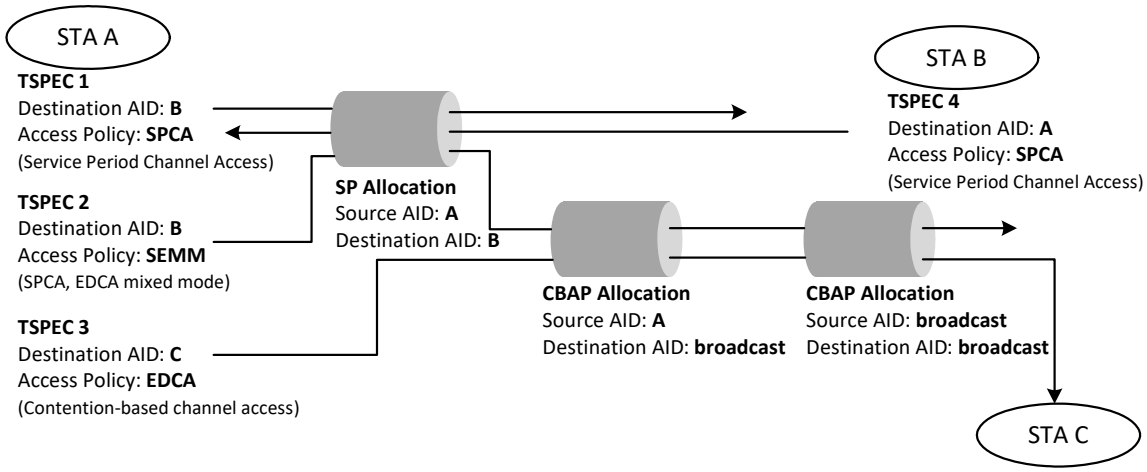

Figure V-2—Example of TSPEC aggregation (SPCA, EDCA, and SEMM access policies)

V.2 Backoff procedure for DMG STAs

Figure V-4 describes the backoff procedure for DMG STAs for the example topology shown in Figure V-3.

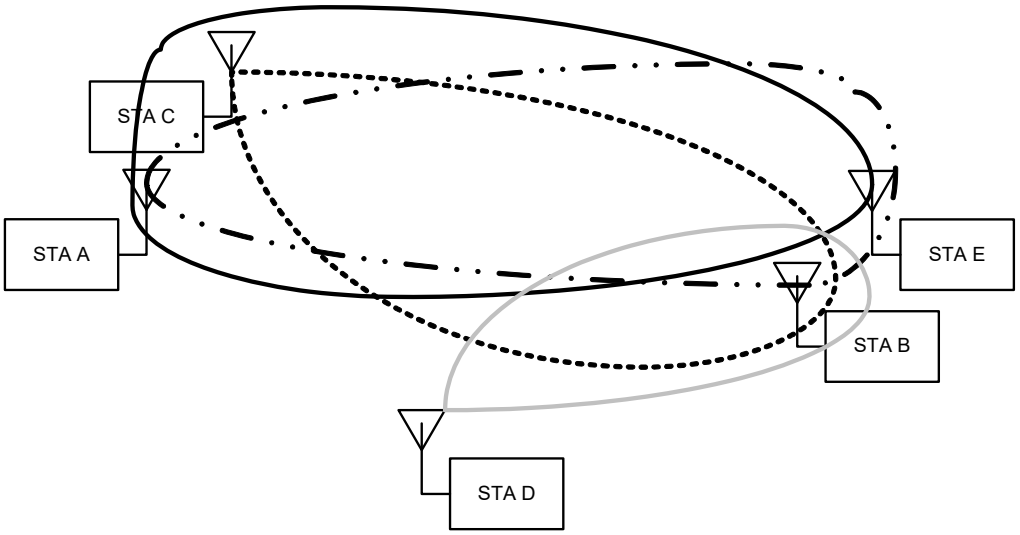

Figure V-3—Example topology of NAV setting in DMG STAs

At the time that STA A starts transmitting a frame to STA E and STA E starts receiving the frame, the antennas of both stations are directed to the peer, i.e., the transmitting antennas of STA A are directed to STA E and the receiving antennas of STA E are directed to STA A. At this point, STA B, STA C, and STA D are not involved in any frame exchange; therefore, they are in receiving state and happen to have the configuration of their receiving antenna arrays set to a quasi-omni antenna pattern to be ready to receive frames from any STA.

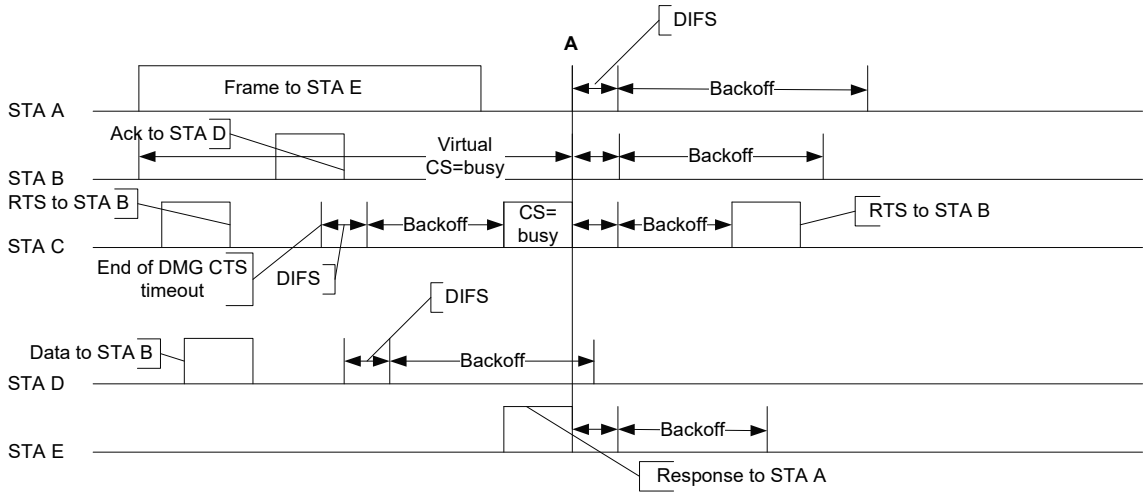

Figure V-4—Backoff procedure for DMG STAs

STA B receives the frame transmitted by STA A (to STA E), and CS (physical and virtual) in STA B indicates a busy medium during the exchange between STA A and STA E.

STA D is not able to receive the frame transmitted by STA A or the response transmitted by STA E; hence CS in STA D indicates IDLE for the duration of the exchange between STA A and STA E.

The physical CS function of STA C indicates a medium busy condition when it receives the response sent by STA E, but indicates an idle medium condition during the transmission from STA A.

STA A and STA E (which are directly involved in the frame exchange), STA B (which received the frame sent by STA A), and STA C (which received the response sent by STA E) are synchronized at point A, where the transaction between STA A and STA E completes.

Since STA D cannot hear the directional transmissions from either STA A or STA C, its physical CS indicates an idle medium condition for the duration of the frame exchange, enabling a frame exchange with STA B at the same time as the frame exchange between STA A and STA E. This is an example of SPSH.

Because STA C is unaware of the transmission of the frame from STA A to STA E, STA C transmits an RTS to STA B. But STA C does not receive a DMG CTS from STA B since the CS at STA B is busy when STA B receives the RTS from the STA C. This causes STA C to retry the RTS transmission following the expiration of a backoff count, which occurs after the completion of the exchange between STA A and STA E.

Annex W

(informative)

Informative procedures for CDMG STAs

W.1 Selection of candidate SPs for spatial sharing

An AP or PCP uses the SSW Report element (9.4.2.221) to construct a beamforming training table. Based on the beamforming training table, the AP or PCP selects a pair of existing SP and candidate SP to perform spatial sharing according to the procedures described in 11.32.

Each entry of the beamforming training table has three items: source AID, destination AID, and the best sector for transmitting from source STA to destination STA. The AP or PCP stores the beamforming training results between any pair of STAs among its BSS. If a source STA and a destination STA have not performed beamforming training, the best sector item is typically given a default sector number.

The select condition is that any source STA involved in an existing SP does not employ the same transmit sector with the one that it employs to communicate with any other STA involved in a candidate SP, and vice versa. If a pair of existing SP and candidate SP satisfies the above condition, the AP or PCP schedules the existing SP and the candidate SP time-overlapping with each other for spatial sharing.

For the same existing SP, if more than one candidate SP satisfy the above condition, the AP or PCP selects the SP with the largest number of difference between any two of transmit sectors employed by a source STA to communicate with its destination STA and with any other STA involved in the other SP.

W.2 N-phase beamforming codebook for CDMG STAs

W.2.1 General

This annex puts forward a method for *N*-phase beamforming codebook design, which is applicable to CDMG STAs only. The codebook cannot only be used in the multi-beam switching system, but also be applied to 1-D (one-dimensional) uniform linear phased antenna array and 2-D (two-dimensional) uniform phased antenna array. The STA can simply choose this beamforming codebook for directional transmission during communication.

W.2.2 1-D (one-dimensional) antenna array

As to the 1-D uniform linear antenna array, all antenna array elements linearly distribute with the interval of λ/2 while λ denotes the carrier's wavelength. The beam codebook is a data matrix **W,** and each element of **W** defines the corresponding antenna array element's weights. For phased antenna array, the weights define the phase misalignment, so the element $w_{m,k}$ of **W** satisfies $|w_{m,k}|=1$. Equation (60) gives an example of a beam codebook matrix, among which *M* denotes the number of antenna elements and *K* denotes the numbers of beam patterns. Each column of the codebook matrix specifies a certain beam pattern, and all columns cover the whole space together. The columns of **W** number from 0.

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

$$\boldsymbol{W}_{M\times K} = \begin{bmatrix} 1 & j & \cdots & 1 \\ 1 & j & \cdots & j \\ \cdots & \cdots & \cdots & \cdots \\ 1 & j & \cdots & 1 \end{bmatrix}_{M\times K} \tag{60}$$

Figure W-1 shows an arrange mode of 1-D uniform linear antenna array.

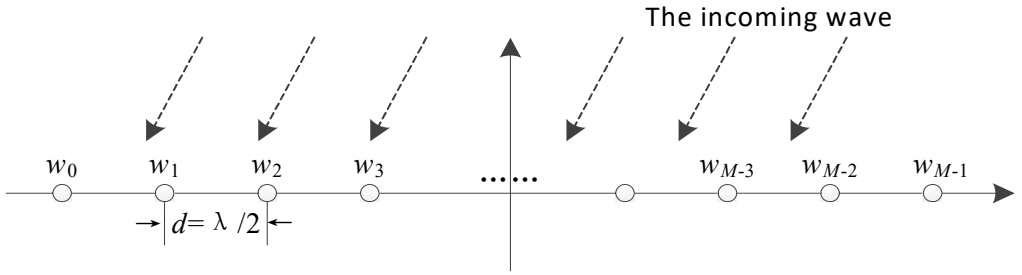

Figure W-1—An arrange mode of 1-D uniform linear antenna array

N-phase beam codebook is shown in Equation (W-1). The matrix's element of line *m* and column *k* denotes the antenna weight for the *m*-th antenna element of the *k*-th beam. *K* is the number of beams, and *M* is the number of antenna elements. The function fix(*x*) returns the biggest integer that is less than or equal to *x*. *N* denotes the number of discrete phases, and the size of *N* is free while each beam gain's loss generated by the codebook is smaller with the increase of *N*. Generally, *N* satisfies $N \geq 4$ (i.e., at least 2 bit discrete phases) to obtain the beam codebook's performance gain. Meanwhile, *N* also satisfies $N \leq 2M$ for no more performance gain is acquired when $N>2M$.

$$W(m,k) = e^{j\frac{2\pi}{N}\mathrm{fix}\left(\frac{m\times \mathrm{mod}(k+K/2,K)}{K/N}\right)} \tag{W-1}$$

$$m = 0, 1, \ldots, M-1;\ k = 0, 1, \ldots$$

Figure W-2 shows the codebook's beam patterns when m=8 and k=16. Figure W-2(a) shows the beam patterns when N=4, and Figure W-2(b) shows the beam patterns when N=16.

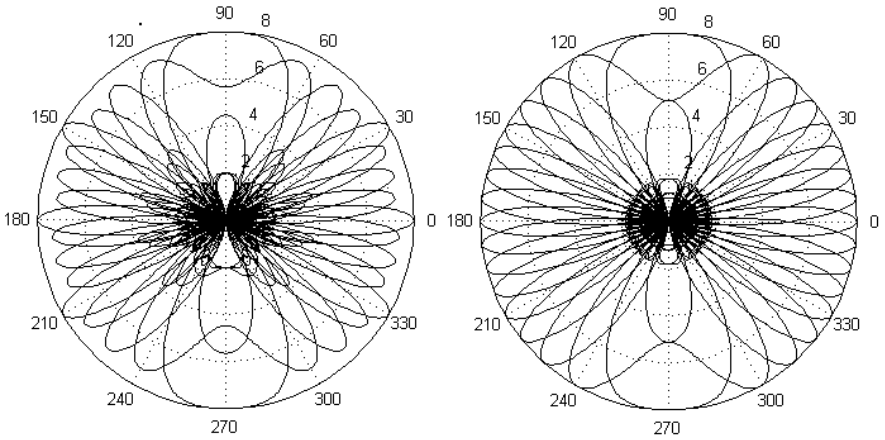

Figure W-2—Beam patterns generated by the codebook

W.2.3 2-D (two-dimensional) antenna array

A beam of 2-D linear antenna array is made up of two mutually perpendicular 1-D uniform linear antenna arrays. Figure W-3 shows an arrange mode of 2-D uniform linear antenna array. The antenna elements are arranged in the mutually perpendicular directions of x and z, and the antenna elements' number in the direction of x is M_x with the spacing of d_x while the antenna elements' number in the direction of z is M_z with the spacing of d_z.

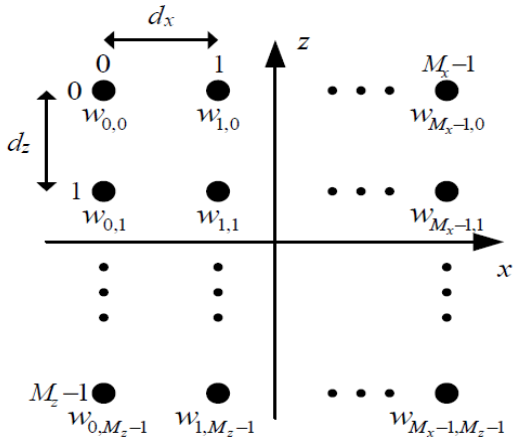

Figure W-3—An arrange mode of 2-D uniform linear antenna array

Each beam pattern of 2-D antenna array is actually superposition of two beam patterns of 1-D antenna array. The weights of antenna elements of 2-D antenna array should be calculated as follows:

$$w_{m_x, m_z} = w_{m_x} w_{m_z};\ m_x = 0, 1, \ldots, M_x, m_z = 0, 1, \ldots, M_z \quad \text{(W-2)}$$

Among which w_{m_x} and w_{m_z} separately stands for the beam weights of x and z.

W.3 Beam tracking and switching for enhanced beam tracking mechanism

This annex puts forward a method of beam tracking and switching for a CDMG STA pair supporting enhanced beam tracking mechanism to combat link blockage and antenna rotation. After enhanced beam tracking is requested, the e-TRN subfields are transmitted in the end of the PHY frame.

The CDMG STA pair measure the receive signal powers corresponding to the training beam links, including the current transmission link, the neighboring beam links and the current alternative beam link.

The signal power attenuation induced by the link blockage is calculated as the difference value of the power obtained by originally optimal beam link minus maximum power obtained by current transmission and its neighboring beam links. If the signal power attenuation induced by the link blockage is larger than a blockage attenuation threshold, or the power obtained by alternative beam link is larger than the maximum power obtained by current transmission and its neighboring beam links, the link blockage is declared.

If antenna rotation is considered, the signal power attenuation induced by the antenna rotation is calculated as the difference value of maximum power of the current transmission and its neighboring beam links minus the power of the current transmission beam link. If the signal power attenuation induced by the antenna rotation is larger than a predefined rotation attenuation threshold, the antenna rotation is declared, and the rotation compensation angle for the subsequent transmission and alternative beam links is calculated as

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

the difference value of the azimuth of the neighboring beam link that has the maximum signal power minus the azimuth of current transmission beam link.

Finally, according to the switching declaration results and the rotation compensation angle, STAs can switch to the AWV, i.e., azimuth, of the updated alternative beam link to combat link blockage and antenna rotation. Specifically, if the link blockage is declared, the azimuth of the subsequent transmission beam link is to become the azimuth of the current alternative beam link plus the rotation compensation angle, and the azimuth of subsequent alternative beam link is to become the azimuth of the current transmission beam link plus the rotation compensation angle; otherwise, the azimuths of subsequent transmission and alternative beam links are to become their current azimuths plus the rotation compensation angle, respectively.

Annex X

(informative)

Link rate considerations

Default values for the link cost determination variables whose names start with “dot11GLKLinkRate” are provided in Annex C. In adjusting the values of these variables, the following considerations are recommended:

— For applications such as bulk data transfer, in which the long-term bandwidth is of primary concern, it is recommended that dot11GLKLinkRateWavg be set near the top of its range while dot11GLKLinkRateWgeo and dot11GLKLinkRateWmin are set low, perhaps to 0. It might also be reasonable to increase some combination of dot11GLKLinkRateSamples and dot11GLKLinkRateWindowSize and decrease dot11GLKLinkRateHysteresis from their default values.

— For time critical applications requiring good performance on short bursts of transmissions, it is recommended that dot11GLKLinkRateWmin be set near the top of its range while dot11GLKLinkRateWavg and dot11GLKLinkRateWgeo be set low, perhaps to 0. It might also be reasonable to decrease dot11GLKLinkRateWindowSize and/or increase dot11GLKLinkRateHysteresis from their default values to make the cost more responsive. dot11GLKLinkRateSamples × dot11GLKLinkRateWindowSize will determine how quickly $R_{composite}$ can spring back from one or more samples of low or 0 effective data bandwidth.

— For general applications that are not time critical but require reasonable performance, for example, messages related to human interaction or the like, it is recommended that dot11GLKLinkRateWgeo weight dominate and dot11GLKLinkRateWmin and dot11GLKLinkRateWavg are set low, perhaps to 0. In this case, it is also recommended that dot11GLKLinkRateSamples × dot11GLKLinkRateWindowSize not exceed typical human response expectations, perhaps 1 s or 2 s.

Annex Y

(informative)

Preassociation discovery (PAD) additional information

Y.1 Preassociation discovery usage models

The preassociation discovery (PAD) and service information procedures (see 11.23) support several ways of obtaining service information. The following subclauses describe two methods: background search and immediate search.

Y.2 Background search

Applications that run in the background on the STA (e.g., automatically receiving sales coupons within messages transmitted from a BSS for which a user has previously signed up) might not require immediate discovery results to be presented to the user. It may be appropriate to prevent non-AP and non-PCP STAs, running such background applications, from performing a solicited PAD procedure.

Solicited PAD has the potential to introduce network congestion, and it is recommended that STAs limit the use of solicited PAD to cases requiring an active search for services. In those cases, it is more effective to perform an unsolicited PAD search, in which an AP or PCP advertises multiple services known to the SIR, while non-AP and non-PCP STAs need respond only if there is a matched service.

The SIR can advertise services through an AP or PCP, using the Service Hash element, and advertise remaining services, using the Service Hint element, in the Beacon or DMG Beacon frame. Alternatively, the SIR can advertise all of the services through an AP or PCP, using either the Service Hash or Service Hint element, in the Beacon or DMG Beacon. Upon receiving a Beacon or DMG Beacon frame, the SIC in a non-AP and non-PCP STA processes the Service Hash and Service Hint elements to verify if there are any potential matching services. Figure Y-1 and Figure Y-2 show two cases where there is a matching service hint.

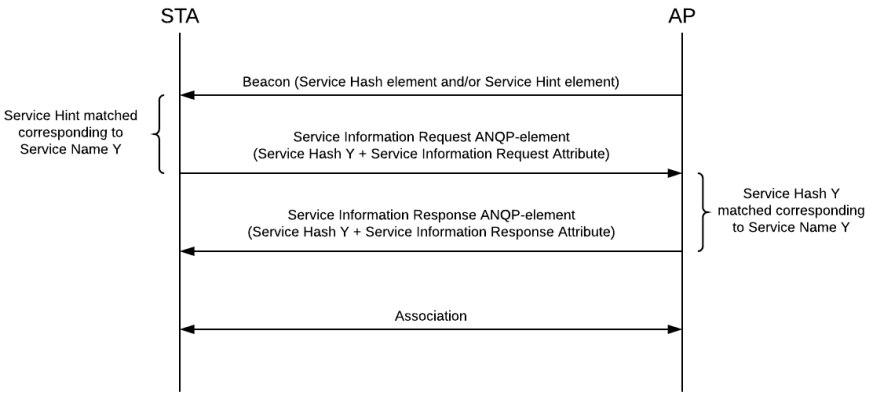

Figure Y-1—Example of a frame exchange for background search with Service Hint matching

Authorized licensed use limited to: zq lv. Downloaded on September 14,2025 at 06:04:32 UTC from IEEE Xplore. Restrictions apply.

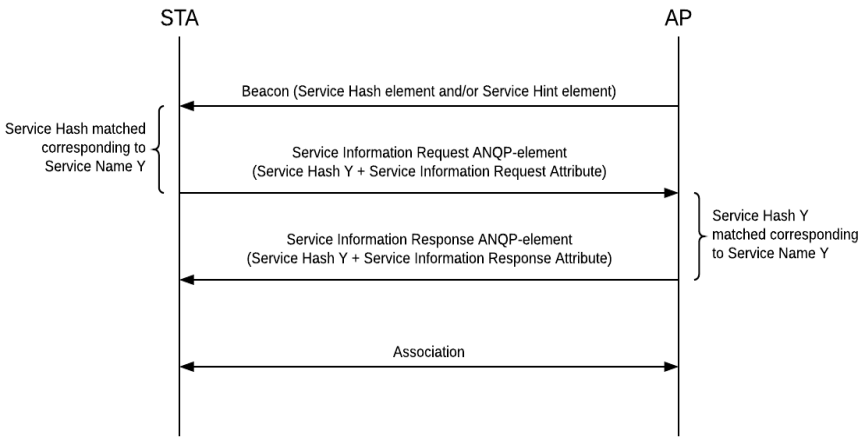

Figure Y-2—Example of frame exchange for background search with matching Service Hash element

If the probability of false positives as indicated in the False Positive Probability Range field of the Service Hint element is considered relatively high by the SIC in the non-AP and non-PCP STA (see Figure Y-1), the SIC can send, through the non-AP and non-PCP STA, a Service Information Request ANQP-element containing Service Information. The SIR then responds, through an AP or PCP, with a Service Information Response ANQP-element containing the Service Information Response Attribute subfield. This subfield contains information about the service(s) that was requested. Following these service information exchanges, the non-AP and non-PCP STA might associate to the AP or PCP.

If the probability of false positive as indicated in False Positive Probability Range field of the Service Hint element is considered relatively low by the SIC in the non-AP and non-PCP STA, the SIC might choose the AP or PCP as a candidate BSS. The SIC might send a Service Information Request ANQP-element to confirm if a service is reachable through the AP or PCP as shown in Figure Y-1. Based on the results of either of these steps, the SIC in the non-AP and non-PCP STA might request association with the BSS.

In a scenario where there is a matching service hash, the non-AP and non-PCP STA can send a Service Information Request ANQP-element containing a Service Information Request Attribute to the AP or PCP to obtain more information about the service from the SIR as shown in Figure Y-2. The SIR responds to the ANQP request, through the AP or PCP, with a Service Information Response ANQP-element containing the Service Information Response Attribute subfield. Following these service message exchanges, the non-AP and non-PCP STA might associate with the AP or PCP. Alternatively, the non-AP and non-PCP STA might choose to associate based on the matching Service Hash element.

Y.3 Immediate search

Applications that are initiated by users on the STA (e.g., a user is looking for a fast movie download service provided by a BSS) require immediate discovery results to be presented to the STA or a user so that network selection can be performed by either a STA or the user to obtain the desired service.

Figure Y-3 shows a non-AP and non-PCP STA performing a solicited PAD procedure, whereby the non-AP and non-PCP STA sends a Service Information Request ANQP-element to query specific services immediately after user initiation of the service/application. The SIR responds through an AP or PCP with a Service Information Response ANQP-element accordingly if there is a matched service.

Figure Y-3—Example of frame exchange for immediate search

Following these service message exchanges, the SIC in the non-AP and non-PCP STA can make an informed decision about choosing to associate to the AP or PCP.

Annex Z

(informative)

HE-SIG-B content examples

Z.1 General

This annex provides a number of examples to illustrate the content of HE-SIG-B content channels.

HE-SIG-B content channels are padded to the same length and to an OFDM symbol boundary as defined in 27.3.11.8.5. For illustration simplicity, the examples do not include the complete padding bits but only pad to make the two HE-SIG-B content channels equal in length and an integer number of 4 bits. All the padding bits in the examples are set to 0.

In the examples, the binary sequence of each HE-SIG-B field is in transmission order. For the entire content of each HE-SIG-B content channel, the binary sequences are converted to hexadecimal listed in transmission order as pairs of hexadecimal digits, where the first bit transmitted is the LSB of the first transmitted octet and is the LSB of the second hexadecimal digit.

Z.2 Example 1

An example of the HE-SIG-B field with resource allocation signaling for an 80 MHz HE MU PPDU is shown in Table Z-1.

Table Z-1—Resource allocation signaling example 1

The AP performs a dynamic split of the User fields for the two MU-MIMO STAs on 484-tone RU 1, with two User fields assigned to HE-SIG-B content channel 1 and none to HE-SIG-B content channel 2, to avoid a disparity in the number of User fields between content channels (see NOTE 1 in 27.3.11.8.3). The User field for STAs 1441, 1442, 1443, and 1444 are in HE-SIG-B content channel 1 while User field for STAs 1445, 1446, 1447, and 1448 are in HE-SIG-B content channel 2. The content of the entire HE-SIG-B field for this example is shown in Table Z-2.

Z.5 Example 4

In the following example there is an 80 MHz or wider PPDU with the lowest 484-tone RU containing two users, and there are multiple other unlisted users, which are variously split across the two HE-SIG-B content channels (e.g., because their RU sizes are up to 242 tones). For the two users in the 484-tone RU, Table Z-7 shows various dynamic split options that can be used to reduce the disparity in the number of User fields across the HE-SIG-B content channels (see NOTE 1 in 27.3.11.8.3). The example shows just the associated RU Allocation subfields (i.e., a fragment of the HE-SIG-B field), which might be sent in one of three ways.

Table Z-7—RU Allocation subfields for different dynamic splits of User fields for the example of two MU-MIMO users in the lowest 484-tone RU of an 80 MHz or wider PPDU

Dynamic split option	First RU Allocation subfield of HE-SIG-B content channel 1	Number of User fields contributed to HE SIG-B content channel 1	First RU Allocation subfield of HE SIG-B content channel 2	Number of User fields contributed to HE SIG-B content channel 2
Both User fields signaled in HE-SIG-B content channel 1	MSB first: 11001001 LSB first: 10010011	2	MSB first: 01110010 LSB first: 01001110	0
Both User fields signaled in HE-SIG-B content channel 2	MSB first: 01110010 LSB first: 01001110	0	MSB first: 11001001 LSB first: 10010011	2
One User field per HE-SIG-B content channel	MSB first: 11001000 LSB first: 00010011	1	MSB first: 11001000 LSB first: 00010011	1

Annex AA

(informative)

Multiple BSSID configuration examples

AA.1 Introduction

This annex provides examples showing the relationship between profile periodicity (indicated by the Full Set Rx Periodicity field in the Multiple BSSID Configuration element) and the DTIM interval (DTIM Period field in the Multiple BSSID-Index element) for a multiple BSSID set as described in 11.1.3.8.3. The examples provide guidance on how an AP might organize the advertisement of nontransmitted BSSID profiles in its Beacon frames if it cannot fit all the profiles in a single Beacon frame (i.e., partial list of profiles) it is advertising. By having the DTIM interval for a nontransmitted BSSID a multiple of the profile periodicity, the profile for that BSSID would always appear in its DTIM beacon. This helps an associated non-AP STA save power as it is able to receive any updates to the profile when it wakes to receive the DTIM beacon.

AA.2 Examples

In the following examples, a BSSID with BSSID-index I, DTIM count of X, and DTIM period of Y is represented as [I] X/Y. A profile appears in every p^{th} Beacon frame; where p is the value carried in the Full Set Rx Periodicity field. Each set of profiles appearing in a Beacon frame amongst the p Beacon frames is identified as set A to set P. In the following examples, a nontransmitted BSSID is considered as active if the AP corresponding to that BSSID has set up a BSS and the information of the BSSID is carried in a Beacon frame of the AP corresponding to the transmitted BSSID in the set. When an AP is advertising a partial list of profiles, the information might not be carried in every Beacon frame (see 11.1.3.8.3). For simplicity, the examples show that the BSSIDs are activated in contiguous order of BSSID-index and appear in the same order in a Beacon frame. In practice, an AP can activate BSSIDs in any order and include a certain BSSID profile in a Beacon frame based on size.

The first example illustrates the case where MaxBSSID Indicator (n) is set to 4 and there are 11 active nontransmitted BSSIDs in a multiple BSSID set. The AP is able to fit up to 3 nontransmitted BSSID profiles in each beacon, and the Full Set Rx Periodicity field is set to 4. Figure AA-1 shows the configuration for DTIM count and DTIM period of each BSSID in this set. With the DTIM period being a multiple of profile periodicity, the AP is able to include a nontransmitted BSSID in its DTIM beacon.

Figure AA-1—Example of partial list of profiles with a profile periodicity of 4

The next example considers the case where MaxBSSID Indicator (n) is set to 4 and there are 15 active nontransmitted BSSID in a multiple BSSID set. In this example, the AP's Beacon frame is able to fit up to 6 nontransmitted BSSID profiles; therefore, the profile periodicity for the set has a value equal to 3. Figure AA-2 shows the configuration for DTIM count and DTIM period of each BSSID in this set. A BSSID profile would be included every third Beacon frame. In addition, since the DTIM interval is a multiple of profile periodicity, it would appear in the DTIM beacon of each profile.

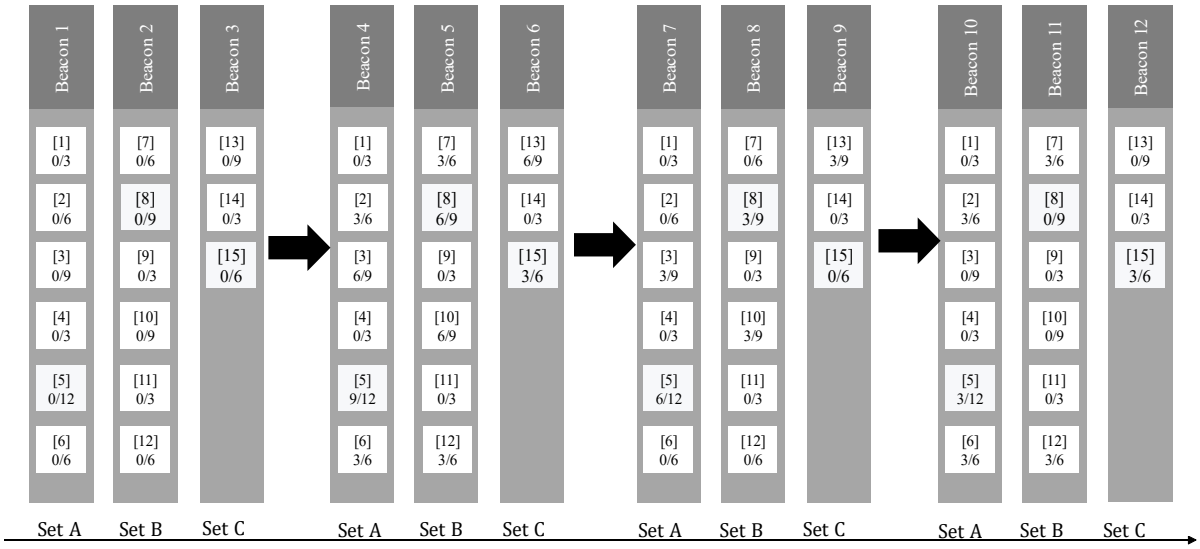

Figure AA-2—Example of partial list of profiles with a profile periodicity of 3

The next example considers the case where a BSSID is deactivated and the corresponding AP disassociates the entire BSS. In this case, there are 15 nontransmitted BSSIDs that are active, and one of the BSSID in set B (BSSID-Index = 10 with DTIM period = 9) is turned off at some point. Figure AA-3 illustrates this case. Once deactivated, this BSSID is no longer included in the Beacon frame. No other BSSIDs in set B or other sets are affected.

Figure AA-3—Example of a BSSID being deactivated

The next example considers the case where a BSSID that was not active earlier is activated. In this case, there are 14 nontransmitted BSSIDs that are active, and a new BSSID (BSSID-Index = 15 with DTIM period = 6) is activated at some point. The AP is able to fit it as part of set C. Figure AA-4 illustrates this case. This BSSID is included in the next set of beacons and is advertised as part of set C. When the BSSID is included in a Beacon frame for the first time, it is started with DTIM count set to 0. With the DTIM Period being a multiple of profile periodicity, the AP can ensure that the profile appears in its DTIM beacon.

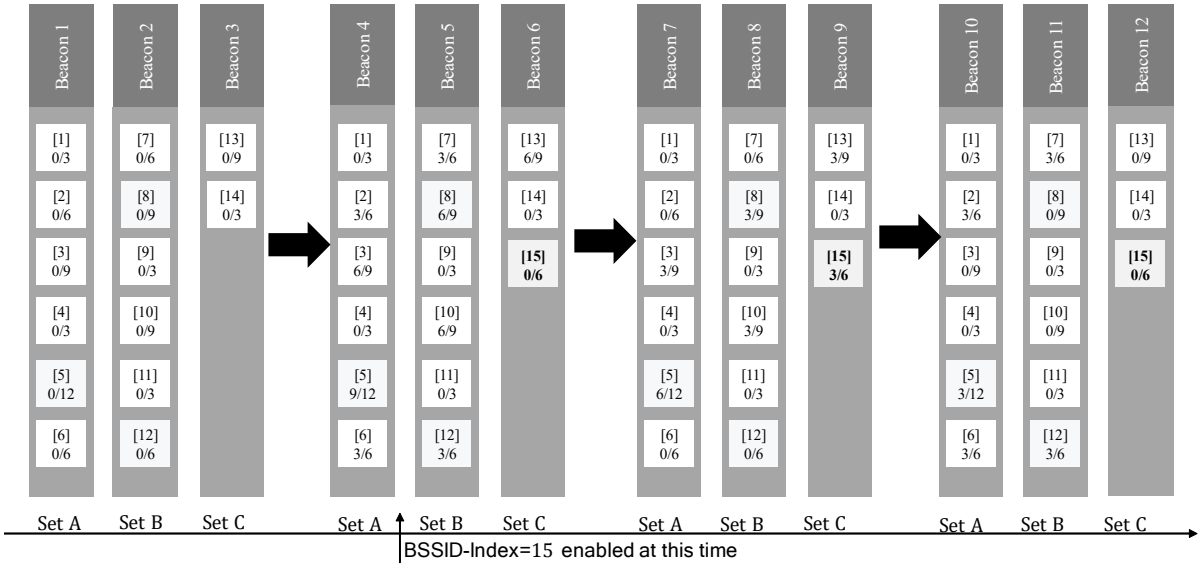

Figure AA-4—Example of a BSSID being activated

The next example considers the case where the DTIM period for a BSSID is updated. In this case, the DTIM period for a BSSID (BSSID-Index = 12) is changed from 6 to 15. This change would be indicated during a DTIM beacon for that profile. This ensures that STAs associated with that profile are able to receive the update. After the change, when the BSSID is included in a Beacon frame for the first time, it starts with

DTIM count set to 0. With the new DTIM period (of 15) being a multiple of profile periodicity (of 3), the profile will appear in its DTIM beacon. Figure AA-5 shows the configuration for DTIM count and DTIM period of each BSSID in this set.

Annex AB

(informative)

Radar implementation using the DMG PHY and EDMG PHY

A radar is used to estimate the relative position and velocity of a target object with respect to the radar by transmitting a signal from a transmitting antenna and measuring the time and direction in which one or more reflections of the signal arrive at a receiving antenna. Given their directional propagation characteristics, the DMG PHY and EDMG PHY can be used to implement radar functionality.

To implement radar functionality, a STA (non-EDMG STA or EDMG STA) can transmit a PPDU and measure the time it takes and direction from which reflections arrive at the STA. Any type of PPDU can be used by the STA as long as the following conditions are met:

— The PPDU is a valid EDMG or DMG PPDU constructed according to the EDMG or DMG PHY specification, respectively
— The STA follows all corresponding medium access rules to transmit the PPDU.
— The TA field and RA field of the frame in the PPDU are set to the MAC address of the transmitting STA.
— For a Short SSW PPDU, the source AID field and Destination AID field of the PPDU are set to the same value.

By using the approach described in this Annex to implement radar function, coexistence with DMG and EDMG transmissions on the same channel is achieved due to the use of IEEE 802.11 EDCA medium access rules and DMG or EDMG PPDUs, which allow other STAs to determine the duration of a transmission. The addressing rules described above enhance coexistence by reducing the probability that a STA gets confused by radar transmissions. When radars follow these rules, the throughput of a DMG or an EDMG STA operating in the vicinity of the radar transmissions can increase due to reduced collisions with such transmissions.

Examples of transmissions that can be used to realize radar functionality include the following:

— A STA may transmit an SSW frame with both the RA field and the TA field set to the MAC address of the transmitting STA to implement radar functionality. In this case, the TXVECTOR parameter TRN_LEN, if the frame is transmitted with the DMG PHY, or the EDMG_TRN_LEN, if the frame is transmitted with the EDMG PHY, may be set to a nonzero value.
— A non-PCP and non-AP EDMG STA may transmit a Short SSW PPDU with both the TXVECTOR parameter SSW_SOURCE_AID and SSW_DESTINATION_AID set to the AID of the transmitting STA to implement radar functionality.
— An EDMG PCP STA or an EDMG AP STA may transmit a Short SSW PPDU with both the TXVECTOR parameter SSW_SOURCE_AID and SSW_DESTINATION_AID set to the BSS AID of the transmitting STA to implement radar functionality.

Annex AC

(informative)

Examples of WUR OOK Symbol Design and CSD Design using MC-OOK modulation

Subclauses 30.3.4.1, 30.3.4.2, and 30.3.4.3 provides a description of how the 2 μs duration WUR OOK and 4 μs duration WUR OOK On and Off symbols might be constructed using MC-OOK modulation but does not provide the actual frequency domain sequences for those symbols. This annex provides example sequences for the construction of these symbols using MC-OOK modulation.

Table AC-1 provides example sequences for the construction of the 2 μs duration WUR OOK On symbol using MC-OOK modulation.

Table AC-1—Example Values for the Sequence S^{HDR} used for the Construction of the 2 μs duration WUR OOK On symbol using MC-OOK modulation

Index	Sequence S^{HDR}
Example 1	$\frac{\{1, 0, -3, 0, -3, 0, 0, 0, -3, 0, -3, 0, 1\}}{\sqrt{6.333}}$
Example 2	$\frac{\{3 + 7j, 0, 1 + 15j, 0, -5 + 13j, 0, 0, 0, 13 - 5j, 0, -15 - 1j, 0, 7 + 3j\}}{\sqrt{159.333}}$
Example 3	$\frac{\{3 + 5j, 0, -7 + 5j, 0, -7 - 5j, 0, 0, 0, -5 + 1j, 0, 7 + 7j, 0, 5 - 5j\}}{\sqrt{80.8}}$
NOTE—For all three examples, the scaling factors are chosen so that the WUR OOK On symbol is normalized to have the same power as the other examples.	

Example 1 in Table AC-1 is evaluated under a number of channel conditions and shows consistent good performance in both multipath fading and additive white Gaussian noise channels. This sequence also has low PAPR for a single channel transmission. The WUR OOK symbols generated using this sequence meet the correlation test in 30.3.12.5.

Example 2 in Table AC-1 is designed to provide good performance in commonly found propagation conditions, including the additive white Gaussian noise channel. This WUR OOK On symbol has nearly constant envelope and power distributed over the full bandwidth. Therefore, it might be transmitted with an output power higher than during the L-STF, L-LTF and L-SIG. The sequence meets the correlation test in 30.3.12.5.

Example 3 in Table AC-1 is found to provide good performance through exhaustive search among the OFDM symbols with BPSK modulation. This sequence is optimized for good tradeoff between multipath fading channel performance and PAPR. The WUR OOK symbols generated using this sequence meet the correlation test in 30.3.12.5.

Table AC-2 provides example sequences for the construction of the 4 μs duration MC-OOK On symbol.

Table AC-2—Example Values for the Sequence S^{LDR} used for the Construction of the 4 μs duration WUR OOK On symbol using MC-OOK modulation

Index	Sequence S^{LDR}
Example 1	$\{-1, 1, 1, 1, -1, 1, 0, -1, -1, -1, 1, -1, -1\}$
Example 2	$\frac{\{1+j, -1+j, -1+j, 1+j, -1+j, 1-j, 0, 1+j, 1+j, 1-j, 1+j, -1-j, -1+j\}}{\sqrt{2}}$
Example 3	$\frac{\{-1+j, 1+j, -1+j, 1+j, -1-j, 1-j, 0, 1-j, 1+j, -1-j, -1-j, 1+j, 1+j\}}{\sqrt{2}}$
NOTE—For Example 2 and Example 3, the scaling factors are chosen so that the MC-OOK On symbol is normalized to have the same power as the other examples.	

Example 1 in Table AC-2 is evaluated under a number of channel conditions and shows consistent good performance in both multipath fading and additive white Gaussian noise channels. The WUR OOK symbols generated using this sequence meet the correlation test in 30.3.12.5.

Example 2 in Table AC-2 is designed to provide good performance in commonly found propagation conditions, including the additive white Gaussian noise channel. This WUR OOK On symbol has a nearly constant envelope and has power distributed over the full bandwidth. Therefore, it might be transmitted with an output power higher than during the L-STF, L-LTF and L-SIG. The WUR OOK symbols generated using this sequence meet the correlation test in 30.3.12.5.

Example 3 in Table AC-2 is found to provide good performance through exhaustive search among the OFDM symbols with BPSK modulation. This sequence is optimized for good tradeoff between multipath fading channel performance and PAPR. The WUR OOK symbols generated using this sequence meet the correlation test in 30.3.12.5.

For the WUR-Sync field and the HDR WUR-Data field, which are both constructed from 2 μs duration WUR OOK symbols, Table AC-3 provides recommended CSD values T_{CS}^{HDR} for one to eight transmit antennas, for each of the three recommended WUR OOK symbols from Table AC-1.

For the LDR WUR-Data field, which is constructed from 4 μs duration WUR OOK symbols, Table AC-4 provides recommended CSD values T_{CS}^{LDR} for one to eight transmit antennas, for each of the three recommended WUR OOK symbols from Table AC-2.

Annex AD

(informative)

Phase shift feedback calculation

Assume there is a single Tx and Rx RF chain between the initiating STA (ISTA) and responding STA (RSTA) and denote the frequency domain channel estimation of I2R NDP and R2I NDP as a column vector $h = [h_1, h_2, \ldots, h_N]^{\mathrm{T}}$ and N is the number of subcarriers, then the corresponding phase shift might be calculated from Equation (AD-1).

$$PS = -\frac{\text{angle}(h_0^{\mathrm{H}} h_K)}{2\pi K \Delta_{F,\,\text{HE-LTF}}} + t_{\text{HE-LTF, DFT boundary}} - T_{\text{GI, HE-LTF}} - T_{\text{HE-STF}} - T_{\text{Pre-HE portion}} \quad \text{(AD-1)}$$

where

h_0 is $[h_1, h_2, \ldots, h_{N-K}]^{\mathrm{T}}$

h_K is $[h_{K+1}, h_{K+2}, \ldots, h_N]^{\mathrm{T}}$

$(\ldots)^{\mathrm{T}}$ denotes the transpose of a vector

$(\ldots)^{\mathrm{H}}$ represents the Hermitian transpose of a vector

angle(…)is the phase angle of a complex number

K is implementation specific

$\Delta_{F,\,\text{HE-LTF}}$ is the frequency subcarrier spacing for the HE-LTF field

$t_{\text{HE-LTF, DFT boundary}}$ is the timing boundary of the DFT window for the HE-LTF symbol expressed in the receiver's local clock

$T_{\text{GI, HE-LTF}}$ is the guard interval duration for the HE-LTF portion

$T_{\text{HE-STF}}$ is the HE-STF field duration in Ranging NDP or TB Ranging NDP

$T_{\text{Pre-HE portion}}$ is the duration of the pre-HE portion in the preamble of a Ranging NDP or TB Ranging NDP

Channel estimates might be filtered for noise reduction and ranging accuracy improvement before they are applied in Equation (AD-1).

When the ISTA and RSTA have multiple Tx and Rx chains, the frequency domain channel estimation vector between the *i*th Tx spatial stream and *j*th Rx antenna is denoted as $h_{i,j} = [h_{i,j,1}, h_{i,j,2}, \ldots, h_{i,j,N}]^{\mathrm{T}}$, and the phase shift is calculated from Equation (AD-2).

$$PS = -\frac{\text{angle}\left(\sum_i \sum_j h_{i,j,0}^{\mathrm{H}} h_{i,j,K}\right)}{2\pi K \Delta_{F,\,\text{HE-LTF}}} + t_{\text{HE-LTF, DFT boundary}} - T_{\text{GI, HE-LTF}} - T_{\text{HE-STF}} - T_{\text{Pre-HE portion}} \quad \text{(AD-2)}$$

where

$h_{\mathrm{i,j,0}}$ is $[h_{i,j,1}, h_{i,j,2}, \ldots, h_{i,j,N-K}]^{\mathrm{T}}$

$h_{i,j,K}$ is $[h_{i,j,K+1}, h_{i,j,K+2}, \ldots, h_{i,j,N}]^{\mathrm{T}}$

Annex AE

(informative)

SIR-based attack detection

The presence of an attack signal will cause the receiver SINR to drop. Given a measured noise floor, the SINR can be mapped to a signal to interference ratio (SIR). In this annex, an analysis is shown to illustrate the impact of an attack signal on the SIR drop.

Assume that an attacker observes the Secure HE-LTF symbol for a duration of T_{ob}, referred to as the observation period; see Figure AE-1. The attacker can use these observations to generate an attack signal over the duration T_c, referred to as the computation period. Finally, the attacker will transmit the attack signal during the attack period, T_a, to create a false first path of arrival that has an earlier arrival time than the true first path of arrival.

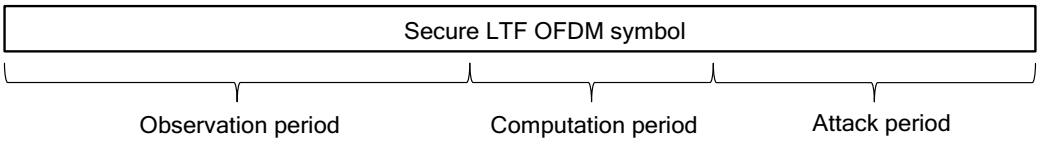

Figure AE-1—Attacking secure HE-LTF symbols

A side effect of creating the false first path of arrival is that the attacker will also generate interference at the intended receiver. If we assume that the attack signal has a correlation of ρ with the true Secure HE-LTF signal and creates a false first path of arrival with a relative power level of *FFP* (dB), then the signal-to-interference ratio (SIR) that is seen by the intended receiver will be:

$$SIR(\text{dB}) = -FFP(\text{dB}) + 10\log_{10}(\rho^2 T_a) - 10\log_{10}(1 - \rho^2 T_a)$$

When an attack signal is present, the interference introduced by the attack signal will lead to an SIR drop and the value will depend on the relative power level of *FFP*, correlation, and attack period.

For example, if *FFP* = –10 dB, then the expected SIR levels for different values of ρ and T_a are shown in Figure AE-2.

From this figure, we see that as the correlation of the attack signal decreases or the attack duration decreases, the SIR will drop even further.

Therefore, the presence of an attack signal can be detected by looking for drops in the SIR over a single, or multiple, HE-LTF repetitions. The exact details of the algorithm are left to the implementer.
